The rate of absorption of water by Bakelite. II. GENEVA LEOPOLD AND JOHN JOHNSTON. *J. Phys. Chem.* **32**, 876-8(1928).—The rate of increase in wt. of brown Bakelite strips 42, 71 and 139 mils thick, on immersion in distd. H_2O was measured. A 6% gain in wt., attained in about 28 months by the 42-mil strip, represented satn. The results are expressed in such a way that one may predict from the curve that sheets 140 mils thick would not attain satn. in 26 years. The rate of penetration of H_2O into this type of Bakelite is so slow that under all ordinary atm. conditions the amt. of H_2O absorbed would be negligible. From these expts. alone little may be said as to the mechanism of the absorption.

R. L. DODGE

Studies on the stability of suspensions of coarse particles dispersed in solution. III. Influence of concentration of disperse phase and of salt on clarification. HANS WERNER. *Ber.* **61B**, 802-9(1928).—The process of coagulation is divided into (1) coagulation of disperse particles to form aggregates, (2) pptn. of particles, (3) formation and pptn. of the sediment, (4) accompanying processes, (5) formation of peculiarly structured sediment, (6) foam formation and (7) particles half suspended clinging to the walls of the container. Diagrams explain the effect of salt concn. on kaolin suspensions. Such suspensions may be either reversible or irreversible in coagulation, although large particles are usually reversible. The structure of the deposit depends on the concn. of both salt and disperse phase. Increase in concn. of salt or disperse phase increases the tendency to foam.

RAYMOND H. LAMBERT

Ferric oxide filaments obtained by desiccating colloidal solutions. PAUL BARY. *Compt. rend.* **186**, 1539-41(1928). Ferric oxide hydrosols are made by hydrolyzing a 10% $FeCl_3$ soln. and dialyzing through a cellophane membrane for ten days. A small quantity of the sol when brought to dryness in an oven at 50-60° leaves tiny fragile filaments in concentric rings. A more dil. sol which had been dialyzed longer showed radial rather than concentric filaments. B. ascribes an elongated shape to the particles in the sol and explains the formation of filaments by assuming that the particles are attracted to the container-sol junction by capillary forces.

WILLIAM F. EHRET

The effect of temperature on the rate of flocculation of colloids. K. JABLECZYNSKI AND M. KNASTER. *Bull. soc. chim.* **43**, 156-9(1928). J. and K. det. the rate of flocculation of $Fe(OH)_3$ by KCl at different temps. by measuring the increase in opacity of the sol (cf. Jableczynski, *C. A.* **21**, 684). With 10 cc. of $Fe(OH)_3$ soln. contg. 7.435 g. Fe per l. and 10 cc. of 0.2 N KCl, the const. K is: 0.26, 0.54, 1.31 and 2.58, resp., at 5, 15, 25 and 35°. The temp. coeff. of K is 2.19. According to Schmoluchowski, coagulation is caused by shock of the particles, and depends, therefore, on the rate of diffusion. The latter increases only 30% per 10°; other factors must, therefore, affect coagulation.

G. CALINGAERT

Kinetics of coagulation of colloids. K. JABLECZYNSKI AND M. SOROCZYNSKI. *Bull. soc. chim.* **43**, 159-63(1928).—The rate of coagulation of colloids measured photometrically, is governed by the equation $\log t_{\alpha} - \log t_{\alpha\infty} = Kt$ (cf. Jableczynski, *C. A.* **21**, 684). However, K remains const. only if the limiting value of the angle of rotation is nearly 90°, or corresponds to a high degree of opacity. A more general equation postulates that the rate of increase in opacity is proportional to the difference between the opacity at a given time and the final opacity. This gives: $\log \{(\log t_{\alpha\infty} - \log t_{\alpha})/(\log t_{\alpha\infty} - \log t_{\alpha})\} = Kt$, of which the first equation is only a special case. The general equation was tested by using 2 vols. of $Fe(OH)_3$ soln. (2.04 g. Fe/l.) and 1 vol. of 0.4 N KCl, at 15°, under yellow light.

Thickness of colloid	50 mm.	30	20	10	5
α_{∞}	About 90°	87.5°	86.6°	80.4°	67.3°
Total time, min.	3	7	10	9	27
$K \times 10^3$	174	97.6	67.9	850-42	34-15
$K_1 \times 10^4$				28.0	29.8

Low values of α_{∞} increase the time required for flocculation, but also affect the actual value of K_1 . It would seem preferable therefore to use values of α_{∞} close to 90°, in order to obtain more comparable values of K when studying the kinetics of flocculation.

G. CALINGAERT

The stability of colloidal solutions in the presence of electrolytes. A. BOUTARIC. *Bull. soc. chim.* **43**, 146-55(1928).—All the methods of detg. the stability of colloidal solns. towards electrolytes which are based on the observation of flocculation are in-

accurate and incorrect. B. measures the increase in coeff. of absorption of the colloidal soln. during the time between the addn. of the electrolyte and the flocculation, by means of a Fery spectrophotometer. The opacity increases at a decreasing rate, tending asymptotically towards a limiting value in the neighborhood of which the sol becomes very unstable. Temp. affects the rate of flocculation in either way, depending on the electrolyte. Strong agitation sometimes accelerates flocculation, while darkness or irradiation with light of various wave lengths does not affect the rate of increase in opacity. The rate of flocculation depends not only on the final concn., but also on the concn. at which the electrolyte is added, usually decreasing with a decrease in initial concn. of electrolyte, until a limit is attained for a certain diln. The stability of a soln. is detd. by measuring the time t required for flocculation with increasing concns. C of electrolyte. The curve t vs C has an asymptote parallel with the t axis, and corresponding to the min. concn. of electrolyte which will cause flocculation. The curve is fairly well expressed in the neighborhood of the asymptote by $C = acm.t$. By plotting $\log C$ vs $1/t$, a straight line is obtained which for $1/t \rightarrow 0$ gives the value of $\log a$. Another satisfactory equation is $(C - a) = Kt^n$, which can be plotted as $\log (C - a)$ vs. $\log t$. When multivalent electrolytes are used, some sols show 2 zones of flocculation, with two or three corresponding limiting concns. of stability. The addition of minute amts. of some foreign substances may greatly affect the stability of colloids. Very low concns. of so-called protective colloids (gelatin, albumin, etc.) actually accelerate flocculation, while very high concns. may cause flocculation in the absence of electrolytes. Small concns. of some electrolytes may act as a protective agent for the pptn. by other electrolytes. Finally, the prior addn. of a given electrolyte in an amt. insufficient to cause flocculation, may protect the colloid against flocculation by an amount of the same electrolyte in excess of the min. concn. which will ppt. the untreated colloid. G. C.

The conductivity of copper hydrosols. H. MURFREY D. MURRAY. *J. Chem. Soc.* 1928, 1235-9. Measurement of the cond. of metal hydrosols was undertaken to exam. the ionic equil. in such sols. The concn. of the stabilizing electrolyte was so large that no evidence could be obtained on the equil. between the ions on the particle surface and those in soln. Cu sols give a considerably smaller cond. than Pt or Ag sols. When NaCl soln. is added to a Cu sol the cond. of the mixt. is nearly equal to the sum of the calcd. cond. of its components. With NaOH and other hydroxides and with HNO_3 and AlCl_3 the cond. of the mixt. is less than that of its components while with Na_3PO_4 it is greater. The surface in Cu hydrosols is covered by $\text{Cu}(\text{OH})_2$, which sats. the water in which the particles are dispersed. J. S. REICHERT

Contribution to the study of colloidal clay. A. DEMOLON AND G. BARBIER. *Riv. gen. colloid.* 6, 29-31 (1928), cf. *C. A.* 22, 710, 836. A discussion of previously reported observations on the viscosity and the adsorption power of clay suspensions is given which leads to a partial explanation of the structural transformations produced under different influences. H. M. McLAUGHLIN

Comparative studies of sols made by peptizing iron oxides with silicic acid. A. FODOR AND A. REIFENBERG. *Kolloid Z.* 45, 22-31 (1928). Ferric oxide sols were made (1) by peptizing hydrous ferric oxide with silicic acid, (2) by peptizing ferrous oxide with silicic acid and oxidizing with H_2O_2 , and (3) by mixing colloidal ferric oxide with silicic acid. (1) was colored brick red, (2) was green before oxidation and red-yellow after and (3) was brown-red. The final concn. of each sol was Fe_2O_3 , 0.028% and SiO_2 , 0.18%. The micelles of all carried a negative charge. The av. particle sizes in μ were (1) 3.375, (2) 2.221 and (3) 0.672; the relative viscosities were 1.0143, 1.0208 and 1.0400 in the same order. Max. alkali adsorption is given as 13×10^{-3} equivalents for (1) and 8×10^{-3} for (2). J. G. McNALLY

The influence of mercaptans on the stability of colloidal sulfur solutions. EICHENWASE. *Kolloid Z.* 45, 31-6 (1928). Colloidal S sols. contg. 1.25 millimoles per l. were prepd. by mixing a 0.4% alc. soln. of S with aq. solns. of EtSH of various concns. The sols, with a final concn. of approx. 0.004 millimoles per l. of EtSH showed greater stability than sols. contg. either a greater or less amt. of mercaptan. At low concn. of EtSH the suspension is destroyed by the clumping of the S particles, while the mercaptan dissolves the S at high concn. J. G. McNALLY

Slow hydrolysis of ferric chloride. E. HEYMANN. *Z. anorg. allgem. Chem.* 171, 18-41 (1928). The hydrolysis of FeCl_3 was studied by ultrafiltration and cond. measurements. There is an apparent equil. in the amt. of colloid formed by complete hydrolysis at 80° , and subsequent aging at a lower temp. and by aging a fresh soln. at the lower temp. The Cl content of the colloid is not the same in the two cases. Theories to account for the results are presented. G. B. TAYLOR

The optical activity and colloidal behavior of aqueous gelatin dispersions. ELMER

O. KRAEMER AND J. R. FANSELOW. *J. Phys. Chem.* **32**, 894-911(1928).—The optical rotation of gelatin was studied at various temps., with change in p_H and in the presence of electrolytes. Very different results occur in the sol form than in that of the gel. Gel formation in dil. solns. produces mutarotation and a high sp. rotation. A discussion is given of the internal structure of gel as deduced from exptl. results. R. H. L.

Viscosity factor in emulsification. R. C. SMITH. *Phil. Mag.* [7], **4**, 820-8(1927). —Solids giving good emulsifiability give, as a rule, high interfacial tensions. G. G.

Optical isomers of cystine and their isoelectric solubilities. JAMES C. ANDREWS AND EDWIN J. DE BEER. *J. Phys. Chem.* **32**, 1031-9(1928).—Cystine from its structure should have 2 optical isomers, a meso-compd. and possibly a racemic compd. Soly. varies with size of sample, indicating presence of more than 1 phase. All 4 pos. forms are shown to be present and the calcd. soly. figures suggest that *d*-cystine is 4 times as sol as *l*-cystine. A. P. SACHS

Magnetic susceptibility and the supposed second isoelectric point of gelatin. M. FALLOT. *Compt. rend.* **186**, 1287-8(1928). L. W. RIGGS

The theory of the process of solution. HANS SCHWERDTFEGGER. *Chem. App.* **15**, 73-4, 99-100, 123-5(1928).—A mathematical paper on soln. with and without stirring, with formulas for the detn. of consts. J. H. MOORE

Liquid ammonia as a solvent and the ammonia system of compounds. I. Liquid ammonia as a solvent. W. CONRAD FERNELIUS AND WARREN C. JOHNSON. *J. Chem. Education* **5**, 664-70(1928).—A résumé of the work of Franklin and Kraus and their collaborators, comparing the behavior of H_2O and NH_3 and showing the remarkable results obtained in metathetic reactions in NH_3 solns. This solvent is dissocd. to only 5×10^{-11} Kohlrausch units, or less than one-one thousandth as much as water; thus "ammonolysis," the ability to reverse the neutralization reactions by which salts of weak acids or weak bases are formed, is much weaker than the similar power (hydrolysis) of water. Salts like $Al(CN)_3$ can, therefore, be prepd. in NH_3 , but not in aq. solns. W. C. EBAUGH

The solubility of cadmium sulfide in hydrochloric acid. MAURICE AUMERAS. *Compt. rend.* **186**, 1541-3(1928).—The soly. is detd. under an atm. of N to eliminate any oxidation of H_2S . The following relation expresses the soly. in dil. HCl soln. at 16° : $[HCl] = 970\sqrt{[H_2S][CdCl_2]}$. $[HCl]$, etc., represent total concn. This expression is in accord with the idea of complete dissocn. of the HCl and the $CdCl_2$ in dil. soln. It also shows that in the dil. solns. employed the H_2S undergoes practically only primary dissocn. WILLIAM F. EHRET

Solubility of lead monoxide and basic lead carbonate in alkaline solution. MERLE RANDALL AND HUGH M. SPENCER. Univ. Calif. *J. Am. Chem. Soc.* **50**, 1572-85(1928).—The solubilities of red (tetragonal), yellow (orthorhombic) and hydrated PbO , and $Pb_2(OH)_2(CO_3)_2$ are detd. in dil. aq. KOH solns. at 25° . The assumption that the activity coeffs. of the $HPbO_2$ and NO_3 ions are equal in dil. solns. is found to be approx. correct. The free energies of formation of the $HPbO_2$ ion from the OH ion and the red and yellow forms of PbO , and those for the reactions between $PbO \cdot \frac{1}{2}H_2O$ and $Pb_2(OH)_2(CO_3)_2$ and the OH ion are detd. from extrapolated values of the resp. equil. consts. J. BALOZIAN

The solubility of thallos chloride in water and aqueous solutions of magnesium sulfate and lanthanum nitrate at 25° . MERLE RANDALL AND K. S. CHANG. Univ. of California. *J. Am. Chem. Soc.* **50**, 1535-6(1928).—The soly. of $TlCl$ is detd. in H_2O , in aq. $MgSO_4$ and aq. $La(NO_3)_3$ solns., at 25° , by the method of Randall and Vietti following abstract, equil. being approached from both sides. The soly. of $TlCl$ in H_2O , at 25° , is detd. as 0.01611 moles $TlCl$ per 1000 g. H_2O , the sp. gr. 1.0034 and $d.$ as 1.0004. J. BALOZIAN

The solubility of lead bromide in aqueous salt solutions and the calculation of the activity coefficient from solubility measurements. MERLE RANDALL AND WILLIAM V. A. VIETTI. Univ. California. *J. Am. Chem. Soc.* **50**, 1526-34(1928).—An accurate method of detg. solubilities is developed and is used for those of $PbBr_2$ in aq. solns. of $Pb(NO_3)_2$, $Ba(NO_3)_2$, $CdBr_2$ and KBr , at 25° . A method for detg. the activity coeff. from soly. data by graphical treatment is described, applications being made to $PbBr_2$ and $TlCl$. The use of this method is justified if the satg. salt is non-associated or when the soly. is very small, but may lead to considerable error with fairly sol. associated salts as $PbBr_2$. J. BALOZIAN

The activity coefficients of ions in aqueous solutions of nonelectrolytes. J. N. BRÖNSTED AND JOHN W. WILLIAMS. Polytech. Inst. of Copenhagen. *J. Am. Chem. Soc.* **50**, 1338-43(1928).—The variation of the activity coeff. of a satg. salt with change in the dielec. const. (to 15%) of the solvent is further studied. The activity coeffs. are

detd. from the effect of a solvent salt (NaCl) on the soly. of insol. satg. salts (croceo-tetranitrodiammino cobaltiate and luteo-tetranitrodiammino cobaltiate); the dielec. consts. are varied by adding Et_2O or sugar, in varying amts., to H_2O . A plot is made of the values of the soly. ratio $\log s/s_0$ (obtained from expt) against the sq. roots of the ionic strength for various mixts. and the slopes of the resulting straight lines detd. The change produced in the slope by change in the solvent agrees with that required by the Debye and Hückel interionic-attraction theory.

J. BALOZIAN

Solubilities and molecular weight determinations in liquid chlorine. K. H. BUTLER, M. A. MCINTOSH AND D. MCINTOSH. Dalhousie Univ., Halifax, N. S. *Proc. Trans. Nova Scotian Inst. Sci.* 16, 198 (1926); cf. *C. A.* 22, 2087. Fifty-nine of the commoner salts are insol in liquid Cl_2 at its b. p. S, As lumps, Ag, Cu and Zn do not react; Al is changed quickly into AlCl_3 , which is insol; I, P and Sn react violently, but only in the last case does the b. p. rise, showing that soln is taking place. The ebullioscopic consts. measured were: CHCl_3 , 1.75; CCl_4 , 1.76; SnCl_4 , 1.72; POCl_3 , 1.59; SCl_2 , 1.55; Br_2 , 2.83-2.70.

A. L. HENNE

Liquid hydrogen sulfide as an ionizing medium. H. RITCHIE CHIPMAN AND D. MCINTOSH. Dalhousie Univ., Halifax, N. S. *Proc. Trans. Nova Scotian Inst. Sci.* 16, 189-96 (1928). An app. has been constructed to measure the cond. of substances in liquid H_2S , and a satisfactory method of stirring the soln. has been obtained by blowing puffs of cold air through the liquid. The cond. of 15 substances has been examd. I, triisobutylamine, tripropylamine and SbCl_3 possess an appreciable cond., which was measured over a considerable concn. range. All these substances act as if they were forming complex compds. with the solvent, with the exception of I, which conducts the current like an electrolyte in aq. soln. Conclusion. The cond. of the solns. of the amines and SbCl_3 is due to the dissoen. of a compd. formed with H_2S , while with I, it is due to the dissoen. of I into pos. and neg. ions.

A. L. HENNE

Affinity between asymmetric ions. II. S. W. BERGMAN. *Arkiv. Kem. Mineral. Geol.* 9, No. 42, 11 pp. The assumption previously made by B. (*Ibid.* No. 34) that the difference observed in the soly. of diastereomeric salts depends on the content of energy in the crystals, was established in the present work. In view of the theories of Fajans (*C. A.* 14, 682) and the work of Butler (*C. A.* 19, 764) and Flatt (*C. A.* 17, 3122), according to which soly. depends on crystal energy and ion hydration, it was assumed that the ions of 2 diastereomeric salts yield the same hydration work on dissolving. The difference in the solubilities of these salts then depends on the ionization work only; i. e., the potential lattice energy cannot be the same for 2 diastereomeric salts. B. further assumes that the ionization work of complicated ions is detd. by laws which are similar to those of the simple lattice types and that the ionization work of diastereomeric salts, therefore, may be expressed by the formula $Q = k\sqrt{s/M}$, which corresponds to that advanced by Born and Lande for simple salt lattices (cf. *C. A.* 13, 1557). Q is the ionization work, s the sp. gr., M the mol. wt. and k a const. By considering the case where a racemic acid is decomposed with an optical active base, the equation $P_l - P_d = K(\sqrt{s_d} - \sqrt{s_l})$ is derived, in which P_l and P_d are positive, increasing functions of the soly. of the l - and d - salt, resp., $K = k/\sqrt{M}$, and k is considered the same for both salts, and s_l and s_d are the sp. grs. of the l - salt and d -salt, resp. In detg. the sp. gr. and soly. of a series of diastereomeric salts it was found that of 2 diastereomeric salts the one possessing the highest soly. had the lowest sp. gr., which thus fulfills the above equation. The mechanism of the decompn. could therefore be comprehended as follows: In a soln. of a racemic acid and an optically active base 2 isomeric salts may be formed. The configuration of the ions requires (because of the arrangement of the charges) more densely constructed crystal lattice in one salt than in the other. The densest salt possesses a higher potential electrostatic energy and in dissolving it more work must therefore be produced than in dissolving its isomer. When the energy at disposal, the hydration energy of the ions, is to be considered the same for both salts, the soly. of the sp. heavier salt will be less than that of the lighter. The expts. which are described in detail were carried out with the d - and l -tartrates and mandelates of cinchonine, quinine, strychnine and brucine. A modification of Pasteur's decompn. method is described.

D. THUSEN

Substances changing color in the presence of neutral salts, and the constitution of a series of indicators of graduated indices which allow the comparison of salt solutions. FRED VLÄS, PAUL REISS AND MADELEINE GEX. *Compt. rend.* 185, 1127-30 (1927); cf. *C. A.* 22, 1719. The color changes of a series of 12 dyes have been studied with solns. of KCl , LiCl , NaCl , BaCl_2 , CdCl_2 , SeCl_4 , KOAc , NH_4Cl , K_2SO_4 , and $\text{Hg}(\text{CN})_2$ of various concns. A concn. of 0.0001 N of BaCl_2 or SrCl_2 visibly changes the color of

sulfonecyanine. The following relation has been found to be valid: $p\mu = pM_0 - pX_{1/2}$, where $p\mu$ is the relative massivity of the salts to a standard, $pX_{1/2}$ is the neg. log of the salt concn., and pM_0 that for KI with the same dye. J. H. PERRY

Further experimental results on the dependence of electrolytic conductance upon the field strength. M. WIEN *Physik. Z.* **28**, 834-6(1927); cf. *C. A.* **22**, 906. In fields of high potential gradient, the cond. of electrolytes is increased. This increase $\Delta\lambda$ is occasioned not only by the heating effect of the current which causes an increase $\Delta\lambda_h$ but also by a voltage effect $\Delta\lambda_v$, $\Delta\lambda = \Delta\lambda_h + \Delta\lambda_v$. $\Delta\lambda_v$ increases markedly with the valence of the ions and with the voltage. The values of $\Delta\lambda_v$ were detd. for aq. solns. of the salts $K_3Fe(CN)_6$, $CeCl_3$, $K_4Fe(CN)_6$, $MgSO_4$, $CuSO_4$, $Al_2(SO_4)_3$, $Ca_3[Fe(CN)_6]_2$ and $Ba_3[Fe(CN)_6]_2$ at concns. of 0.001, 0.002, 0.004, 0.008 and 0.016. It was found that $\Delta\lambda_v$ decreases with the concn. Acetone solns. of $Ca(NO_3)_2$, $NaCl$, $CoCl_2$, CdI_2 and KI were also investigated. As in the case of aq. solns., $\Delta\lambda_v$ increased with the valence of the ions but was about 4 times greater in acetone than in water for ions of the same valence because of the smaller dielec. const. of acetone. E. R. S.

A study of the activity of cadmium-iodide in aqueous solution. FREDERICK H. GETMAN *J. Phys. Chem.* **32**, 940-6(1928). The activity of CdI_2 has been obtained from 13 to 0.005 *M* solns. by e. m. f. measurements. $CdBr_2$ lies approx. midway between $CdCl_2$ and CdI_2 with respect to activity coeffs. R. H. LAMBERT

Activity coefficients of hydrogen chloride in ethyl alcohol. J. W. WOOLCOCK AND H. HARTLEY *Phil. Mag.* [7], **5**, 1133-44(1928). The activity coeffs. of solns. of HCl in C_2H_5OH have been obtained by measurements of the electromotive force of the cell $H_2|HCl|AgCl|Ag$ at 25°. A comparison has been made with the results obtained by Danner (*C. A.* **17**, 664) and by Harned and Fiesher (*C. A.* **19**, 923). The equation $-\log f = 3.40 C^{1/2}$ has been found to represent the course of the activity coeff. in the range 0.0003 *M* to 0.004 *M*, the value of the coeff. being greater than that demanded by the Debye theory. It is suggested that this is due to incomplete dissociation. G. G.

Electroösmosis and the effect of anions. A. RABINERSON *Koll. id. Z.* **45**, 122-9(1928).—With a diaphragm of talcum, R. measured the amts. of water transported electrically for HCl , H_2SO_4 , citric acid, $NaCl$, Na_2SO_4 , Na citrate, $BaCl_2$, and $FeCl_3$ solns. for concns. of 0.5 to 40 millimols. The max. water transported occurs at a concn. of 2 to 5 millimolal, which is a higher concn. than expts. with single capillaries require. The order of the effect on the water transport is $Cl < SO_4 < citrate$ for anions, for cations $Fe < H < Ba < Na$. Expts. with mixed electrolytes were made to study the competitive action of anions. Sulfate and citrate raised the concn. of $FeCl_3$ and $Th(NO_3)_4$ necessary to give the max. water transport while Cl and NO_3 had no effect. M. D.

Lecture experiments on the hydrogen-ion concentration changes in the rusting of iron. W. R. G. ATKINS *Marine Biol. Lab., Plymouth, Eng. Nature* **121**, 615(1928).—In the rusting of Fe a trace of acid must be present. The Fe^{II} salt is first formed, and this on oxidation to the Fe^{III} salt regenerates the acid, because of the larger degree of hydrolysis. Expts. demonstrating the course of the reaction are described. Bromophenol blue (0.04%) gives an acid reaction ($p_H < 3.2$) in a dil. soln. of a Fe^{III} salt. $FeSO_4$ soln. gives a purple color, indicating no greater acidity than p_H 4.2. On standing, the latter is oxidized, resulting in an increased acidity of the soln., as shown by the indicator. The reaction may be made instantaneous by adding a dil. H_2O_2 soln. (p_H 5.6). The action of CO_2 in soln. may be shown with a bright Fe wire in distd. H_2O contg. bromothymol blue (0.04%). A trace of $NaHCO_3$ is first added to bring the p_H to 6.7 (yellow-green). On standing, the Fe is attacked by the H_2CO_3 present, and the soln. becomes less acid, particularly around the wire. The color changes may be projected on a screen. When the initial soln. has a higher acidity, the rate is slower, indicating that it is the $Fe(OH)_2$ resulting from hydrolysis, which is oxidized. The reaction also proceeds slowly with slightly alk. solns. With 0.02% phenol red, an alk. reaction ($p_H = 8$) is finally obtained, and also with xylenol blue ($p_H = 8.4-8.6$). Fe wire standing in a tube of distd. H_2O causes a continuous absorption of CO_2 , and when the acid is set free by adding H_2O_2 soln. as above, the resulting p_H is about 4.6, showing that the soln. is nearly satd. with CO_2 . F. A. JENKINS

Selective permeability of membranes. Influence of the ion mobility on the polarization. M. L. E. CHOUROVSK. *Compt. rend.* **186**, 1548-51(1928); cf. *C. A.* **21**, 3791.—If 2 solns. of an electrolyte are unequally concd. and sep'd by a "charged" membrane, the membrane becomes polarized only when the ion carrying the same charge has a mobility equal to or greater than the mobility of the ion with the opposite charge. $K_3Fe(CN)_6$ verifies this assumption. A. L. HENNE

The region of existence of unimolecular reactions. LOUIS S. KASSAL, Calif.

Inst. Tech. *J. Am. Chem. Soc.* **50**, 1344-52(1928).—The decompn. of polyat. mols. is bimol. at high pressures (there is also present a negligible unimol. portion) and is due to collisions. As the pressure is lowered the unimol. part becomes dominant obscuring the bimol., the principal factor being the spontaneous decompn. of the activated mols. At still lower pressures the rate of the unimol. part decreases until the reaction becomes sec.-order, nearly all the activating mols. decompg. and collisions becoming infrequent. The const. for the low-pressure sec.-order reaction exceeds that of the high-pressure and may be greater by a factor of millions for complex mols. Dushman's formula for unimol.-reaction rates is in disagreement with exptl. data. That all unimol.-reaction rates are the same for temps. where E_0/RT is the same is only roughly correct. J. B.

Reaction velocity at a liquid-liquid interface. RONALD PERCY BELL. *J. Phys. Chem.* **32**, 882-93(1928). The velocity of the oxidation of benzo-*o*-toluidide to benzovanthranilic acid by neutral KMnO_4 was studied at the water-benzene interface of the 2-phase system. After a short initial stage the reaction rate is independent of rate of stirring, within limits. For concns. of benzo-*o*-toluidide in benzene of 5-6 g. per l. the reaction velocity is independent of concn. The interfacial tension between the benzene and H_2O layers was measured by the drop-wt. method. Results obtained bear out the hypothesis that permanganate ions striking an adsorbed layer of benzo-*o*-toluidide and diffusion from one solvent to the other is not an important factor. Studies of thermal activation gives inconclusive results. R. H. LAMBERT

Method of generalizing the law of mass action for heterogeneous surface reactions. F. HERN CONSTABLE. *Proc. Cambridge Phil. Soc.* **24**, 307-14(1928). To the conditions of reaction in homogeneous systems is added the condition that adsorption of the reactant occurs on the centers of activity of the surface. The surface is treated as if it were homogeneous, reaction taking place as if those centers on which the heat of activation is smallest were alone responsible for chem. change. The general equation is obtained in terms of the rate of bombardment and the mean lives of the mols. on the surface. The same areas assoc. with the forward reaction must also catalyze the backward reaction. Since a general solution is impracticable, only special cases of irreversible syntheses and decompn. are considered. JAMES M. BELL

Studies in homogeneous gas reactions. II. Introduction of quantum theory. LOUIS S. KASSEL. *J. Phys. Chem.* **32**, 1065-79(1928). K.'s theory of unimol. reactions (*C. A.* **22**, 1517) is extended by the introduction of quantized degrees of freedom. The cases of quantum oscillators of a single frequency and of 2 frequencies whose quotient is an integer are worked out and the methods for more complex cases are indicated. There is no longer any difficulty in accounting for the rate of decompn. of N_2O_5 at moderately high pressures. The theory does not account for the complete maintenance of the rate at low pressures, but the discrepancy is not large. Several ways of overcoming this difficulty are discussed. For azomethane the results may be completely accounted for by assuming oscillators in such numbers and of such frequencies as to give reasonable values to the mol. heat and the internal energy. With these assumptions the necessary diam. for collisional deactivation is of the order of magnitude of kinetic theory diams. JAMES M. BELL

Influence of the oxygen atom of the ring on the reaction velocity of several lactones. ELIAS HOLLO. Univ. Turku, Suomi, Finland. *Ber.* **61B**, 895-906(1928).—The prepn. of $\text{OCH}_2\text{CH}_2\text{OCOCH}_3$, $\text{OCH}_2\text{CH}_2\text{OCOCHMe}$, $\text{OCH}_2\text{CH}_2\text{OCOCHEt}$, $\text{OCH}_2\text{CH}_2\text{OCOCHMe}_2$, $\text{CH}_3\text{CH}_2\text{CH}_2\text{OCOCH}_2$ and $\text{CH}_3\text{CH}_2\text{CH}_2\text{OCOCHMe}$ has been

greatly improved. Their hydrolysis and lactonization velocities have been detd. in acid $\text{H}_2\text{O} + \text{Me}_2\text{CO}$ soln. at 25° . The presence of an alkyl group in the α -position retards the reactions; the hydrolysis is more affected than the lactonization. The order of magnitude of the phenomenon is $\text{Me} < \text{Et} < \text{Me}_2$. If 100 represents the reaction velocity of the simpler δ lactone, it may be assumed that the O of the ring diminishes by 56-57% the hydrolysis velocity and by 39-41% the lactonization velocity. A. L. H.

Reaction regions. XVIII. Velocity of propagation of the reaction in iron-sulfur mixtures. W. P. JORISSSEN AND C. GROENEVELD. *Rec. trav. chim.* **47**, 737-42(1928).—The velocity of propagation of the reaction Fe-S is measured in a quartz tube 10 mm. in diam., and 11 cm. long, on mixts. contg. 50 to 90% Fe. The velocity is at a max. around 75% Fe. **XIX. Reaction regions in which one of the substances is guncotton.** W. P. JORISSSEN AND H. A. STARINK. *Ibid.* 743-51.—Binary and ternary mixts., 1 component of which was guncotton (12.12% N) contg. various proportions of the constituents were prepd. and their ability to react was tested. The time of reaction was measured in the gelatinized mixts.; it varies with % guncotton. The mixts. can be

gelatinized without difficulty, except when the compn. approaches the limit of reactivity.

G. CALINGAERT

Equilibrium in solutions. A note on "The Activity Theory of Reaction Velocity." W. F. KENRICK WYNNE-JONES. *J. Chem. Soc.* **1928**, 1230-3, cf. *C. A.* **22**, 1263 and following abstract. An evaluation of Soper's equations connecting the activity coeff. with the ionic strength for aq. solns. at 25°. Bronsted's formula is considered entirely satisfactory when applied in the region of dil. solns.

J. S. REICHERT

Equilibrium in electrolyte solutions and the reaction velocity equations. FREDERICK G. SOPER. *J. Chem. Soc.* **1928**, 1233-5 (1928), cf. preceding abstract. A reply.

J. S. REICHERT

Present position of the theory of centers of activity in heterogeneous catalysis. F. HURN CONSTABLE. *Proc. Cambridge Phil. Soc.* **24**, 291-306 (1928). From this summary C. concludes that there is evidence from many diverse branches of science showing that catalysis is due to the action of strong sp. fields of force that emanate from special configurations of atoms upon the catalyst surface, and that the main outlines of the exptl. facts dealing with adsorption and catalysis can be explained quantitatively by this means.

JAMES M. BELL

Oxidation of unsaturated hydrocarbons by free oxygen in presence of catalyzers. S. S. MEDVEDEV AND E. N. ALEKSEYEV. *Papers Karbov. Khim. Inst. Bach. Memorial Vol.* **1927**, 110-27. Investigations of Willstätter and Sonnenfeld (*C. A.* **9**, 308) having shown that a soln. of cyclohexene in presence of Os and in an atm. of O rapidly absorbs the latter and furnishes oxidation products, an investigation was made of the catalytic action of Os moderated by the presence of less active substances on the process of oxidation of cyclohexene and Δ^2 -methylcyclohexene. The catalyzers used were OsO₄ deposited (1) on fibrous asbestos, (2) on Al₂O₃, (3) on FeO, (4) on Mn₂O₃, (5) on CuO. The first named was the most active, whereas the activity of the last named was very small. The difference in the effects of these catalyzers is apparently chiefly due to interaction of unknown nature between OsO₄ and the catalytically less active oxides of other metals. The character of the oxidation process depends very much on the nature of the solvent used for the hydrocarbon. Contrary to the statement by Willstätter and Sonnenfeld that benzene is not a suitable solvent, whereas with acetone there is an energetic O-absorption, the absorption of O is more energetic with benzene as solvent than with acetone. With oxidation of cyclohexene in the presence of Os deposited on asbestos as catalyzer and benzene as solvent, the following products are obtained: Δ^2 -cyclohexenol, an unknown aldehyde, adipic acid and some unknown substances in the form of peroxides. With acetone taken as solvent the products of reaction are apparently different.

BERNARD NELSON

Behavior of aluminum triethyl with nickel catalyst at high temperatures. A. MÜLLER AND A. SAUERWALD. *Monatsh.* **48**, 757-9 (1927). AlEt₃ is not affected by Ni-black I (Zelinski, cf. *C. A.* **19**, 3053) in presence of H₂.

Mechanism of hydrogen-ion catalysis. ERICH MÜLLER. *Z. physik. Chem.* **134**, 190-2 (1928).—An explanation is given of esterification of an alc. by an acid involving complex addn. compds. with the H⁺ ion.

M. R. FENSKE

Changes of inter-atomic energy according to thermodynamics and catalytic action. R. D. KLEEMAN. *Phil. Mag.* [7], **5**, 1191-8 (1928), cf. *C. A.* **22**, 1888. Mathematical. The kinetic energy of a mol. is not exactly proportional to the temp., but also depends on the vol. of the gas, especially when it is large. A substance may permanently change the internal energy of another substance by contact when both are in the perfectly gaseous state. When the substances are not in the perfectly gaseous state, the effect is likely to be much more pronounced. Since a change in the internal energy of an atom must be accompanied by a change of its nature, it follows that the nature of matter is constantly changing, these changes being, however, as far as is known, immeasurably small, at least in most cases. An atom would accordingly bear the impression of all of its previous history. Contact catalytic action, when the catalyst does not change, is shown to be a consequence of the laws of thermodynamics.

GEORGE GLOCKLER

Application of an electromagnet force to "thermobalance." ZEN-ICHI SHIHATA AND MASAJI FUKUSHIMA. Tohoku Imp. Univ., Sendai. *Bull. Chem. Soc. Japan* **3**, 118-23 (1928). Honda's thermobalance (cf. *C. A.* **9**, 2610) has the following defects: by magnifying the sensitiveness of the balance, the movements on its scale are multiplied even by a small change of weight, and hence it is necessary to interrupt the measurement and change its weight on the beam of the balance during an expt.; during this manipulation, the change in the weight of a sample cannot be measured, as the up and down movements of the arms of the balance cause the spring to stretch and contract, the hysteresis of the spring causes an error; the thermocouple cannot be fixed with the

sample, so that when the position of the latter is displaced by the change of its weight, it recedes from the former and the exact reacting temp. is not observable by the thermocouple. To remedy these drawbacks, an electromagnet is attached to one side of the beam; the current is adjusted in the observing position so that the scale is always set at the zero point. The change in the wt. of the sample can be indirectly found from the amt. of current, the sensitiveness can be magnified, the hysteresis eliminated, and the reaction temp. is read correctly. The sensitiveness compares favorably with that of the chem. balance. In order to verify the accuracy, the decomn. curves of the following pure compds. have been detd.: CaCO_3 , CuSO_4 , CdSO_4 , BaCl_2 and Mohr salt.

A. L. HENNE

Newton's law for the emission of heat in carbon dioxide. SYBIL MARSHALL. *Proc. Phys. Soc.* **39**, 429-34(1927); *Science Abstracts* **31**, A38. This paper is an extension of the investigation, started by M. and Vick (cf. *Proc. Phys. Soc.* **37**, 312-21(1925)), of the justification of employing Newton's law of cooling when estg. the external heat loss from the surface of a solid in a gaseous medium. In this case, the loss in a vertical system, contg. in turn CO_2 , O and N, was examd., the app. consisting of compensated Pt wires mounted along the axis of ice-water-cooled glass tubes and connected to the terminals of a Callendar Griffiths bridge. The results show that, for tubes between 1 cm. and 3 cm. diam., the law is applicable only as far as 10° for pressures between 1 atm. and 6 cm. Hg. The deviation above this temp. depends on the width of the tube and the d. of the gas, being greater for CO_2 than for O or N.

H. G.

Development of a method of radiation calorimetry and the heat of fusion or of transition of certain substances. LUKE E. STEINER AND JOHN JOHNSTON. *J. Phys. Chem.* **32**, 912-39(1928). Time temp. curves of cooling and heating are discussed with respect to their interpretation. A special radiation calorimeter is described in which a Dewar flask is used together with thermocouple regulation. Heating and cooling curves agree for *m*-dinitrobenzene. Heats of fusion obtained in cal. per mol. were: phenol, 2690 and benzophenone, 4600. Heats of transition of the various modifications of NH_4NO_3 and HgI_2 were also obtained as follows: orthorhombic to tetragonal NH_4NO_3 , 310 and tetragonal to isometric, 980, red to yellow HgI_2 , 640 cal. per mol.

R. H. L.

The heat of vaporization at zero absolute. J. E. VERSCHAFFELT. Univ. Ghent, Belgium. *J. chim. phys.* **25**, 408-9(1928). Criticism of Kolosovskii (*C. A.* **22**, 1069, 2000). K.'s argument is based on obviously erroneous mathematical discussions. None of its conclusions has been demonstrated.

A. L. HENNE

The free energy and fugacity in gaseous mixtures of hydrogen and nitrogen. ALBERT R. MERZ AND COLIN W. WHITTAKER. U. S. Bur. Chem. and Soils. *J. Am. Chem. Soc.* **50**, 1522-6(1928). The molal vols. of H_2 - N_2 mixts. as well as the partial molal vols. and free energies of the individual gases are tabulated. Max. deviations from a perfect soln. do not exceed approx. 20%, even at 1000 atms.

ALBERT R. MERZ

Critique of the electric differential method for measuring C_p in gases. II. The experimental deviation from the principles of the C_p determination. The obtainable accuracy of C_p . MAX TRAUTZ AND OTTO TRAUTZ. *Phys. Inst. Leipzig. Ann. Physik* **86**, 1-65(1928), cf. *C. A.* **21**, 3534. A discussion of the exptl. errors and their corrections. The exptl. procedure is described. The following improved values of C_p have been obtained: air, 4.98; N_2 , 4.99; O₂, 4.99; CO_2 , 6.89; H_2 , 4.87; CH_4 , 6.52; C_2H_6 , 5.55; AcOEt , 5.8; Me_2CO , 6.3; A, 3.07.

A. L. HENNE

Contribution to the theory of the specific heat C_v of monatomic fluids at high temperature. A. EUCKEN AND H. SEEKAMP. *Z. physik. Chem.* **134**, 781-89(1928).—The assumption has been made that the atoms are surrounded by an elastic shell, and that the energy of shock of the atoms may be calcd. as an exponential function of the distance between atoms. On the basis of this hypothesis, E. and S. attempt to calc. the decrease in sp. heat of liquid A with increase in temp. The calcns. do not agree very closely with the exptl. data, giving only a qual. confirmation of the hypothesis.

G. CALINGAERT

The specific heat of solid substances at low temperatures. K. CLUSIUS AND P. HARTECK. *Z. physik. Chem.* **134**, 243-63(1928).—C. and H. measure the sp. heats of Au, Ga, Zn, CuO , ZnO , Ag, Cl and NH_4 carbamate from 200° down to about 15° abs. Only the exptl. data are reported, and the discussion will be published later.

G. CALINGAERT

New measurement of the heat conductivity of solid crystalline substances at 0° and --100°. A. EUCKEN AND G. HUHN. *Z. physik. Chem.* **134**, 193-219(1928).—E. and K. measure the heat cond. at 0° and --100° of 55 cryst. substances or mixts. of cryst. substances, comprising alkali halides and some common salts and minerals. The effect of particle size on cond., as expressed by Eucken and Neumann (*Z. tech. Physik.* **6**,

691(1925); cf. *C. A.* 19, 1086) is apparent only in feldspar, and not in crystals of high symmetry. It is also apparent in mixts. of crystals. The formation of mixed crystals lowers considerably the cond. and its neg. temp. coeff. The influence of impurities can be expressed also by the law of Matthiessen for the elec. cond. of metals contg. impurities. In the alkali halide series, the cond. is maximum when the masses of the 2 atoms are approx. equal. Within series of compds. of closely related structure, the hardness parallels the cond. The data in general corroborate Debye's theory, but cannot be reconciled with his more specialized equations. G. CALINGAERT

Thermodynamics of dispersed systems. A. MARCH. *Ann. Physik* 84, 605-23 (1927).—From a thermodynamic analysis of dispersed systems it is shown that for particles of radius less than 10^{-7} cm. the degree of dispersion decreases with increasing concn. and increases with rise of temp., and that the conditions governing the stability of such systems are not to be sought in the thermal agitation or in the elec. charge of the particles. B. C. A.

Null point [absolute zero] state. W. JAZYNA. *Physik Z.* 28, 908-11 (1927). Theoretical. The thermodynamical implications of a distinction between the "quasi-permanent" equil. state, corresponding with the expression $(Q_2/Q_1 = T_2/T_1)$, and the "permanent" equil. state corresponding with $(Q_1 = ST)$ are discussed. B. C. A.

The electrostatic explanation of complex formation. A. E. VAN ARKEL AND J. H. DE BOER. *Rec. trav. chim.* 47, 593-605 (1928). A discussion is given of the literature on complex-compd. formation. The Born lattice theory is of great importance together with polarity considerations for explaining complex formation. Ions of a nearby series of the periodic system and complex-ion building and crystal structure may be explained by this fact. Mols. may enhance complexity by proximity to ions. Energy considerations are given in the form of formulas. The formation of $\text{Ag} + \text{NH}_3$ and of hydrated Ag is calcd. both when polar and non-polar. Three forms of complex ions are considered, i. e., ions on ions, dipole mols. on ions and non polar mols. on ions. R. H. L.

Behavior of dilute electrolytes in strong fields. M. BLUMENTRITT. *Ann. Physik* 85, 812-30 (1928).—The deviation from Ohm's law with strong external fields is studied mathematically and the increase in cond. with an increase in the external field x is given by the expression: $\Delta\eta = Ax^2(1 - \beta x^2)$. The increase for low field strength is given by the first member of the equation Ax^2 and the const. A is found to be proportional to

$\frac{1}{\sqrt{D}\eta} g(z)$, in which η is the equiv. concn. per l., z is the valency, D the dielec. const., and for binary electrolytes with ions of equal friction const. $g(z) = z^{3.6}$. The initial rise in cond. increases with decreasing concn. and dielec. const. inversely proportional to the square root of the concn. and D . The 2nd member of the equation βx^2 produces a decrease in the initial rise in cond. and β is found to be proportional to $\frac{D}{\eta} f(z)$, in which

$f(z) = z$ for binary electrolytes with ions of equal friction const. Values of A obtained by calcn. for various electrolytes agree well with those experimentally obtained by Wien for electrolytes in which the valency relations are 2-2, 2-3 and 2-4, but where these relations are 1-3 and 1-4 large differences occur. Thus for $\text{K}_3\text{Fe}(\text{CN})_6$ with $x = 0.0005$, $A \cdot 10^{11}$ is 1.7 as calcd. and 0.44 as observed, while with $\text{K}_4\text{Fe}(\text{CN})_6$ with $x = 0.0005$, $A \cdot 10^{11}$ is 4.4 as calcd. and 0.88 as observed. Conclusion: The Debye-Huckel theory is no longer applicable to these cases. H. STOERTZ

Effect of tension upon the conductivity of electrolytes in weak fields. MAX WIEN. *Ann. Physik* 85, 795-811 (1928).—The resistance of electrolytes deviates from Ohm's law when the flow consists of short current impulses under high tension. This deviation is affected by the intensity of the field, and W. has studied this effect for weak fields of the order of 3000 to 30,000 v./cm., in solus. contg. ions in which the valency relations are 1-2, 1-3, 1-4 and 2-2. In all the solns. investigated the effect of tension is given by the expression: $\Delta\eta_s = Ax^2(1 - \beta x^2)$, in which $\Delta\eta_s$ is the so-called "tension effect," A and β are consts., and x is the external field in v./cm. A is found to be approx. proportional to the square of the product of the valencies of the ions involved ($z_1 z_2$), and inversely proportional to the square root of the cond., as indicated by the formula: $A = 5.5 z_1 z_2 \sqrt{\kappa_0} \times 10^{-11}$, in which κ_0 is the cond. $\times 1/1000$. Values of $A \cdot 10^{11}$ are given for various values of x as follows: for $\text{K}_3\text{Fe}(\text{CN})_6$ with $x = 0.001 - 0.40$, with $x = 0.0005 - 0.44$, with $x = 0.00125 - 0.77$; for $\text{Li}_3\text{Fe}(\text{CN})_6$ with the 3 values of x above, 0.51, 0.68, 0.96; for $\text{K}_4\text{Fe}(\text{CN})_6$ with the 3 values of x above, 0.66, 0.88 (0.82); for $\text{Li}_4\text{Fe}(\text{CN})_6$, 0.91, 1.57, (1.64); for MgSO_4 , 1.11, 1.49, 2.5; for MgCrO_4 , 1.02, 1.21, 1.8; for $\text{Mg}_3(\text{Fe}(\text{CN})_6)_2$, 2.3, 3.3, 4.6; for $\text{Ba}_3(\text{Fe}(\text{CN})_6)_2$, 2.6, 3.9, 5.6; for $\text{Be}_3\text{Fe}(\text{CN})_6$, 3.6, 6.0, (12.4); for $\text{Mg}_2\text{Fe}(\text{CN})_4$, 3.8, 5.8 (12.0); for $\text{Ba}_2\text{Fe}(\text{CN})_4$, 4.2, 5.0 (11.6).

The const. β also increases with the product Z_1Z_2 and decreases with the concn. or cond. Values of β for the values of x given above are as follows: for $K_3Fe(CN)_6$, 1.7, 1.1, 3.4 for $Li_3Fe(CN)_6$, 2.1, 2.3, 3.8; for $K_4Fe(CN)_6$, 1.7, 1.7 (3.8); for $Li_4Fe(CN)_6$, 1.5, 2.1, (3.8); for $MgSO_4$, 1.7, 1.7, 6.0; for $MgCrO_4$, 2.4, 3.0, 7.5; for $Mg_3(Fe(CN)_6)_2$, 1.9; 2.1, 4.5; for $Be_2Fe(CN)_6$, 2.5, 3.1 (4.0); for $Ba_2Fe(CN)_6$, 1.9, 3.2 (6.9). In acetone, A is greater and β smaller than in H_2O solns. Thus for $CoCl_2$ in acetone, with $x = 0.0002$, $A = 1.1$ and $\beta = 0.6$.

H. STOERTZ

Dipolar moment of symmetrical compounds and cis-trans isomerism with simple linkages. ARNOLD WEISSBERGER. *Physik. Z.* 29, 272-3(1928).—The fact that some symmetrical compds. are dipolar could possibly be explained by a constitution similar to the cis-trans isomerism; this constitution would be rendered stable by residual valencies. Another explanation would be a deformation of the C tetrahedron into a pyramid. Not much argument is given to support these assumptions. A. L. H.

The electric moment and the spatial disposition of the atoms of a few p -derivatives of benzene. JOHN W. WILLIAMS. *Physik. Z.* 29, 271-2(1928).—The elec. moment of several derivs. of C_6H_6 has been measured in electrostatic multiplied by 10^{-18} units: p -xylene, <0.1 ; p -dichlorobenzene, 0; p -dinitrobenzene, <0.3 ; hydroquinone diethyl ether, 1.7; hydroquinone diacetate, 2.2. Conclusion: The oxygenated groups of the 2 last compds. are not located on a straight line.

A. L. HENNE

Decomposition of carbon monoxide in the corona due to alternating electric fields. ERWIN OTT. *J. Chem. Soc.* 1928, 1378; cf. *C. A.* 19, 1999; 21, 2436.—O. disagrees with Lunt and Venkateswaran, who give the formula $C_3O_{2.5}xH_2O$ for the brown solid formed in the decompn. of CO in the corona. Based on definite evidence of the production of unimol. CO in the gases leaving the Siemens ozonizer, the equation of the decompn. is: $4CO = C_3O_2 + CO_2$ and the brown solid is the product of polymerization of gaseous C_3O_2 .

H. STOERTZ

Measurement of the displacement of negative carriers in flames. ERICH MARX AND PAUL KAPPLER. *Physik. Z.* 29, 261-9(1928).—M. and K. atomize alk. salts in flames and measure the velocities of the neg. carriers. They find that $\bar{K}_2 \sim \sqrt{1/\text{concn.}} + \text{const.}$ K_2 : (velocity in $\frac{\text{cm.}}{\text{sec.}} / \frac{\text{volt}}{\text{cm.}}$) is 1500-1800 for Li, 1000-1200 for Na, 800-1000 for K, 500-700 for Rb and about 2000 in the pure flame.

A. L. HENNE

The ratio of the electric units of charge. GEORGE C. LAWRENCE. Dalhousie Univ., Halifax, Nova Scotia. *Proc. Trans. Nova Scotian Inst. Sci.* 16, 183-9(1928).—Essentially a duplication of Rosa and Dorsey's work (*C. A.* 2, 500). The capacity of a cylindrical condenser, calcd. in e. s. u. from its dimensions, was compared with its capacity in electromagnetic units measured in a Maxwell bridge. A value of $2.9963 \times 10 \pm 0.05\%$ was obtained which agrees with the value of R. and D. Several simplified devices are described.

A. L. HENNE

The electrical conductivity of calcite. W. J. JACKSON. Dalhousie Univ., Halifax, N. S. *Proc. Trans. Nova Scotian Inst. Sci.* 16, 46-53(1928).—In calcite crystal, there is a polarization effect possibly due to a space charge near the electrodes or throughout the crystal. There is a displacement current as well as a conduction current. The relation between the current and the temp. is approx. exponential. The cond. is directional. An exposure of the crystal to x-rays increases the cond.; the return to a normal value is completed within 1 or 2 hrs.

A. L. HENNE

Visual method of showing the high-temperature coefficient of resistance of metals as compared with alloys. PAUL ROOD. *J. Optical Soc. Am.* 16, 357-9(1928).—A diagram of a circuit is given in which the grid potential on a UX201A tube is controlled by the voltage across the terminals of a short section of wire. This gives essentially grid amplification. The large increase in resistance due to rise in temp. when a metal such as Fe, Cu or Al is used is shown by an increase in plate current as read by the milliammeter. However, when an alloy of low temp. coeff. of resistance is used, the plate current remains almost const. regardless of the temp. of the wire. W. W. S.

New method of conductivity measurement by means of an oscillating valve circuit. E. F. BURTON AND A. PITT. *Phil. Mag.* [7] 5, 939-43(1928).—A primary valve oscillating circuit and subsidiary measuring circuit have been developed which enable one to obtain remarkable indications of the conductivities of very dil. aq. solns. and of various org. liquids.

GEORGE GLOCKLER

Construction of a valve oscillator for use in conductivity measurements. J. W. WOOLCOCK AND D. M. MURRAY-RUST. *Phil. Mag.* [7], 5, 1130-3(1928).—A valve oscillator similar to that described by Ulich (*C. A.* 19, 2904) has been constructed and applied to the measurement of the cond. of dil. solns. of acid and salts in non-aq. solvents. Ex-

cellent minima are obtained even with resistances as high as 100,000 ohms, provided that not only the resistances but also the capacities in the bridge circuit are accurately balanced.

GEORGE GLOCKLER

The diffusion potential and the dissociation of hydrochloric acid. ALFONS BUHL. *Physik. Z.* **28**, 767-70(1927).—The following conclusion has been reached on the basis of the detn. of difference of potential of the chain HgCl₂ soln. 1, air/soln. 2, soln. 1/HgCl. The decrease of cond. of an electrolyte following an increase of concn. is not caused by a decrease of the degree of dissociation, but rather by a reduction of migration velocity of the ions. The latter is therefore not a const. but a function of the concn. E. K.

Theory of passivity. I. Theory of polarization by anodic deposition and passivation of metals. W. J. MÜLLER AND K. KONOPICKY. *Monatsh.* **48**, 711-25(1927), cf. *C. A.* **19**, 1221, **21**, 3536, 3784; **22**, 347. Electrometric investigations of the passivity of certain metals in acid media have led to the conclusion that the observed effects are most readily explained by assuming the existence of a sparingly conducting film on the metal anode. The formation of such a film, which probably consists of metal salt or basic salt, causes a progressive diminution of the effective surface of the electrode and a consequent increase in ϵ d. By postulating the existence of such a film, an equation is derived which represents the variation of current strength with time. The equation in its abbreviated form is $i = C + A[1 - (i_0 - i) + 2.3 i_0 \log[(i_0 - i)(i - i_r)]]$, where t represents the time elapsed, i the current strength after time t , i_0 the original and i_r the residual current strengths. The quantities C and A are functions of various phys. and electrochem. quantities, but may be considered as consts. characteristic of the metal concerned. The equation represents in a very satisfactory manner the behavior of Cu, Ni and Fe in solns. of H₂SO₄. The behavior of Cr is, however, anomalous, the values of A increasing with time. Calculs. of the cond. of the liquid in the pores of the anode sheath show that with Fe and Cu, but not with Ni, the constituent salts are probably the stable hydrated sulfates. During the deposition the potential of the metal does not change, the observed variation in potential being due to the change in resistance consequent on the growth of the deposit. The similarity between the current time curves for Cu, where no passivation occurs, and Fe, which becomes actually passive, shows that passivation is due to a change in the metal and that this change occurs only at the high ϵ d.s. resulting from the deposition. The present data are not sufficiently comprehensive to permit the precise evaluation of the ϵ d. necessary for passivation. Previous values of the order 10 amp./sq. cm. are now held to be too low, the true values being probably 5-7 times as great. B. C. A.

Contribution to the study of the Wiedemann-Franz law. III. A. ECKEN. *Z. physik. Chem.* **134**, 220-9(1928). Grunisen and Goens in a study of the elec. and thermal cond. of metals at low temps. (*C. A.* **21**, 3776) concluded that the Wiedemann-Franz law applies accurately to the whole temp. range only if the true metallic resistivity, and not the insulator resistivity is considered. Their data, however, can be reconciled readily with the equations given by E. (*C. A.* **21**, 1584) if λ_1 is affected by impurities or deformations of the lattice. At low temps. the Wiedemann-Franz law deviates from its normal high-temp. value. It is, however, affected very little at any temp. by impurities or by deformations of the lattice. G. CALINGAERT.

Determination of dielectric constants in intense electric fields. J. MALSCH. *Ann. Physik.* **84**, 841-79(1927). Modifications in the technique of Wien (*Physik. Z.* **23**, 399(1922)) are described which permit of the ready detn. of dielec. consts. of conducting liquids such as water as well as those of good insulators in intense elec. fields. A very full discussion is given of the theory of the method and of the probable accuracy. Measurements on water, glycerol and Et₂O, using heavily damped oscillation at frequencies of the order of 10³ kilocycles, indicate that, within the order of exptl. error, no change can be observed in the dielec. constant with field strength, the max. exst. field strength used was 10⁶ v./cm.⁻¹. The effect of intense fields is discussed at length with reference to Debye's theory, on which, it is shown, an increase of the dielec. const. of from 10 to 20% is to be anticipated in the fields employed. B. C. A.

Magnetic susceptibility of binary liquid systems. N. TRIFONOV. *Ann. inst. anal. physico-chim., Leningrad* **3**, 434-5(1926). *Chem. Zentr.* **1927**, I, 2635. Corrections of a previous article (cf. *C. A.* **20**, 2612). CHCl₃ + Me₂O should read CHCl₃ + Me₂CO. Besides the systems already described, the system CH₂:CHCH₂NCS-PhNMe₂, in which the susceptibility is a linear function of the molar fraction, and the system Me₂CO-CS₂, which shows a curve convex to the compn. axis, were studied. C. C. D.

Magnetic characterization of hydrated ferric oxide. II. E. WRECKIND AND W. ALBRECHT. *Ber.* **60B**, 2230-43(1927); cf. *C. A.* **21**, 526.—It is known that hydrates of Fe₂O₃ are more distinctly magnetic than the anhyd. oxide. The magnetic

susceptibility depends upon the method of prepn. even when the final products do not differ considerably regarding their water contents.

EMIL KLARMANN

Report of the Du Bosq Colorimeter Committee. DAVID WESSON *et al.* *Oil and Fat Ind.* 5, 173-5(1928).—The Du Bosq colorimeter is satisfactory for measuring the relative amts. of the same coloring matter in 2 different liquids, providing they are optically the same. Cottonseed oil contains several different coloring matters. The effects of decompn. of the seed and the various conditions used in refining processes affect the light absorption of the oils, and the characteristics of the color. These differences are made apparent by the colorimeter. The limitations of the human eye and the great differences of hue and brilliancy of different oils being taken into consideration, it seems that any system of numerically recording color differences must allow reasonable tolerances. Although results to date appear discouraging, it is believed that by the aid of a modified Du Bosq instrument a satisfactory practical method of oil colorimetry may yet be developed.

E. SCHERUBEL

Reflection from glass. P. AMY *Rev. d'optique* 6, 305 15(1927); *Science Abstracts* 31A, 14. —A series of tests was carried out on various surfaces of glass, some of which had been recently polished and others not. A parallel beam of light was used, the light being reflected from the surface to be tested and then measured in a photometer. Rayleigh's results on the change of the reflecting power produced by polishing were confirmed. The changes produced by chem. action, when glass was dipped into various solns. were tested. The reflecting power decreased to a min. as the length of time in the soln. was increased, but with further increase of time the reflecting power increased again. Change of the temp. of the soln. produced no effect. The max. effect is obtained by using cleaned surfaces in a soln. of $(\text{NH}_4)_2\text{S}$ diluted with an equal vol. of distd. water. Fresnel's theory shows that the polarization is total for $\tan i = n$, where i is the angle of incidence and n the index of refraction. Chem. treatment of the glass surface did not alter this relation.

H. G.

Molecular scattering of light in solid bodies. II. Dependence of scattered light on temperature. G. LANDSBERG *Z. Physik* 45, 442-8(1927); *Science Abstracts* 31A, 88. The exptl. arrangements were little changed from earlier tests (cf. *C. A.* 22, 2104) but an Osram point light was used. The light scattered by the quartz crystal at different temps. was received on the photographic plate, and for each temp. a series of small spots obtained very close together corresponding to different light intensities. Taking Δ as the depth of blackening of the photographic plate, and i_0 and i the intensities of the light proceeding to the Pulfrich photometer through the unblackened and the blackened parts of the plate, resp., a linear relation was found of the form $\Delta = \log(i_0/i)$. This linear relation is in accordance with theory for mol. scattering. In the case taken 24% of the scattering was due to want of homogeneity in the quartz crystal and the remaining 76% is directly proportional to the abs. temp.

Determination of refractive indices of minerals by Becke's immersion method. V. BILLIET. *Natuurwetensch. Tijds.* 9, 97-103(1927).—An account of the method and of the practical details of manipulation, with a discussion of the theoretical basis.

B. C. A.

Application of the spectrographic and spectrophotometric method to the study of the hydrolysis of some alkaline salts. P. JOB. *Compt. rend.* 186, 1546-8(1928).—J.'s method for studying complex formation (*C. A.* 21, 2230) can be applied to any reaction between 2 substances in soln. provided the absorption spectra of the products differ sufficiently from those of the initial substances. The method permits detn. (accurate within 10%) of hydrolysis consts., $k = (\text{C}_{\text{acid}} \times \text{C}_{\text{base}}) / \text{C}_{\text{salt}}$, for the alk. salts of a (weak) acid; k was studied for salts of various phenols formed by action of NaOH and found to be: phenol, 4.5×10^{-4} (15°); *p*-chlorophenol, 2×10^{-5} (12.5°); *o*-nitrophenol, 1.55×10^{-5} ; *p*-nitrophenol, 1.45×10^{-5} ; *o,p*-dinitrophenol, 1.5×10^{-5} . The reaction of 10^{-3} to 10^{-2} molar K_2CrO_4 with H_2SO_4 was studied and the sol reaction found to be $\text{CrO}_4^{2-} + \text{H}^+ \rightleftharpoons \text{CrO}_4\text{H}^-$ with a disson. const. $K = 7 \times 10^{-5}$ (15°).

A. P. S.

Velocity of sound in liquids at high frequencies by the sonic interferometer. J. C. HUBBARD AND A. L. LOOMIS. *Phil. Mag.* [7], 5, 1177-90(1928).—A new method of measuring the velocity of sound in liquids at high frequencies is described. A circular plate of quartz 2 in. in diam. with plane-parallel faces, is caused to vibrate piezoelectrically at such frequencies that the compressional waves produced by it in a column of liquid are of short length as compared with the diam. of the plate and of the liquid column. Under these conditions it is found that the velocity of sound, measured by resonance, is independent of the materials or dimensions of the vessel contg. the liquid; the method is thus free from the troublesome corrections that have hitherto been neces-

sary in measuring the velocity of sound in tubes by resonance. Sound-velocities are reported for a no. of temps. for H_2O and for Hg and for a no. of concns., each at several temps., of KCl and 2 of NaCl at several temps. are reported. Several thermodynamic coeffs. for H_2O and for Hg have been computed from the results. **GEORGE GLOCKLER**

Ultrasonics. R. W. BOYLE. Univ. of Alberta. *Science Progress* **23**, 75-105(1928).—Ultrasonic waves are of the same type as sound waves, but their pitch is too high for audibility. Their chem. and biological effects are noted, and a bibliography is given. **JOSEPH S. HEPBURN**

The discontinuity of matter. JEAN PERRIN. *Rev. sci.* 66, 97-104, 129-36(1928).—An address on the at. theory. JOSEPH S. HEPBURN
A. PAPINEAU-COUTURE

Evidence for the continuous creation of the common elements out of positive and negative electrons. R. A. MILLIKAN AND G. HARVEY CAMERON. *Proc. Nat. Acad. Sci.* 14, 445-50(1928); cf. *C. A.* 22, 1900. J. E. S.

Theory of Hartree's atomic fields. J. A. GAUNT. *Proc. Cambridge Phil. Soc.* 24, 328-42(1928).—A mathematical paper. The conclusion is reached that of all methods of approximating to the wave-function and energy of a complicated atom by solving equations for the individual orbits, Hartree's method (*C. A.* 22, 1269) is the most generally effective in reducing the first-order error in the wave-function and the second-order error in the energy. The expressions for the total energy of the atom are theoretically more sound than those for the sep. x-ray terms, though of less practical value. J. M. B.

Temperature radiation. W. E. FORSYTHE. *J. Optical Soc. Am.* 16, 307-28 (1928).—A general review of the development of our ideas of temp. radiation during the past 50 years is given, with special emphasis on the investigations made since 1900.

W. W. STIFLER

The contours of stellar absorption lines, and the composition of stellar atmospheres. CECILIA H. PAYNE. *Proc. Nat. Acad. Sci.* 14, 399-406(1928).—Unsold's (*C. A.* 22, 539) formula is applied to spectral data of some stars. The theory gives excellent comparative data about the atms. of stars. ARTHUR FLEISCHER

Width of the lines of the Balmer series. (MLLE.) M. HANOT. *Ann. phys.* [10], 8, 555-625(1927); cf. *C. A.* 21, 1226.—The width of a line is defined as the wave-length interval over which the av. intensity of illumination is equal to one-half of the intensity max., although this does not necessarily completely characterize the distribution of energy over the line as supposed by some. The width of the primary lines in the Balmer series has been studied for a spark spectrum in H, the conditions being closely defined by measurements of capacity, potential and frequency of the circuit. The width of the lines was measured by a photomicrometric method, a Rowland grating being used. For a given initial temp. and pressure, the width l of the lines is detd. by the intensity of the current traversing the spark, according to the law $l = f(I_0)$, where I_0 is given by $I_0 = V\sqrt{C}/L$ and so represents the max. intensity of current in an undamped circuit. The width increases very rapidly with rising I_0 for small intensities and then tends to a max.; its variation with pressure p is given approx. by $l = l_1 \times p^m$, where l_1 is a const. and m is very close to unity for small intensities but decreases with increasing I_0 down to $2/3$. The chief causes of the enlargement of lines are (a) the absorption by the source of some of its own radiation and (b) the intermol. field due to ions and quadruplets. The magnitude of the former was studied experimentally by passing radiation from one spark through a second; for $I = 300$ amp. the width of the lines due to a very small region of the source is thus found to be 85-90% of the total width. The main cause of enlargement, however, is the intermol. field due to the ions, which has a mean value of 10^6 v./cm., and is proportional to the $2/3$ power of the ionic d. The effect of the quadruplets is secondary, being greater for large currents than for small, while the absorption effect is greater in the small-current region, as expected by theory. The sum of these 2 effects is approx. const. at 10-15% of the width of the line. Like l , the c. d. in the spark follows a law of the form $i = \phi(I_0)$, so that the theory explains the independence of the width of the lines and the damping of the circuit. B. C. A.

Simple derivation of the hydrogen energy levels in wave mechanics. A. E. RUARK. *J. Optical Soc. Am.* 16, 40-3(1928).—Math. The values of the energy levels corresponding with the circular orbits in Bohr's theory of the H atom have been derived by wave mechanics. B. C. A.

Experiments on transmutation. JOHN A. N. FRIEND. *J. Chem. Soc.* 1928, 1321-4.—Au exposed to Rn gave spectroscopic evidence of the appearance of Ca. Careful examn., however, indicated this was due to traces of Ca in the original specimens. D. G.

A projection electroscop for standardizing radium preparations. L. F. CURTISS. *J. Optical Soc. Am.* 16, 363-6(1928).—By projecting on a glass scale the image of a fiber attached to the Au leaf of an electroscop, the eye-strain due to the use of a microscop and the danger to the observer from proximity to γ -radiation are eliminated. D. G.

Extraction of radium and mesothorium from radioactive chlorides in the cold. I. BASHILOV. *Z. angew. Chem.* 41, 57-9(1928).—A description of a tech. method al-

ready patented, for the sepn. of Ra or mesothorium chloride from BaCl₂ without evapn. The mixed chlorides are dissolved in water, and a quantity of strong CaCl₂ soln. is added sufficient to ppt. at most $\frac{1}{2}$ of the BaCl₂ present, which then contains about twice as much active chloride as the original mixt. By repeated fractional pptn. a product rich in Ra or MsTh is obtained, together with a soln. of Ba and Ca chlorides, which are recovered by evapn. and crystn. The process is suitable for working up chloride mixts. contg. as little as 0.1 part per million of radioactive chloride. Al and ferric chlorides may also be used as pptg. agents, but as they are susceptible to hydrolysis CaCl₂ is preferred.

B. C. A.

Free electrons, atoms and light. SUZANNE VEIL. *Rev. sci.* 66, 9-13(1928).—A discussion showing the value of the quantum theory as a working tool, but also showing that it cannot explain certain phenomena (such as interference, polarization, etc.), which can readily be explained by the undulatory theory, and that as yet there are hardly any exptl. facts which can be explained by both theories.

A. PAPINEAU-COUTURE

Sommerfeld's electron-theory of metals. EDWIN H. HALL. *Proc. Nat. Acad. Sci.* 14, 370-7(1928).—H. criticizes adversely the Sommerfeld theory (*C. A.* 22, 1538). According to S.'s theory, calcn. shows that the kinetic energy of an electron in a metal at 0° abs. is 80 times the kinetic energy of a gas mol. at 300° abs. and 22 times the kinetic energy at 1100° abs. (extensive thermionic emission from metals at this temp.) The theory does not give an adequate conception of mean free path of electrons in the equation for elec. cond., and gives no explanation for supra-cond. New data on the Wiedemann-Franz law support Drude's equation and not the equation derived by S. S.'s theory gives inadequate explanation and questionable equations on thermionic emission, electron emission from cold metals, the Volta effect, and the Thomson and Peltier effects.

ARTHUR FLEISCHER

The Fermi statistical postulate: examination of the evidence in its favor. EDWIN H. HALL. *Proc. Nat. Acad. Sci.* 14, 366-70(1928).—The basis of the Fermi statistical mechanics is the extension of Pauli's principle to a large no. of mols. This is a doubtful step when applied even to a mol. of gas. The Fermi postulate is directly opposed to the Bose-Einstein statistics regarding the direction of deviation of ideal gases from the classical laws at low temp. The Fermi hypothesis is on trial and depends on the success of Sommerfeld's electron-theory of metals.

A. F.

Electron "free-path" and supra-conductivity in metals. EDWIN H. HALL. *Proc. Nat. Acad. Sci.* 14, 377-80(1928).—The mean free-path is defined as the distance during which the electron is subjected to the accelerating force of the potential gradient which maintains the current. The free path terminates when the electron is captured by a positive ion. From these definitions it is shown that the elec. cond. of a metal is independent of the no. of free electrons. This disposes of the difficulty in the classical theory of the thermal agitation of the free electrons increasing the sp. heat, since few free electrons may be assumed to be present. The change of cond. with temp. is explained on the basis of a quicker capture of the electrons by the positive ions. With supra-cond. the no. of electrons which may go over to ions is exceedingly small. These ions continue under an initial potential at the low temp.

ARTHUR FLEISCHER

Ions and electrons in the vacuum lamp. P. SELÉNYI. *Physik. Z.* 29, 311 8 (1928).—The electron and ion phenomena which take place in a vacuum lamp or which can be produced by it are described systematically. The behavior of the lamp or that of the ions and electrons towards electrostatic, magnetic and electromagnetic influences are discussed. It has been shown that the vacuum lamp can function as detector, rectifier, voltmeter, magnetron, photocell and vacuum meter. Some investigations carried out with vacuum lamps are mentioned (detection of Th in the burning filaments, detection of O formed in the electrolysis of glass). Some methods of the detn. of vacuum in the ready-made lamps are discussed briefly.

M. R. FENSKÉ

Angular distribution of slow electrons on passing through metal films. E. RUPP. *Ann. Physik* 85, 981-1012(1928).—Films of Al, Pb, Ni, Cu, Ag, Au, Cr, Sn and Zn were formed by condensing the metallic vapor on polished rock-salt plates in a high vacuum. The films were from 2 to 8×10^{-8} cm. thick. Electrons, with velocities corresponding to 180 to 320 v., after passing through these films were recorded photographically. A no. of these photographs are reproduced. In addn. to the spot corresponding to the direct beam, there are distinct evidences of electrons scattered in coherent rings about the central spot. These "electron diffraction rings" are similar in appearance to the patterns formed in the Debye-Scherrer method of x-ray spectroscopy. R. shows that these can be coordinated with the known lattice planes of the metals forming the films by the expanded de Broglie-Schrödinger relation, $\lambda = h/\sqrt{2em} \times 1/\sqrt{V + E}$, where λ is the "wave-length" according to the de Broglie-Schrödinger theory, V is the measure of

the velocity and E is a const., the "inner lattice potential," which is characteristic of the given metal and independent of the velocity of the electrons. For the metals investigated, E lies between 10 and 20 v. The results are coordinated with those of Davisson and Germer (*C. A.* 22, 350). The original paper should be consulted for the tabulated numerical results as well as for the excellent reproductions of the "diffraction patterns" and the detailed theoretical discussion.

W. W. STIFLER

Further experiments on the passage of electrons through slits. R. WHIDDINGTON, Univ. of Leeds. *Proc. Leeds Phil. Lit. Soc.* 1, 242-5(1928); cf. *C. A.* 21, 2221; 22, 2877.—Averages are given from several hundred photographs. The accuracy is about 0.2 v. The slit was 0.1 mm. wide in Cu foil. The oxide-coated filament was placed less than 10 mm. from the slit *in vacuo*. The impacting voltage was about 100 v. and the thermionic current was a few milliamperes. The electrons passing through the slit were deflected by a magnetic field. Beside the full velocity line, there were lines 3.9, 9.6, 11.4, 19.8, 22.6, 26.4, 32.3, 38.7, 45.0 and other variable lines up to 60 v. below the full potential line. When a pure Pt emitter was used lines 4.0 and 7.5 v. below the full potential line were found. The strongest line below the full potential line with the coated emitter is the one 11.4 v. below, and 22.6, 32.3 and 45.0 might be 2, 3 and 4 times this line. H in contact with Cu has a radiation line at 11.2 v. Multiple collisions would account for this series of lines. The lines at 9.6 and 19.8 might be a pair of such lines due to collision with O_2 from the coated filament. The lines from the uncoated filament could be due to Cu. With a W-emitter and high voltages, lines above the full velocity appeared. This is probably due to the fact that the elec. field penetrates through the slit.

F. E. BROWN

Some experiments on Geiger ion counters. RALPH D. BENNETT. *J. Optical Soc. Am.* 16, 339-54(1928).—The Geiger ion counter consists of a gas-filled chamber into which an insulated electrode, terminating in a more or less sharp point, is inserted. The point is usually kept neg. with respect to the chamber. The method of constructing satisfactory points from fine Pt wire is outlined. B. gives the results of expts. on the reliability and usefulness of the counter as influenced by varying the size of point and chamber, and the position of point in chamber. He also investigated the effect of voltage on sensitivity, effect of nature and pressure of gas used, sensitivity to ultra-violet light and to ions of small energy, effect of various properties of the elec. circuits used for amplification or detection, and the time lag of the action of the counter. Conclusion: While the counter can be made very sensitive for the detection of single ions, it is only a moderately sensitive detector of ultra-violet light. The conditions under which it can be used quantitatively as well as qualitatively are indicated and some theoretical suggestions are made as to the exact mechanism of its action. The original paper should be consulted by anyone working with an ion counter. A bibliography is included.

W. W. STIFLER

Photoelectric and thermionic properties of iron. ALVIN B. CARDWELL. *Proc. Nat. Acad. Sci.* 14, 430-45(1928).—A narrow strip of electrolytic Fe was suspended inside a Ni receiving cylinder and the whole was enclosed in a Pyrex tube which was connected through a liquid-air trap and Hg cut-off to the pumps. A quartz window, sealed directly to the Pyrex tube, admitted radiation from a quartz Hg lamp. The significance of the results lies in the great care taken *completely to outgas* the Fe. This preliminary rept. includes the following results: (1) As the Fe undergoes a process of outgassing extending over more than 200 hrs., the photoelec. current at first increases enormously and then decreases as greatly during the first 10 hrs. of heating at 300°. Later heating up to 875° produces a rather irregular increase in photoelec. current, but eventually after about 120 hrs. a steady value is reached which shows no fatigue over a period of several hrs. (2) Even after thorough outgassing (pressure 10^{-8} mm. of Hg) the variation of photoelec. current with temp. is quite complex. The decrease in photosensitivity between 475° and 768° is interpreted as a pure temp. effect. From 768° to 910° the sensitivity remains const. or increases slightly. This is probably due to the transition from α to β Fe, which involves a slight increase of the edge of the unit cube without change in cryst. form. The transition at 910° from β to γ Fe (involving a change from body-centered to face-centered cubic lattice), is marked by a sudden decrease in sensitivity, followed by an increase. (3) The thermionic current curve shows a sudden break at 910°. (4) The long wave-length limit lies between 2580 Å. U. and 2652 Å. U.

W. W. STIFLER

Mobilities of gaseous ions in sulfur dioxide and in sulfur dioxide-hydrogen mixtures. L. DUSAULT AND LEONARD B. LOEB. *Proc. Nat. Acad. Sci.* 14, 384-93(1928); cf. *C. A.* 22, 1903.—The previously described app. was used. It was shown that fine gauzes give variable results. SO_2 was very difficult to purify. Four av. results

gave mobilities of 0.336 cm./sec. (on the new scale) for pos. ions and 0.316 for neg. One sample of SO_2 , probably very pure, gave values of 0.484 and 0.443 for pos. and neg. ions, resp. There is an increase in the mobilities for both ions with decrease in pressure, agreeing with the theory of Alexeievsky, but deviating from the inverse-pressure law. Electrons attach to SO_2 to form neg. ions nearly as readily as they do to Cl_2 . Small quantities of SO_2 in H_2 increased the mobilities of the pos. ions to very high values, up to 22 cm./sec. This is higher than any neg. mobility found in H_2 . A. F.

Focusing electrons reflected or emitted at equal angles from a plane surface. D. A. WELLS. *J. Optical Soc. Am.* 16, 355-6(1928).—A method is outlined for using a transverse magnetic field to bring to a line focus electrons reflected or emitted with the same energy and at any given angle from a plane surface. The theory is given briefly by means of 2 diagrams and it is shown that when the breadth of the reflecting surface is small in comparison to the radius of the path of the electrons, this straight line focus lies on the surface of a cylinder having the same radius as the path of the electrons. No exptl. details or data are given. W. W. STIFLER

The dielectric constant of a mixture of benzene and toluene under the action of short electric waves. R. D. SHULYAS-SOROKINA. *Z. Physik* 48, 426-36(1928).—By the examn. of the refractive index of a benzene-toluene mixt. with damped elec. waves, A. R. COLLEY (*C. A.* 4, 15) found an effect comparable to the photoeffect. S. investigates the dielec. const. of the same mixt. with undamped waves, and finds nothing comparable to the photoeffect. One half of the paper is devoted to the description of the technical details. A. L. HENNE

The spectral system of Röntgen rays and atomic structure. A. DAUVILLIER. *Rev. Sci.* 65, 705-16(1927).—An address reviewing the work done during the last 20 yrs. A. PAPINEAU-COUTURE

Experimental study of the absorption formula of the x-rays. I. M. ISHINO AND S. KAWATA. *Mem. Coll. Sci. Kyoto Imp. Univ.* 10, 311-6(1927).—The variation of the absorption coeff. of x-rays with the at. no. of the absorbers has been studied for the absorption of the $K\alpha$ line of Mo. The absorbers were chiefly used in the form of salts dissolved in water. The results are in substantial agreement with those of Wingårdh (*C. A.* 16, 2072). B. C. A.

Dispersion of long-wave-length x-rays in platinum and calcite. ELMER DERSHEM. *Proc. Nat. Acad. Sci.* 14, 380-4(1928).—Anomalous dispersion of the type predicted by theories of Kronig and of Mark and Kallman was found for Pt and calcite, although quant. agreement is doubtful. ARTHUR FLIJSCHER

The absorption of ultra-violet light by carbohydrates. L. KWIECINSKI, J. MEYER AND L. MARCHLOWSKI. *Z. physiol. Chem.* 176, 292-3(1928).—The selective absorption reported by Niederhoff for certain sugars is believed to be due to impurities the complete removal of which is extremely difficult. A. W. DOX

Spectroscopic analysis of light obtained by molecular diffusion of monochromatic radiation within a fluid. J. CABANNES AND P. DAWÉ. *Compt. rend.* 186, 1533-4(1928).—C. and D. analyzed the diffused light obtained in the Raman effect (*C. A.* 22, 1079), using an interferometer and spectrograph. The diffusion spectra for lines Hg 4358 and 4046 show in each case at least 4 secondary λ 's of lower frequency than exciting λ . The differences between the exciting frequency and the secondary frequencies are the same in both cases. The expected symmetrical higher frequencies have not been observed. A. P. S.

Sensitiveness of the spectral lines. TR. NEGRESKO. *J. chim. phys.* 25, 363-403(1928); cf. *C. A.* 21, 3553.—N. studies the influence of decreasing the percent of an element in an alloy on its spectrum. The range of his study is from 2000 to 6500 Å. U Bi, Si, Cd, Co, Zn, Mg, Hg, Al, Ag, Cu, Sb and C have been examd. in numerous alloys. The results are tabulated, with special reference to the concn. limit at which a definite line disappears. When the percent of an element decreases, all its lines fade progressively. The lines which remain longer visible are also the stronger ones. At each moment the line's intensity is proportional to the concn. of the element in the volatilized material, no matter what the state of excitation of the atom is. In flames or metallic vapors bombarded by electrons the more sensitive lines are emitted by the neutral atom; in spark, they are emitted by the ionized atom. A. L. HENNE

An ultra-violet light filter. FELIX SAUNDERS. *J. Optical Soc. Am.* 16, 382(1928).—A 0.2 M aq. soln. of *K H phthalate* is completely opaque to ultra-violet light at and beyond 3000 Å. U. wave length. D. G.

Optical properties of selenium in the conducting form. (Miss) P. M. NICOL. *J. Proc. Roy. Soc. New South Wales* 60, 60-72(1928).—The extinction coeff. x and n of Se for wave lengths of 4400-7100 Å. U. detd. from measurements with Se mirrors, are

independent of the temp. at which the Se was transformed into the conducting variety, and alter little, if at all, with exposure to light and with increasing age. With increasing wave length, α decreases and n increases. B. C. A.

Contributions to the knowledge of the sulfide phosphors. ILSEMARIE SCHAPER. Univ. Heidelberg. *Ann. Physik* 85, 913-52(1928).—Exhaustive details are given of the prepn. and properties of CaSSb , SrSSb , CaOSb , SrOSb , MgS phosphors with respect to regions of excitation and emission, effect of temp., behavior towards infra-red radiation and excitation by flames. The general behavior of the new phosphors is in accord with that previously reported by Lenard and his co-workers. The dielec. consts. of the new phosphors are surprisingly low, varying between 3.94 and 7.57 for CaSSb according to conditions of prepn.; phosphors prepd. without addn. of alk. phosphates, etc., have specially low dielec. consts. W. WEST

Fluorescence of electrically excited mercury vapor. S. PIENKOWSKI. *Compt. rend.* 186, 1530-2(1928); cf. *C. A.* 21, 3561.—An annular transparent silica tube with plane parallel windows, liquid Hg electrodes and Hg vapor in motion was used. The density of Hg vapor varied by changing the heating current. This Hg vapor was illuminated by a flat luminous beam from a Hg-vapor lamp. Decreasing vapor density renders well-known green fluorescence feebler and the path of the exciting beam becomes finally invisible. Colored filters show fluorescence to be due to a blue-violet region of the spectrum, chiefly line 4358. A preliminary spectrum analysis of the fluorescence shows the lines $2^3\text{S} - 2^1\text{P}_2$ and $2^3\text{S} - 2^3\text{P}_1$ to have the greatest intensities. The emission of fluorescence is bound up with the return of the latter atoms to their original state. A. P. S.

Active nitrogen. BERNARD LEWIS. Univ. of Minn. *Nature* 121, 938-9(1928).— O_2 , whose presence has been thought to be necessary in the production of glowing active N_2 , was introduced into a vessel contg. pure "glowless" N_2 immediately after discontinuing the discharge. No glow was induced by this procedure. Furthermore little or no glow was produced when the mixt. (1% O_2 at 0.1 mm. total pressure) was subjected to the discharge. Absolutely glowless N_2 could only be obtained by baking out the discharge vessel thoroughly. The results are substantiated by similar results of Herzberg (cf. *C. A.* 22, 1911). L. was able to obtain N_2 after-glows in mixts. contg. up to about 57% O_2 at low pressures (about 0.2 mm.). At higher pressures the type of after-glow changes to one possessing a continuous spectrum, which is attributed to O_2 .

BERNARD LEWIS

Active nitrogen. BERNARD LEWIS. *Nature* 121, 864-5(1928).—Polentical against Willey, *C. A.* 22, 1830. In active N there must exist mols. of energy content greater than 2 v. (as W. assumes), since it is well known that active N can produce many metallic spectra and other actions in which the needed excitation reaches as much as 10 v. W. held that the fact that NH_3 extinguishes the active N after-glow raises a serious objection to L.'s theory of NH_3 formation from active N and H. L. replies that he did get NH_3 , though some of it undoubtedly was decompd. by active N after having been formed but that this is no criterion for or against the theory of NH_3 formation G. G.

The after-glow of nitrogen and oxygen in air. KARL STÖCK. *Z. Physik* 48, 358-9(1928).—A supplement to the work of Herzberg (cf. *C. A.* 22, 1911). Similar observations were made with a spark discharge. A. L. HENNE

Apparatus for observing fluorescence by ultra-violet illumination. G. KÖGEL. *Chem. Fabr.* 1928, 55-6.—The light from a "spot-light" W arc lamp is filtered through a water-cooled quartz filter silvered on the outside to remove visible rays, and the remaining ultra-violet rays are reflected on to the illuminating mirror of a microscope if transparent objects are to be examd., or on to the surface of opaque objects by means of a spherical dark-field illuminator. In order to photograph the fluorescence the ultra-violet rays must be absorbed by passing the emergent light from the eye-piece of the microscope through a 5-mm. layer of a soln. contg. 0.5 g. of triphenylmethane in 70 cc. of alc. The luminescence rays pass unabsorbed through this soln. and are photographed on panchromatic ultra-rapid plates. B. C. A.

The nature of the photoluminescence of uranyl salts. S. T. VAVILOV AND V. L. LEVSHIN. *Z. Physik* 48, 397-425(1928).—The fading of the glow of uranyl salt crystals, U glasses and liquid solns. obeys generally the law $I = I_0 e^{-t/\tau}$. Only when the exciting light is short-wave ultra-violet, a second fading process can be detected in a few substances. In every case investigated, only phosphorescence was present; fluorescence was totally absent. With soln., the temp. and the concn. are the more important factors of the fading duration. The exponential law is always obeyed, and the initial intensity j_0 remains const. In general the fading and the extinction depend on the viscosity of the soln. The light is always unpolarized. It is assumed that the photo-

luminescence of the uranyl salts represents the radiating transition of the metastable state of the excited mol. Several phenomena connected with the disappearance of the luminescence are quantitatively accounted for by means of this assumption.

A. L. HENNE
Radiation hypothesis of chemical reaction. FARRINGTON DANIELS. Univ. of Wisconsin. *Chem. Reviews* 5, 39-86(1928).—The existence of unimolecular reactions has been fully established, but there is no completely satisfactory explanation for their mechanism. The hypothesis that radiation is the important factor underlying chem. reaction was originally based on the existence of unimolecular reactions and the difficulty in explaining them on the basis of collision. This argument is no more valid, since several possible hypotheses based on collisions have been brought out. At present, the most promising explanation lies in the collision hypothesis and the utilization of the internal energy of the mol. and many degrees of freedom. The argument for the radiation hypothesis which was based on the large temp. coeff. of chem. reactions is not valid. The calcn. of the crit. increment and the conception of activated mols. seems satisfactory; neither has been disproved, but the exptl. evidence in favor of them is meager. The simple radiation hypothesis involving the quantum theory has been disproved by a no. of expts. Objections to this hypothesis may be met in several ways, but there is no exptl. backing for them. The reversibility of the relation between chem. reaction and radiation has not been explored very far. Here again the majority of the evidence does not support the radiation hypothesis, but it cannot be said that this postulate of the radiation hypothesis has been disproved. This postulate explains very easily the phenomena of chemiluminescence and fluorescence. Photochem. reactions and chemiluminescence reactions do exist, and radiation must be a factor. Radiation is not important in ordinary thermal reactions.

A. L. HENNE
The mechanism of some chemical photoreactions. II. V. KONDRAT'EV. *Z. Physik* 48, 310-22(1928); cf. *C. A.* 22, 28.—The reaction between alkali metals and CuCl_2 or CuBr_2 vapors at a relatively low temp. occurs on the solid surface as with HgCl_2 and Na. The spectra emitted by these reactions seems to be identical with the CuCl or CuBr spectra. The calcn. of the energy balance shows that the production of these spectra is accounted for by the mechanism proposed for "surface reactions" in the first paper. The "volume reaction" between Na and HgCl_2 is investigated and its mechanism is discussed. A crit. examn. is made to ascertain the conditions required for the transition from "surface" to "space" reaction.

4—ELECTROCHEMISTRY

COLIN G. FINK

Electric furnace for fusing caustic soda. J. S. KEENAN. *Elec.-News* (Toronto) 36, 48-9(1927); *Science Abstracts* 31B, 129.—A description of two 500-kw. elec.-heated furnaces used for fusing caustic soda, in this case a by-product of pulp-bleaching. The

Ni-Cr resistors are hung from fire-brick walls and heat the cast-iron pot by radiation. The temp. of the pot is automatically regulated within \pm or -5° F. by thermocouple control. The pot, which holds 2600 gallons, is supplied with and evaporates 75,000 lbs. of 40% caustic soda soln. in a run of 50 hrs., finally fusing 30,000 lbs. of caustic soda at 800° F. (427° C.). The output of the two furnaces is 60 tons per week, and a saving of \$10,000 per annum over coal firing is estimated.

Electric annealing and normalizing at Timkin plant. M. T. LOTHROP. *Elec. World* 92, 201(1928).—Details of a 1850-kw. furnace installation are described.

C. G. F.

The electrochemistry of alloys (tin-lead). FRIEDERICH VOGEL. *Metallbörse* 18, 145-6(1928).—In preliminary expts., electrolytic Cu (yield 63%) is obtained from a Cu, Sb, Sn, Pb cathode, using as an electrolyte aq. HNO_3 -Cu(NO_3)₂ and CuSO_4 (in sufficient quantity to ppt. any Pb dissolving), over 86.4% of the original metal going into the anode mud. Using dil. aq. HNO_3 -Cu(NO_3)₂, CuSO_4 , and sufficient NaCl to form Na_2SnCl_6 , the yield of Cu increases to 80% (a yield of over 95% by redissolving the anode sludge and electrolyzing), the Sn, Sb and Pb passing quantitatively into the mud. Such electrolytes as those contg. the Cu salts of H_2SO_4 and phenolsulfonic acid were found to be impracticable. *Ibid* 202-3.—Using anodes of alloys contg. 50% Sn, and electrolytes of weak HCl -SnCl₂ with NaCl as the conducting salt, a material contg. 97.5-98.5% Sn deposits on the cathode. All the Pb and Sb go into the anode mud, none going into soln. From a table of potentials it is apparent that under the proper conditions Pb-Sn and Cu-Sb alloys can be formed. In discussing the roles played by the Pb and Sn ions, it is considered that they combine to form a single cation. *Ibid* 371-2.—In the expts. made, a pure Pb electrolyte is used together with an anode of a normal white-metal alloy contg. Sn, Sb, Pb and Cu. The diagrams show that there is a rapid decrease of the Pb ion concn., in the electrolyte, while that of the Sn ion shows an equiv. increase, provided that the voltage necessary for the deposition of Sb or Cu is not reached. Pb deposits until the point of intersection of the two curves, when Sn begins to deposit also. If a Sn electrolyte is used instead of the Pb, analogous curves are obtained; this time the Sn curves decrease while the Pb increase. By varying the proportion of Pb to Sn in the electrolyte, all possible alloys of the two metals may be obtained. A disadvantage of the method is that the exact nature of the alloy cannot be predicted. At these small potentials the amt. of Sb and Cu is so small that their effect is negligible. By remelting and electrolyzing the anodic residue, all of the Pb and 90% of the Sn may be utilized. The regeneration of the electrolytes obtained during the processes is discussed.

J. BALOZIAN

Contact electromotive force. The supposed incompatibility of the law of thermodynamics and the Vasesco Karpen piles. I. Discussion of the calculation of the electromotive forces and of the kinetic theory of diffusion. E. DENINA. *Gazz. chim. ital.* 58, 160-77(1928).—Mathematical, involving a crit. examn. of the exptl. and theoretical work of Vasesco Karpen (cf. *C. A.* 17, 670; 18, 193, 2638, 3135; 22, 545). In conjunction with a theory already developed by D. (cf. *Elettrocista* 35, No. 18(1926)) the present paper shows the generality of the calcn. of contact e. m. fs., based on the concept of mol. forces acting on the various constituent monads and causing the latter to distribute themselves between the 3 phases of contact. The calcons. can be based on the use of distribution coeffs., on an explicit expression of the mol. forces (as was done by K. under the designation "La Place forces"), on thermodynamic potentials, on expansibility tensions, etc. The electrolytic potential calcd. by means of the soln. tensions of Nernst is a special case. The contact e. m. f. between 2 metals can be calcd. by applying the general expressions derived, which are practically equiv. to those obtained from the electronic theory of Lorentz. Certain criticisms of K. of the Nernst theory are discussed and rectified. The phenomena of diffusion are then examd. from the statistical point of view, the equivalence of the formulas of Einstein and of K. being shown, and a general proof is given, the object of which is to define precisely certain indefinite features in the formulas. The relations between the calcd. coeff. of diffusion and the nature of the soln. are discussed. The relations among the distribution equil., the e. m. f. of contact between the 2 solns. and the 2nd law of thermodynamics are analyzed from the theoretical point of view, and a reason is found for the contradictions found by K. in an arbitrary hypothesis introduced *a priori* in the calcons. and incompatible with the 2nd law of thermodynamics. The latter, correctly applied, leads, instead, to sound relations which are more reasonable than those of K. Finally, it is shown why the circulation suggestion by K. for isothermal contacts is improbable in this case, but is necessary for a rise of temp., and furnishes a plausible explanation of the anomalies encountered in the study of these phenomena by Sorét.

C. C. DAVIS

The new dry rectifiers (copper-cuprous oxide). O. IRION. *Siemens Z.* **8**, 293-7 (1928).—I. reviews the work of Wiedemann and of Pawlowski on the copper sulfide rectifying films and mentions other combinations that have been tried such as those of Pb, Fe, brass, Ag bronze, etc., with their oxides or sulfides. The first dry combination that showed promise of good current-passing ability, reasonable life and small loss was the Cu-Cu₂O element of Grondahl (*C. A.* **21**, 14). The "Protos" rectifier based on Grondahl's idea is described in detail. The efficiency (50%) is claimed to be better than that of most rectifiers on the market today. **ARTHUR H. KOPP**

High-voltage mercury-arc rectifiers. L. SMEDE. *Elec. J.* **25**, 403 (1928).—The new large-output glass rectifiers are described. Two 3-phase rectifiers connected in series give 30 amp. at 10,000 to 15,000 v. **C. G. F.**

Radiation measurements on tungsten lamps. H. C. v. ALPHEN. *Ann. Physik* **85**, 1058-88 (1928).—The energy distribution of radiation from an incandescent W lamp filament in the visible spectrum was investigated by two essentially independent methods. In the photographic method (due to Ornstein), a series of real images was formed by practically monochromatic light isolated by a suitable optical system from different regions of the continuous spectrum. These images were photographed and, simultaneously, energy measurements were made on them with a thermopile. The arrangement was calibrated by substituting for the image the filament of a lamp of known distribution. The pyrometric method is based on the exptl. fact that to any given temp., T , of the W filament there corresponds a temp., T_e , for a black body such that the visible part of the spectrum of the black body at T_e has practically the same relative energy distribution as the W filament at T . Full details of exptl. arrangements for both methods are given, and the various corrections to be applied are discussed. Results for a 6 v. N-filled W lamp by the two methods are concordant. The emission from W in the ultra-violet was detd. photographically as a function of the wave length by comparison with a C-filament lamp of known energy emission. Results are compared with those of Hulbert (*Astrophys. J.* **45**, 149 (1917) and *C. A.* **10**, 1300). **W. W. S.**

Effects of corona in various gases on insulation and losses. C. F. HILL. Westinghouse Lab. *Elec. J.* **25**, 402 (1928).—With the possibility of using various gases and mixts. of gases, other than air, for cooling elec. machines, the question of the life of insulation as affected by corona in the various gases becomes of interest. The exptl. setup consisted of a conducting layer placed inside of a glass tube about 1 in. in diam. and 3 ft. long. Insulation is wound around the outside of the tube and a wire helix around this with a pitch of about one inch. The whole is placed inside a larger glass tube which is arranged so that a gas can be circulated through the system as desired. In the presence of air and the conducting layer and the outer wire helix connected to opposite poles an intense corona takes place around the helical wire and O₂ is formed. This O₂ rapidly attacks all organic insulation materials. They usually become hard and brittle. In pure hydrogen and N this org. insulation retains its good qualities. **C. G. F.**

Pressure electrolysis of water eliminates need for compressors. J. E. NOEGGERATH. *Chem. Met. Eng.* **35**, 421-4 (1928).—See *C. A.* **22**, 2114. **E. H.**

The electrolytic preparation of the borides of calcium, strontium and barium. L. ANDRIEUX. *Compt. rend* **186**, 1537-9 (1928).—A description of A.'s method of obtaining CaB₂, SrB₂ and BaB₂ by electrolyzing a melt of the borate and fluoride of the resp. metals. The electrolysis is carried out at 1000° with a voltage of from 5 to 7 and an amperage of 20. **WILLIAM F. EHRET**

Pfannhauser, W.: Die elektrolytischen Metallniederschläge. Lehrbuch der Galvanotechnik mit Berücksichtigung der Behandlung der Metalle vor und nach dem Elektroplattieren. 7th ed., revised and enlarged. Berlin: J. Springer. 912 pp. R. M. 40. Reviewed in *Chemistry and Industry* **47**, 728 (1928).

Electric battery. HENRY CSANYI (to Dry Storage Battery Corp.). U. S. 1,675,973, July 3. The negative electrode is formed of metal such as Zn, the positive electrode of C, the electrolyte of NH₄Cl and the depolarizer of C, Mn hydroxide, MnO₂, NH₄Cl and AlCl₃.

Dry-cell electric battery. HENRY CSANYI. U. S. 1,676,007, July 3. A depolarizing mixt. is formed of Mn hydroxide, C, MnO₂ and NH₄Cl.

Dry-cell electric battery. LAURENCE V. ELLIS. U. S. 1,676,945, July 10. Structural features.

Photoelectric cell. VLADIMIR K. ZWORYKIN (to Westinghouse Elec. & Mfg. Co.). U. S. 1,677,316, July 17.

Storage battery. CORNELIUS AMBRUSTER. U. S. 1,675,321, July 3. Structural features.

Storage battery. RAYMOND A. KLOCK and THEODORE B. ENTZ (to Gould Storage Battery Co.). U. S. 1,675,978, July 3. Structural features.

Storage battery grid. REGINALD S. DEAN and WILLIAM E. HUDSON (to Western Electric Co.). U. S. 1,675,643, July 3. Grids are formed of a Pb alloy which may also contain Sb 2.25% and which carries finely divided particles of solute material such as Sb uniformly dispersed throughout the Pb.

Separator for storage batteries. RAYMOND C. BENNER (to Prest-O-Lite Storage Battery Corp.). U. S. 1,677,512, July 17. Separators are formed of fibrous material such as sulfite pulp bonded with rubber or other suitable acid-resisting plastic material and the pores of the separator are initially obstructed by material such as silica gel which is capable of yielding a gelatinous, acid-proof decompn. product or residue permeable by the electrolyte. Cf. C. A. 22, 734.

Hydrometer suitable for use with electric batteries. FRANK E. SODE. U. S. 1,677,801, July 17. Structural features.

Carbon electrodes. IMRE SZARVASY. U. S. 1,675,674, July 3. A gas contg. CH_4 , e. g., natural gas, is dissoed. by heat in such a manner that a mixt. of finely divided C and tar-like products and also solid coherent C are formed; all these materials are mixed together, coked and ground and used with a binder, molded into electrodes and burned.

Electrode holder for electric furnaces. FERDINAND WECKERLE (to Studiengesellschaft für Wirtschaft u. Industrie, G.m.b.H.). U. S. 1,675,742, July 3.

Electrode holder for closed electric furnaces. JACOB DION (to I. G. Farbenind., A.-G.). U. S. 1,677,712, July 17.

Film-forming electrolyte. HUMPHREYS O. SIEGMUND (to Western Electric Co.). U. S. 1,675,828, July 3. An electrolyte suitable for power plant condensers comprises an aq. soln. such as may be formed from NH_4OH and H_3BO_3 or other suitable base and acid in such proportions as to give a specific resistance value of 150–800 ohms per cc. and a p_{H} of 6.8–7.8.

Electrolytic rectifiers. H. G. ANDRE. Brit. 280,751, Jan. 28, 1927. The cathodes are surrounded by colloidal Ag above which is a mass of H_2SO_4 and sand covered with petroleum jelly or similar material. Various other features are described.

Electric resistances. H. ANDRE. Brit. 280,862, Nov. 17, 1926. A resistance material of high negative coeff. is formed by melting Ag with a metalloid such as P. The resistance may have Ag terminals and may be protected by a layer of cast S.

Electric induction furnace. REINHOLD GROSS (To Siemens & Halske, A.-G.). U. S. 1,676,545, July 10.

Rotary-firing electric induction furnace. EDWIN F. NORTHRUP (to The Ajax Metal Co.). U. S. 1,677,528, July 17. A furnace is specified which is adapted for melting metals.

Electric resistance furnace of the shaft type. THADDEUS F. BAILEY. U. S. 1,675,744, July 3. A furnace is described adapted for producing Fe, Si and graphite. The molten charge may be passed downwardly through loose carbonaceous resistor material.

High-frequency electric furnace adapted for treating rare or refractory metals. HARVEY C. RENTSCHLER and JOHN W. MARDEN (to Westinghouse Lamp Co.). U. S. 1,676,926, July 10.

Constant-temperature electrically heated oven. WINFIELD H. STANNARD (to Central Scientific Co.). U. S. 1,676,876, July 10. Structural features.

Rotatable apparatus for electroplating small articles. JOSEPH DE VERRE. U. S. 1,677,817, July 17.

Tungsten. COLIN G. FINK. U. S. 1,675,486, July 3. There is incorporated in a slug of W material a small quantity of an addnl. substance such as Zr 1.4 and Cu 2–3% which has a high affinity for H at elevated temps. and is capable of reacting with intercryst. impurities and the slug is then heated in H to remove the impurities. The product is ductile and relatively soft and non-sagging in filament form.

5—PHOTOGRAPHY

C. E. K. MEES

Bleachout paradoxes. LÜPPO-CRAMER. *Phot. Ind.* 25, 1099-1100(1927).—Un-ripened lantern slide emulsions were thoroughly washed to remove all traces of sol. bromide. When flashed and then bathed in phenosafranine (1:5000 and 1:20,000) the dil. soln. gave the greater bleaching action with white light. Similar results were obtained with pinakryptol green, tetramethylphenosafranine and tetraethylphenosafranine. When tried with ripened plates or faster emulsions the bleach action was proportional to the concn. of the bath. The plates flashed and then bathed in tetramethyl- and tetraethylphenosafranine gave a higher max. density in the re-reversal when bleached with white light than was obtained on the shoulder of the normal negative curve for untreated plates with the same development. This is ascribed to sensitization by desensitizer. Addn. of bromide to the desensitizing bath gave increased bleach and less re-reversal. Bleaching with red light gave less speed but no re-reversal.

C. E. MEULENDYKE

Fastness to washing of dyed silver bromide. LÜPPO-CRAMER. *Phot. Korr.* 63, 193(1927).—Lumière and Seyewetz have concluded that the action of sensitizing dyes on AgBr is fundamentally different from that of desensitizing dyes; a complex that is more stable, as shown by its greater resistance to dissocn. on washing, is formed with the sensitizing dyes. L.-C. cannot agree with this conclusion. In L.-C.'s experience, the degree of stability on washing is a "quite individual property" of the particular dye. Using plates of a pure AgBr emulsion that had been well washed and had received no further addn. of sol. bromide before coating, and sensitizing to yellow by bathing in 0.002% soln. of erythrosin, pinaflavol nitrate, rhodamine B and isoquinoline red, resp., he has observed that after washing for several hrs. the yellow sensitivity is diminished with rhodamine and pinaflavol although actually increased with erythrosin and isoquinoline red.

E. R. BULLOCK

Defects in sulfide-toned images. K. KIESER. *Phot. Ind.* 25, 1257-8(1927).—Bluish spots or flecks may occur on toned prints especially with age. This is caused by insufficient washing in which unremoved ferricyanide reacts with Fe^{+++} impurity in the paper base or wash H_2O to form Prussian blue. Acid bleach baths tend to hold back ferricyanide to a greater degree. The reaction between ferricyanide and Fe^{+++} is inhibited by presence of alkali such as that obtained by a final bathing in a weak soln. of Na_2CO_3 . Careless washing after the bleach bath may be partly compensated by careless washing after the Na_2S redeveloper, caused by the retaining of slight alkyl.

C. E. MEULENDYKE

Sensitometry of reversal emulsions. L. LOBEL AND J. LAFÈVRE. *Bull. soc. franç. phot.* 14, 288-97; *Kinochnik* 9, 503-7(1927).—The reversal process involves 3 essential steps. (1) development; (2) soln. of the Ag; (3) (complete) blackening of the remaining AgBr. The gamma of the positive curve equals the gamma of the negative curve, and the height of the positive curve above the exposure axis depends on the max. black of the emulsion. If the max. black is lowered by a solvent developer, the positive curve is also lowered. A pure white in the subject must be reproduced in the film by a Ag density of zero, and the contrast of the picture must equal the contrast of the subject. It follows that the solarization density must equal the max. black and the negative gamma infinity must equal one, since the solarization density is reached only by developing to gamma infinity. The camera exposure must be sufficient to make the $I. t$ value for a pure white equal the solarization exposure. The sensitivity of a reversal emulsion is detd. by the exposure necessary to reach the solarization value. It can be expressed as the abscissa of the intersection of the straight-line portion of the positive curve with the exposure axis.

C. E. IVES

Denuculation and desensitization. LÜPPO-CRAMER. *Phot. Korr.* 63, 362-3(1927).—L.-C. calls attention to his article (*C. A.* 19, 18), and describes a repetition of those expts. giving, however, the same standard exposure after each kind of treatment. One strip of a plate of each of 5 different brands was bathed in chromic acid mixt. for 3 min., washed for 2 hrs. and dried; another strip was bathed in 0.01% phenosafranine soln. for 2 min., and dried; and a third was treated first with the chromic acid and then with the phenosafranine. These 3, together with an entirely untreated strip, were exposed under a Goldberg wedge, developed and densographed. Six lantern or process plates were then treated similarly, with the exception of being given 10 times the exposure. It is seen that the denucleated (that is, chromic acid treated) plates are appreciably less affected by the desensitization (that is, phenosafranine treatment) than are the origi-

nal plates; and from this L.-C. concludes, as before, that desensitizers attack predominantly the original ripening nuclei. It does not follow, however, that a plate containing originally less nuclei would be more strongly desensitized than a high-speed plate.

E. R. BULLOCK

Constitution of the flavinduline desensitizers. G. KÖGEL. *Phot. Korr.* **63**, 193-5 (1927).—An account is given of K.'s work in 1922 on the prepn. and properties of several derivs. of flavinduline. It is mentioned that nitro groups cause the disappearance of "bleaching-out" but not of the desensitizing property.

C. E. MEULENDYKE

Errors produced in slow development with glycine. A. AND L. LUMIÈRE AND A. SEVEWETZ. *Bull. soc. franç. phot.* **14**, 306-8; *Photographe* **14**, 467-8 (1927).—Almost invisible oxidation scum which forms on the surface of glycine developers has ruined many negatives. As the negative is put into the developer the scum becomes attached to all or part of the surface and prevents development. The defect is worse than that sometimes encountered with pyro. Skimming or filtering the developer is of no help but if the negative is soaked in H_2O previous to development the spotting usually does not occur. It is preferable to use an elon-hydroquinone slow developer which produces negatives equal to those developed in glycine.

C. E. IVES

Coloring photographs (U. S. pat. 1,676,739) **18**.

Photograph for viewing as a positive by reflected light or for use as a negative in printing by transmitted light. SAMUEL B. SHEPPARD (to Eastman Kodak Co.). U. S. 1,676,580, July 10.

Photographic process. EASTMAN A. WEAVER (to Technicolor Motion Picture Corp.). U. S. 1,677,665, July 17. In producing a photographic printing matrix, a film is printed with light distributed to produce a latent image in the film and the contrast gradations of the image are altered by exposing the film with correspondingly distributed light, the altered latent image is then converted into a photographic printing matrix.

Photographic developers. I. G. FARBERIN. A.-G. Brit. 280,525, Nov. 13, 1926. A cyanide such as that of Hg, Co or Cd is added to a photographic developer to desensitize the sensitive Ag halide layer in the first stage of development and permit the completion of development in bright yellow light. $Hg(CN)_2$ 0.03% may be added to a developing soln. contg. metol and hydroquinone. Tendency to fogging is checked by the treatment.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

The complex chloro salts of bismuth. H. REMY AND L. PELLENS. *Chem. Staatsinstitut, Hamburg, Univ. Ber.* **61B**, 862-8 (1928).—This is one of a series of papers (cf. C. A. **15**, 3007; **20**, 25; **21**, 3846) of which the object is to study the mechanism of coordinative combination. Calcn. from the Coulomb law and Goldschmidt's ion radius of the energy of formation for chloroferriate ions shows that the tetrachloroferriate ion is most stable. The agreement between expt. and theory for the chloro complexes of Fe and Bi seems to indicate that from atom or ion radius can be predicted the possibility of existence and the compn. of complex compds. The exptl. work included a study of many known complex Cl derivs. of Bi together with the following new compds.: *methylammonium enneachlorodibismuthate*, $(MeNH_2)_3Bi_2Cl_9$, m. 302°; *methylammonium hendecachlorodibismuthate*, $(MeNH_2)_3Bi_2Cl_{11}$, decomp. slowly above 240°; *methylammonium heptachlorobismuthate*, $(MeNH_2)_3BiCl_7$, softens 210° and then melts with decompn.; *dimethylammonium pentachlorobismuthate*, $(Me_2NH)_2Bi_2Cl_5$, m. 228°; *dimethylammonium heptachlorobismuthate*, $(Me_2NH)_2BiCl_7$, m. 208°; *trimethylammonium enneachlorodibismuthate*, $(Me_3NH)_3Bi_2Cl_9$, softens 260°, m. (not sharply) 284°; *trimethylammonium hexachlorobismuthate*, $(Me_3NH)_3Bi_2Cl_6$, m. (not sharply) 272°; *tetramethylammonium tetradecachlorotribismuthate*, $(Me_4N)_3Bi_3Cl_{14}$, m. 286° (decompn.); *ethylammonium tetrachlorobismuthate*, $EtNH_2BiCl_4$, m. 158°; *ethylammonium pentachlorobismuthate*, $(EtNH_2)_2BiCl_5$, m. 268°; *ethylammonium hexachlorobismuthate*, $(EtNH_2)_2BiCl_6$, m. 239°; *ethylammonium heptachlorobismuthate*, $(EtNH_2)_2BiCl_7$, m. 199°; *propylammonium tetrachlorobismuthate*, $PrNH_2BiCl_4$, m. (not sharply) 157°; *propylammonium pentachlorobismuthate*, $(PrNH_2)_2BiCl_5$, m. 243°; *propylammonium heptachlorobismuthate*, $(PrNH_2)_2BiCl_7$, m. (not sharply) 170°; *butylammonium*

pentachlorobismuthate, $(\text{BuNH}_2)_3\text{BiCl}_2$, m. 225° ; and *butylammonium enneachlorobismuthate*, $(\text{BuNH}_2)_9\text{BiCl}_3$, m. 180° . A. L. HENNE

The metallic cyanates. III. The amines of the simple cyanates with hexamethylenetetramine. R. RIFAN. Univ. of Cluj. *Bull. soc. stiinte Cluj* 4, 28-42 (1928); cf. C. A. 22, 1740.—The diaquoammonohexamethylene tetramino metallic cyanates,

$\left[\text{M}^+ \text{Urt}_p \right] (\text{H}_2\text{O})_2 (\text{CNO})_2$, were prepd. by treating aq. solns. of the metallic salts with solns. of KCNO and then adding a soln. of urotropine (Urt_p). M⁺ corresponds to Co, Ni, Mn, Fe, Cu and Cd. These compds. all hydrolyze in hot H₂O. They are insol. in alc. ether and benzene. They all dissolve in pyridine (Py) to form the corresponding tetrapyrindine complexes. They are all sol. in aq. NH₃ solns, probably forming another sol. ammine. Their color depends upon the nature of the metallic element in the complex.

The Cu complex was changed by boiling in MeOH into the green, stable $\left[\text{Cu} \text{Urt}_p \right] (\text{MeOH})_2 (\text{CNO})_2$. In a similar way $\left[\text{Cu} \text{EtOH} \right] (\text{CNO})_2$ was formed. The formulas given for the

aquoammines are supported by the fact that the diaquoammino Cu salt loses both mols. of H₂O simultaneously when heated to 80° . Attempts to prep. the corresponding complexes of Pb, Ag, Be, Mg, Al and Cr were unsuccessful. Further conclusions: (1) The introduction of a mol. of a base into the simple metallic cyanate makes the mol. more stable and less sol. (2) The replacement of a H₂O mol. in the ammine by an alc. mol. increases the stability of the complex. (3) Urotropine acts as a bivalent base (4) One mol. of EtOH is equiv. to 2 of H₂O in the complexes. IV. Study of chromium. A new reaction and a new gravimetric method for the determination of this element. *Ibid* 57-61.—The hydrolysis of Cr salts by solns. of KCNO is similar to that described for salts of Al (C. A. 22, 1740). The hydroxide produced from hot solns. is granular and is easily filtered and washed. The reaction serves as the basis of an accurate gravimetric detn. of Cr in the presence of Zn and Mn. The directions for the analysis are the same as those given for Al. The ppt. is ignited and weighed as Cr₂O₃. The inaccuracy is about 0.1%. As little as 0.0002 g. of Cr can be detected. H. F. JOHNSTONE

A new class of amines, the selenocynoamines. I. G. SPACU AND R. RIFAN. Univ. of Cluj. *Bull. soc. stiinte Cluj* 4, 3-22 (1928).—The tetraquodihexamethylene tetramine metallic selenocyanates, $\left[\text{M}^+ \text{Urt}_p \right] (\text{H}_2\text{O})_4 (\text{SeCN})_2$, were prepd. by treating solns. of the metallic nitrates with a soln. of urotropine (Urt_p). M⁺ corresponds to Co, Ni, Mn, Fe and Zn. The compds. are sensitive to light and to air, in which they slowly decompose liberating Se. These amines, as well as those subsequently described, are sol. in pyridine but insol. in alc., ether and benzene. They are hydrolyzed by hot H₂O and by acids. Attempts to prep. the pyridine analogs under similar conditions were unsuccessful, probably because of their rapid hydrolysis. The tetrapyrindine metallic selenocyanates, $\left[\text{M}^+ \text{Py}_4 \right] (\text{SeCN})_2$ (Py = pyridine) (where M⁺ = Co, Ni and Cu) were prepd., however, by first adding a soln. of KSeCN in alc. to a similar soln. of the metallic nitrates, filtering off the metathesized KNO₃, and then adding pyridine. The Mn compd. decomposes in air with the sepn. of Se and formation of the diammine. By dissolving the Ni compd. in hot pyridine and cooling the soln. the hexapyridine Ni complex, $[\text{NiPy}_6] (\text{SeCN})_2$, was obtained in the form of violet crystals. It is less stable in air than the tetrammine. The tetrapyrindine Fe salt, $[\text{FePy}_4] (\text{SeCN})_2$, was prepd. by adding KSeCN in alc. to a similar soln. of FeCl₃·6H₂O. The ferric ions were thus reduced to ferrous. On adding pyridine the yellow tetrammine pptd. The dipyrindine Zn salt, $[\text{ZnPy}_2] (\text{SeCN})_2$, was obtained by using smaller proportions of pyridine. By cooling a hot pyridine soln. of this diammine the tetrapyrindine Zn complex was formed. It decomposes in air and in acids with the sepn. of Se. By using small proportions of pyridine the dipyrindine Cd salt was prepd. in the usual way. The tetrapyrindine Cd compd. was also formed from a hot pyridine soln. of the diammine. It is stable in air but hydrolyzes with ease in hot H₂O. The colors of the complex salts depend on the nature of the metallic element in the mol. In general the properties of the amino-selenocyanates resemble those of the corresponding aminothiocyanates. H. F. J.

The specific action of the oxime group on metal salts. I. Reactions of cobalt, nickel and copper salts with aldoximes. WALTER HIEBER AND FRITZ LEUTGART. Univ. of Heidelberg. *Ber.* 60B, 2296-310 (1927).—The general formula of the additive

compds. is $\left[\text{X}_2\text{M} \left(\begin{array}{c} \dots \text{N} : \text{CH} \cdot \text{R}_1 \\ \text{OH} \end{array} \right)_{2 \text{ or } 4} \right]$, in which X is a halogen and M the metal.

The compds. are nonelectrolytes. They are obtained by direct crystn. of the alc. soln. of the components. The following additive compds. have been obtained: CoCl_2 , CoBr_2 , NiCl_2 and NiBr_2 , with 4 mols. of acetaldoxime; CoCl_2 , NiCl_2 , CuCl_2 with 4 mols. of isobutyraldoxime; CoCl_2 , CoBr_2 , NiCl_2 , NiBr_2 with 4 mols. β -benzaldoxime. α -Benzaldoxime is used for this prepn.; it undergoes rearrangement into β -benzaldoxime, whereupon the additive compd. is formed. Cinnamaldoxime gives the following additive compds.: $\text{CoCl}_2 \cdot 4\text{C}_6\text{H}_5\text{CH}(\text{CH}=\text{CH} \cdot \text{NOH})$ and $\text{CuCl}_2 \cdot 2\text{C}_6\text{H}_5\text{CH}(\text{CH}=\text{CH} \cdot \text{NOH})$. By treating Cu acetate with aldoximes, compds. of a salt-like nature are obtained; Co and Ni do not react in this manner. Upon addn. of a trace of the metal chloride to an alk. soln. of the oximes intensive color reactions are produced which depend upon the formation of complex compds. CuCl_2 gives a compd. with α -benzil α -dioxime having the formula: $\text{C}_6\text{H}_5\text{C}(\text{NOH})\text{C}(\text{NOH})\text{C}_6\text{H}_5 \cdot \text{CuCl}_2 + 2\text{H}_2\text{O}$. II. Reactions of ketoximes with metal salts. *Ibid* 2310-7.— CoCl_2 does not react with acetoxime in aq. soln. Suspensions of CoCl_2 in inert solvents (CHCl_3 , Et_2O , $(\text{CH}_2\text{Br})_2$) are colored blue by addn. of acetoxime. The reaction is very sensitive. It is impossible to isolate a compd. of definite compn. The soln. in $(\text{CH}_2\text{Br})_2$ probably contains an additive compd. of 1 mol. CoCl_2 and 2 mols. acetoxime. CoI_2 reacts with acetoxime with formation of $2\text{Me}_2\text{C} \cdot \text{NOH} \cdot \text{CoI}_2 + \frac{1}{2} \text{Me}_2\text{CO}$. CoBr_2 gives a similar compd. Another type of Co compds. corresponding to $\text{Co}(\text{I}, \text{Me}_2\text{C} \cdot \text{NO})_2$ also was obtained. NiI_2 gives additive compds. contg. 2-3 mols. of acetoxime. Cu^{II} halides are reduced by acetoxime with simultaneous formation of compds. of the type $2\text{Me}_2\text{C} \cdot \text{NOH} \cdot 2\text{CuX}$. It was possible, however, to obtain $\text{Me}_2\text{C} \cdot \text{NOH} \cdot \text{CuCl}_2$. With Cu acetate $\text{Me}_2\text{C} \cdot \text{NOH} \cdot \text{Ac}_2$ was obtained. CuCl_2 reacts with acetophenone oxime to form a mixt. of additive compds. with 1 and 2 mols., resp.; it gives with benzophenone oxime $\text{Ph}_2\text{C} \cdot \text{NOH} \cdot \text{CuCl}_2$. The oximes are also capable of formation of salt-like compds. with Co, Cu and Ni.

EMIL KLARMANN

Contributions to the study of the constitution of double salts. XV. The double amines of the class of the iodides. G. SPACU and O. VOICU. Univ. of Cluj. *Bull. soc. stiint. Cluj* 4, 42-56(1928), cf. C. A. 22, 2334.—Their properties and the case with which they are formed make the amines of double salts valuable in detg. the formula for the original double salts. The following new amines have been prepd., their properties studied and the formulas of the original salts deduced: Treatment of the anhyd. $\text{ZnI}_2 \cdot (\text{NH}_4\text{I})_2$ (I) with a benzene soln. of pyridine (Py) gives after several days (in the absence of light) an unstable yellow ppt., the analysis of which corresponds to the dipyridine Zn complex, $[\text{Zn}^{\text{I}_4}_{\text{Py}}](\text{NH}_4)_2$. The salt is quickly hydrolyzed in the presence of H_2O . Addn. of dry $\text{ZnI}_2 \cdot 2\text{NaI} \cdot 3\text{H}_2\text{O}$ (II) to a soln. of aniline (An) in benzene produces after 5-6 days a rather stable white ppt., the formula of which corresponds to the dianiline Zn salt, $[\text{Zn} \text{An}_2] \left[\text{NaI} \right]^{\text{I}_2}_2$. These results show that the formulas of I and II are, resp., $(\text{NH}_4)_2\text{ZnI}_4$ and either $[\text{Zn} (\text{H}_2\text{O})_2] \text{Na}_2 \cdot \text{H}_2\text{O}$ or $[\text{Zn} (\text{H}_2\text{O})_2] \left[\text{NaI} \right]^{\text{I}_3}_2 \cdot \text{H}_2\text{O}$. $\text{PbI}_2 \cdot \text{KI} \cdot 2\text{H}_2\text{O}$ (III) is transformed into the light yellow triammine, $[\text{Pb}^{\text{I}_3}_{(\text{NH}_3)_3}] \text{K}$, in which the Pb is coordinatively satd., by passing a current of dry NH_3 over it. The ammine loses NH_3 on exposure to air and becomes dark yellow. In H_2O it decomposes with sepn. of PbI_2 . Attempts to prep. the aniline and pyridine analogs were unsuccessful. The authors conclude that the formula of III is either $[\text{Pb}^{\text{I}_3}_{(\text{H}_2\text{O})_2}] \text{K}$ or $[\text{Pb}^{\text{I}_3}_{\text{H}_2\text{O}}] \text{K} \cdot \text{H}_2\text{O}$. The addn. of $\text{CdI}_2 \cdot \text{BaI}_2 \cdot 5\text{H}_2\text{O}$ (IV) to a soln. of aniline in benzene gives after 4 days a white ppt., which decomposes in the light and the analysis of which corresponds to the diaquodaniline complex, $\text{CdI}_2 \cdot [\text{Ba}^{\text{An}_2}_{(\text{H}_2\text{O})_2}]$. Attempts to prep. the corresponding amines with NH_3 and pyridine were unsuccessful. With NH_3 IV breaks up and takes on 14 mols. of the gas, of which 8 are held by the BaI_2 and 6 by CdI_2 . The formula for IV is $\text{CdI}_4 [\text{Ba} (\text{H}_2\text{O})_4] \cdot \text{H}_2\text{O}$. On addn. of small proportions of $\text{HgI}_2 \cdot \text{CuI}$ (V) to anhyd. pyridine a green soln. forms which gives a light green ppt. when a little benzene is added. The color and analysis of this corresponds to the pentapyridine complex, $[\text{Hg}^{\text{I}_5}_{\text{Py}}] \text{CuPy}_4$. The formula is supported by the fact that the compd. loses a mol. of pyridine on exposure to air and

forms the dark green *tetrapyridine complex*. The formula for V, therefore, is HgI_2Cu . The conclusion previously stated that, in general, double salts in the solid state are really complex compds. is supported by these results. XVI. The amines corresponding to the double salts of the class of the bromides. G. SPACU AND J. DICK. *Ibid* 84-103.—The following new amines were prepd. from the hexabromostannates of the heavy metals, $\text{SnBr}_6\text{Me}^{\prime}n\text{H}_2\text{O}$ (I), where $\text{Me}^{\prime} = \text{Mn, Ni and Co}$ and $n = 6, 8$ and 10, resp., for these metals: The anhyd. hexaurotropinehexabromostannates of Mn Ni and Co, $[\text{SnBr}_6]_4[\text{Me}^{\prime}\text{Urtpr}]_6$ (II) were prepd. by adding a soln. of I in abs. alc. to a similar soln. of urotropine (Urtpr) and filtering off the resulting ppt. after about 5 min. The hydrates (III) corresponding to these (Mn, 2 H_2O , Ni, 2 H_2O ; Co, 4 H_2O) were prepd. by the same method with 95% alc. as the solvent. In order to prevent hydrolysis the pptd. amines were removed from the mother liquor immediately after formation. If the ppts. of III were allowed to stand in contact with the soln. for 15-20 min. they were partially hydrolyzed while simultaneously a mol. of urotropine was replaced by H_2O . In this way $[\text{Sn}^{\text{Br}_6}(\text{OH})]_4[\text{Mn}^{\text{Utrpr}_6}(\text{H}_2\text{O})]_6 \cdot 4\text{H}_2\text{O}$ (IV) was isolated. The anhyd. hexapyridinehexabromostannates of Mn and Co, $\text{SnBr}_6\text{Me}^{\prime}\text{Py}_6$ (V) were obtained by triturating I in a soln. of pyridine in abs. ether. The anhyd. complex Ni ammine could not be obtained in this way. However, the hexapyridine monohydroxypentabromostannate of Ni (VI) and hexapyridine dihydroxypentabromostannate of Ni (VII) were obtained by adding a soln. of I in abs. alc. to a soln. of pyridine in MeOH and then pptg. the complexes, after the hydrolysis had begun, by adding abs. ether. In this case the hydrolysis is due to the H_2O liberated in the substitution of the base. The compds. contg. urotropine are cryst. substances, stable in air. They are hydrolyzed by H_2O and by acids. The pyridine compds. are unstable. They are hygroscopic and lose pyridine in the air. The color of all the complexes depends on the nature of the metallic element contd. in the mol. Attempts to prep. the amines with aniline, ethylenediamine and toluidine were unsuccessful. Conclusions. (a) The H_2O held in the mols of I exists in 2 categories; viz., that which is held by the heavy metal, called H_2O of constitution, and that which compensates for the difference in vol. of the electronegative and electropositive parts of the mol., called H_2O of crystn. (b) The mols of the H_2O of constitution, which coordinatively sats. the metal, may be replaced by mols. of certain bases. The no. of mols. remains the same in all cases. The no. of mols. of H_2O of crystn. depends upon the nature of the heavy metal and varies directly with the at. vol. thereof. (c) The formula for I is $\text{SnBr}_6\text{M}^{\prime}(\text{H}_2\text{O})_6m\text{H}_2\text{O}$, where $m = 0, 2$ and 4, resp., for Mn, Ni and Co. XVII. The amines corresponding to the double salts of the class of the bromides. *Ibid* 110-24.—By treating solns. of the double salts, $\text{SnBr}_6\text{M}^{\prime}(\text{H}_2\text{O})_6m\text{H}_2\text{O}$ (I) (where $\text{M}^{\prime} = \text{Mn, Ni and Co}$ and $m = 0, 2$ and 4, resp., for these metals) in anhyd. acetone with a similar soln. of piperazine (Ppz), the mols of H_2O of constitution were substituted by mols of the base. Since the solvent in this case was not a dehydrating agent, the resulting complexes always contained H_2O of crystn. Inasmuch as piperazine is a bivalent base the compds. first produced have 2 mols of H_2O substituted by 1 mol. of the base. In this way the tri-piperazinehexabromostannates of Mn, Co and Ni, $\text{SnBr}_6\text{MnPPz}_3 \cdot 6\text{H}_2\text{O}$, $\text{SnBr}_6\text{NiPPz}_3 \cdot 8\text{H}_2\text{O}$, and $\text{SnBr}_6\text{MnPPz}_3 \cdot 8\text{H}_2\text{O}$ (II) were obtained. By increasing the proportion of piperazine in the reaction and by allowing a greater time for the reaction, the tetra- and hexapiperazinehexabromostannates of Mn, Ni and Co (III) were obtained. The no. of mols. of H_2O of crystn. are the same as in the mols of the triamines. All of the amines are stable in air, sol in H_2O and acids with hydrolysis and insol in the usual org. solvents. Their colors depend upon the nature of the metallic element in the complex and do not differ greatly as the no. of mols of piperazine is changed. H. F. JOHNSTON

Chemistry of the silicates. A. ENDREÉDY. Univ. of Budapest and Geol. Anstalt, Hungary. *Földtani Közlemény* 57, 105-12 (1927).—Garnet is fractionally dissolved in HCl; the process seems to indicate an orthosilicate mol. This constitution is in opposition with the thermic decompn. of garnet. An essay to replace HCl by org. acids failed. The same study was repeated with aq. chromic acid; it gave the constitution of garnet as $3\text{CaO} \cdot \text{Fe}_2\text{O}_3 \cdot 3\text{SiO}_2 = \text{Ca}_3\text{Fe}_2(\text{SiO}_4)_3$, or $14\text{CaO} \cdot 5\text{Fe}_2\text{O}_3 \cdot 14\text{SiO}_2$. A. L. H.

The preparation of ammoniacal silver solution by impregnation methods. B. J. DEKUN. Med. Inst. Kiew. *Z. wiss. Mikroskopie* 43, 382-4 (1926); *Chem. Zentr.* 1927, I, 327-8.—A criticism of earlier methods. Absolutely clean app. and pure reagents (AgNO_3 , aq. NH_3 and NaOH) are essential. Forty % NaOH is added dropwise to 10% AgNO_3 until no more ppt. is formed, the soln. is decanted, the ppt. washed with water until phenolphthalein soln. no longer gives evidence of OH ions, and finally the ppt. is dissolved in the least possible aq. NH_3 . C. C. DAVIS

Proof of the existence of ferrous chloride hexahydrate. G. AGDE AND FR. SCHIMMEL. *Z. anorg. allgem. Chem.* 173, 111-4(1928).—If a soln. of FeCl_2 satd. at 10° is cooled until crystn. occurs, then filtered at low temp. and the crystals are dried in a refrigerator, analysis indicates the compn. $\text{FeCl}_2 \cdot 6\text{H}_2\text{O}$. The soly. curve is detd. and indicated decompn. into the tetrahydrate at 12.3° .

H. STÖBERTZ

The preparation of chemically pure chromic anhydride. A. V. RAKOVSKIĬ. *J. Russ. Phys.-Chem. Soc.* 60, 13-7(1928).—The method of Zittnaw (*Pogg. Ann.* 143, 468 (1871)) gave a 50-60% yield of chem. pure CrO_3 . Larger yields (81%), though not always as pure, were obtained from $\text{Na}_2\text{Cr}_2\text{O}_7$ by treatment with Ca(OH)_2 and CaCl_2 , decompn. of CaCrO_4 with H_2SO_4 and fractional crystn. Technical CrO_3 is best obtained from $\text{Na}_2\text{Cr}_2\text{O}_7$.

BASIL C. SOYENKOFF

The preparation of hydrobromic acid in the presence of charcoal. V. N. BOZHOVSKIĬ AND P. P. DANILCHENKO. *J. Russ. Phys.-Chem. Soc.* 59, 851-8(1927).—The reaction between H_2O and Br_2 at room temp. in the presence of activated charcoal depends on the adsorption of Br_2 and reaches equil. before the whole of Br_2 is used up. It proceeds to completion if HBr is removed by the addn. of CaCO_3 . At high temps. neither HOBr nor HBrO_2 exists; the reaction is $\text{Br}_2 + \text{H}_2\text{O} \rightleftharpoons 2\text{HBr} + \text{O}$, the necessary energy being derived from the oxidation of C. A quartz tube (or one of Fe lined with asbestos) was charged with Br-treated charcoal, steam passed through for 1 hr. and then a current of Br started. The concn. of HBr can be varied with the stream of Br_2 . The yields increase with temp, reaching 97-100% at 500° . The amt. of CO_2 is max. at 500° , decreasing again at 800° . The method is cheap and capable of an industrial application.

BASIL C. SOYENKOFF

The action of iron, cobalt and nickel carbonates on benzal chloride. I. I. VANIN AND A. A. CHERNOYAROVA. *J. Russ. Phys.-Chem. Soc.* 59, 891-4(1927).— PhCHCl_2 , after 3 hrs. at $120-60^\circ$ with an excess of NiCO_3 , gives 70.6% BzH . A 70.1% yield is obtained with CoCO_3 at 60° for 3 hrs., while with Fe carbonate at the same temp. a violent reaction takes place, leaving a charred residue. The activities of the 3 metals thus follow their order in the periodic table.

BASIL C. SOYENKOFF

Colloidal barium sulfate. W. A. LOTT. *J. Am. Pharm. Assoc.* 17, 454-6(1928).—Three methods of prepn. were tried. In each a cold soln. of H_2SO_4 in EtOH was added to a cold soln. of a Ba salt. The best results were obtained with $(\text{AcO})_2\text{Ba}$ as follows. Sixty g. of $\text{Ba(OH)}_2 \cdot 8\text{H}_2\text{O}$ were moistened with H_2O to form a paste. Glacial $\text{C}_2\text{H}_5\text{O}_4$ was added to neutrality and the concd. soln. cooled to 65° . A mixt. of 16.2 g. of H_2SO_4 and 65 g. of EtOH was cooled to 0° . The H_2SO_4 soln. was added with stirring to the Ba soln. and the mixt. dried in a vacuum desiccator at 60° .

L. E. WARREN

Critical study of the notation used for the mercurammonium salts. MAURICE FRANCOIS. *Ann. chim.* 8, 341-62(1927).—The ammoniated compds. of Hg, which still have some H linked to N, give compds. of the general type Hg_2NX when they are treated with NH_4OH , KOH , NaOH or even H_2O . Rammelsberg (*J. prakt. Chem.* 38, 558 (1888)) and Pesci (*Gazz. chim. ital.* 20, 485(1890)) believe that compds. of the type Hg_2Ni pre-exist in the mols., because they appear instantaneously after treatment with KOH . This opinion has been widely accepted in France [though not in other countries] and regarded as a rule. It is grossly misleading. Their process to count the number of NH_4X groups to be added to the Hg_2NX group in order to complete the mol. is thus worthless. $\text{HgI}_2 \cdot 2\text{NH}_3$ is beyond doubt a mol. combination of HgI_2 and NH_3 gas; the same is probably true of $\text{HgBr}_2 \cdot 2\text{NH}_3$ and $\text{HgCl}_2 \cdot 2\text{NH}_3$. The ammonium theory (as outlined in Wurtz's dictionary and modified by Hofman and Marburg (*Ann.* 305, 191(1899))) is sufficient to explain the formulas of all the ammoniated compds. of Hg, including compds. like HgH_2NI .

A. L. HENNE

Black nickel oxide. Observations to the conclusions of Gulbrand Lunde concerning nickel oxides. M. LEBLANC AND H. SACHSE. *Z. anorg. allgem. Chem.* 168, 15-16 (1927); cf. Lunde (*C. A.* 22, 2521).—Pure NiO_2 prepd., at high temp., has never been obtained or even characterized with accuracy. The Ni_2O_3 prepd. by L. was probably a system comprising NiO , active O and H_2O with possibly a max. of 10% of a higher Ni oxide.

A. L. HENNE

Black nickel oxide. GULBRAND LUNDE. *Z. anorg. allgem. Chem.* 169, 405-6 (1928).—Polemical with LeBlanc and Sachse (cf. preceding abstr.). LeB. and S. had overlooked a previous article of L. (*Skrifter Norske Videnskaps-Akad. Oslo. I. Matemat.-Natur.-Klasse* 1, 536-7(1925)).

A. FLEISCHER

Production of tenorite, specular hematite and crystallized CoO (DUBOIN) 8.

7—ANALYTICAL CHEMISTRY

WILLIAM T. HALL

Theory of certain electrometric and conductimetric titrations. Correction. E. D. EASTMAN. *J. Am. Chem. Soc.* 50, 418(1928); cf. *C. A.* 19, 945. E. H.

Interpretation of the reactions of oxidation and of reduction in analytical chemistry by the electronic theory. L. DUPARC, E. ROGOVINE AND P. WENGER. *Helv. Chim. Acta* 11, 577-83(1928).—The ideas of Otis Coe Johnson published in 1883 and later expressed in terms of the electron theory by K. G. Falk some 16 years ago are explained as if they were new. W. T. H.

Electrometric titrations with a retarded auxiliary electrode. ERICH MÜLLER. *Z. physik. Chem.* 135, 102-6(1928).—If 2 similar electrodes are immersed in a soln. which is being titrated and the arrangement is such that diffusion of soln. around one electrode is prevented so that the concn. there is kept different from the concn. of reacting substance around the other electrode, a current will flow between the 2 electrodes and the max. e. m. f. will be reached at the end point. Such an arrangement can be accomplished by placing one of the electrodes in a T-tube, of which the opposite end is drawn out into a capillary and the third arm is sealed with rubber tubing through which the soln. in the T-tube can be withdrawn by suction. With such an electrode, the soln. has to be changed several times during a titration. This inconvenience can be overcome by placing one electrode (a fine Pt wire) in a capillary tube holding about 0.03 cc. of soln. The other electrode can be wound around this capillary tube. The soln. in the capillary will not diffuse out to any extent during a titration and the vol. of soln. in it is so small that it can be neglected. W. T. H.

Application of the quinhydrone electrode in electrometric titrations. II. ADOLPH I. RABINOVICH AND V. A. KARGIN. *Z. Elektrochem.* 34, 311-6(1928).—The discrepancy between the results obtained in titrating a weak acid with the quinhydrone electrode and the values as obtained with the H₂ electrode can be explained by the effect of the CO₂ in the air. In fact, the difficulty can be overcome by bubbling N₂ or other inert gas, through the soln. This introduces a complication which lessens the desirability of using the quinhydrone electrode. Kolthoff and Bosch have thought that the trouble was due to an acid impurity in the quinhydrone but this cannot be so in the work here described, as special precautions were taken with respect to the purification of the quinhydrone. The 2 max. of $\Delta E/\Delta V$ observed by MacInnis were reproduced and it was proved that the second max. was caused by CO₂. The observed displacement of the first max. can be produced by adding another weak acid such as alloxan. W. T. H.

Ceric salt as oxidizing agent in electrometric titrations. II. I. A. ATANASIU AND V. STEFANESCU. *Ber.* 61B, 1343-7(1928).—Ce salts have an advantage over KMnO₄ as oxidizing agent with respect to the facts that the solns. are more stable and the reactions of oxidation are not influenced much by changes in temp. or H-ion concn. Ce(SO₄)₂ soln., easily prepd. by electrolytic oxidation of the Ce⁺⁺—Ce⁺⁺⁺ soln. or by dissolving CeO₂ in concd. H₂SO₄, has not been used much in the past as oxidizer because the end point is not easy to recognize if one depends upon the change in color of the soln. (yellow to colorless). This difficulty disappears if the end point is detd. potentiometrically. In this paper titrations made with 0.1-0.01 N Ce(SO₄)₂ are described with HNO₂, H₂C₂O₄, H₄Fe(CN)₆, H₂O₂, Fe⁺⁺, As⁺⁺⁺, Sn⁺⁺ and Ti⁺⁺⁺. W. T. H.

The use of a cathode of dropping mercury in chemical analysis. EDMOND BAYLE AND LUCIEN AMY. *Compt. rend.* 186, 1610-2(1928).—The current produced by the dropping Hg is likely to give rise to oscillations which make accurate work difficult. This trouble has been overcome by replacing the capillary from which the Hg drops by a fine point which permits the dropping of 4-5 cc. of Hg per min. The oscillations are so rapid that they are not noticeable. It is shown how the method can be used for the detn. of small quantities of elements in the presence of considerable quantities of other cations, the strength of the current being dependent on the concn. and unaffected by less electropositive ions. Thus small amts. of Bi or Pb can be detd. in the presence of H₂SO₄ and Sb can be detd. in the presence of considerable Pb. W. T. H.

Stable thiosulfate solution. L. W. WINKLER. *Pharm. Zentralhalle* **69**, 369-71 (1928).—The addn. of 0.1 g. of $\text{Hg}(\text{CN})_2$ per l. to 0.1 and 0.01 *N* solns. of $\text{Na}_2\text{S}_2\text{O}_3$ serves to stabilize this reagent by keeping the solns. sterile. W. O. E.

Hypophosphoric acid. W. D. TREADWELL AND GEROLD SCHWARZENBACH. *Helv. chim. Acta* **11**, 405-16(1928).—A good method for the detn. of hypophosphoric acid (I) was found to be titration with UO_2SO_4 in H_2SO_4 soln. (not more than *N*) in an atm. of CO_2 with electrometric detn. of the endpoint. From the neutralization curve of I can be detd. accurately its last 3 ionization const.; for the first const. only the order of magnitude can be estd. $K'_1 \geq (10^{-2.2})$; $K'_2 = 10^{-2.81}$; $K'_3 = 10^{-7.27}$; $K'_4 = 10^{-10.02}$. The ionization const. indicate a sym. constitution for I. LOUISE KELLEY

The titration of phosphoric acid in the presence of boric acid by means of the citrate method. W. M. DEERNS. Rijksinstituut voor Chem., microbiol. en Hydrogr. Birscheljongerzoek, Helder, Netherlands. *Chem. Weekblad* **25**, 268-71(1928).—When H_3PO_4 and HBO_3 are titrated by the citrate method, the color change indicating the end of the phosphate detn. is not sharp, especially in the presence of a large quantity of HBO_3 and citrate. The amt. of indicator is likely to influence the end point. A mixt. of primary phosphate, boric acid and citrate reaches equil. very slowly.

A. L. HENNE

New indicator for the volumetric determination of phosphoric acid. L. DUPARC AND E. ROGOVINE. *Helv. Chim. Acta* **11**, 598-9(1928).—When Na salicylate soln. comes in contact with $\text{UO}_2(\text{OAc})_2$ soln., an intense orange color is produced. Expts. with aspirin and with salol show that the cause of the coloration is the phenolic and not the carboxylic group of salicylic acid. The reaction is sufficiently sensitive so that it can be used to det. the end point in the titration of H_3PO_4 with $\text{UO}_2(\text{OAc})_2$. The expts. were successful with dil. solus. so that it was possible to adapt the method to the analysis of urine. To buffer the HNO_3 soln. it is necessary to use Na salicylate instead of acetate. W. T. H.

Analysis of lead arsenates of various brands. A. A. RAMSAY. *Agr. Gaz. N. S. Wales* **38**, 945-8(1927).—Nine samples of com. Pb arsenate pastes and powders contained 62.85 to 65.73% PbO and 30.80 to 33.05% As_2O_3 , both on the dry basis, the content of PbHAsO_4 varying from 80.97 to 100% and of $\text{Pb}(\text{AsO}_4)_2$ from 0 to 22.94%. Comparison of these results with analyses of samples of the same brands obtained in 1910 showed an av. increase of 49% in the total As content, due in part to higher content of PbHAsO_4 in the 1927 samples. K. D. JACOB

Microtitration of lead cations and of chromate anions by a centrifugo-volumetric method. ROBERT F. LE GUYON AND ROGER F. AURIOL. *Compt. rend.* **186**, 1551-3 (1928).—Successful titrations of Pb^{++} with CrO_4^{--} and *vice-versa* were made with 0.5-10.0 cc. of 0.1 *N*, 0.02 *N* and 0.01 *N* solns., the end point being detd. by the failure to obtain a ppt. on adding an additional drop of reagent after centrifuging or by the appearance of a yellow color in the soln. W. T. H.

Analysis of silicate by fusion with alkaline hydroxide in a nickel crucible. C. J. VAN NIEUWENBURG AND H. H. DINGEMAUS. Technische Hoogeschool, Delft, Netherlands. *Chem. Weekblad* **25**, 266-8(1928).—The decompn. of a no. of technical silicates can be successfully accomplished by molten KOH or NaOH at about 400° in a Ni crucible. Besides economizing on expensive Pt crucibles, this procedure has the advantage of permitting the digestion of the fusion product with H_2O in the crucible itself. The time of contact between the alk. soln. and glass or porcelain is reduced. Direct contact between the flame and the Ni crucible must be prevented; then the crucible will last a practically unlimited no. of times. The degree of completeness of the decompn. has been measured with some glasses, porcelain, orthoclase, china clay, orthite and some samples of fire-clay brick. It proves to be of the same order of magnitude as with molten Na_2CO_3 , *e. g.*, about 99.5%. A. L. HENNE

The use of α -hydroxyquinoline for the chemical analysis of silicates. JOS. ROBERT-SCHERK. *J. Am. Ceram. Soc.* **11**, 587-94(1928).—A method devised by Berg for the detn. of different metals (cf. C. A. **21**, 1237, 1778, 2449, 2630, 3849, 3850) is used for silicates. Al_2O_3 and MgO are pptd. with α -hydroxyquinoline and the ppts. can be either dried and weighed or dissolved and titrated. Both can be detd. in the presence of SiO_2 , thus saving time, if the detn. of SiO_2 is not required. Details are given; also for the detn. of alkalis. C. H. KERR

The estimation of potassium as potassium chloroplatinate. MARGARET MCCURDY. Dalhousie Univ., Halifax, N. S. *Proc. Trans. Nova Scotian Inst. Sci.* **16**, 142-3(1928).—After Na_2PtCl_6 has been removed from K_2PtCl_6 with alc., it is more convenient to ignite the latter at a high temp. (Fischer burner) and from the weight of Pt, calc. the amt. of K, than to dry K_2PtCl_6 to const. wt. There is no loss in accuracy. A. L. H.

The analytical valuation of technical casein. FRITZ BAUM. *Chem.-Ztg.* **52**, 517-8(1928).—A discussion of methods proposed for the testing of com. casein. Analyses of 4 samples are given. W. T. H.

The evaluation of barium hydroxide, $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$. ED. V. DRATHEN. *Chem.-Ztg.* **52**, 518(1928).—Samples of $\text{Ba}(\text{OH})_2$ were dissolved in CO_2 -free water, the solns. filtered and titrated with 0.2 N HCl, H_2SO_4 and $\text{H}_2\text{C}_2\text{O}_4$, phenolphthalein being used as indicator. Correct results were obtained with HCl alone. Apparently there is absorption of alkali by ppts of BaSO_4 or BaC_2O_4 corresponding to about 2% of the total alkali present. W. T. H.

New method for determining water by distillation with xylene and tetrachloroethane. KURT SCHAEFER. *Chem.-Ztg.* **52**, 408(1928).—A new construction of the app recommended by S. in 1924 is shown. The distg. flask which serves to hold the excess reagent is provided with a ground-glass stopper connecting with a condenser at the top of which is a siphon tube which carries the excess reagent back to the flask through another tube leading through the ground-glass stopper. In the condenser is a measuring tube which is filled with xylene or tetrachloroethane at the start. During the expt. the water collects in this tube, replacing the reagent. When tetrachloroethane is used, which has the advantage of not being combustible, a slight change in the construction of the app. is necessary. W. T. H.

Modification of the pyrogallol method for determining the amount of oxygen in air. L. A. MUNROE. Univ. of Manitoba. *J. Chem. Education* **5**, 741-2(1928).—The app. recommended consists of a test tube fitted with a 2-holed rubber stopper. Through one hole connection is made with a leveling bulb contg. alk. pyrogallol. The bulb carries at the top a cork stopper with a small perforation so that air does not enter and leave the bulb as readily as if it were left open. With the pyrogallol soln level with the upper surface of the stopper in the test tube, a glass is inserted in the other hole of its stopper and the pyrogallol is forced up into the tube by lowering the test tube. W. T. H.

Helium studies. I. Method for the detection of small quantities of helium. FRITZ PANETH AND KURT PETERS. *Z. physik. Chem.* **134**, 353-73(1928). Kirchhoff and Bunsen, in their classic spectroscopic researches, estd 3×10^{-10} g as the limit of detectability of Na. They had in mind what Eimich has called the *theoretical* sensitivity of the spectroscopic method for detecting Na because in their work K. and B. always had more Na present. As a rule the *practical* sensitivity, or the smallest quantity which can actually be worked with and detected, is usually 10 or 100 times as great. Lord Rayleigh (Strutt) succeeded in detecting He when only 5×10^{-7} cc was present and in detecting Ne at about half this concn. The present writers, however, by taking pains to overcome several sources of error have succeeded in refining the work with the spectroscope so that 10^{-10} cc of either He or Ne can be detected. They have made the practical sensitivity coincide with the theoretical sensitivity. The presence of Ne can be detected in 10^{-4} cc of air. With the method now described it is possible to detect the evolution of He from the invisible active ppt of Th; in this case the γ -activity of Th B and Th C in radioactive equil must be equiv. to only 0.1 mg of Ra. In order to obtain this precision it is necessary to free the gas under examn. from all constituents other than Ne and He. This is accomplished for gases other than H_2 by absorption with charcoal chilled by liquid air. With H_2 , the method of exploding with O_2 is of course permissible, the excess O_2 being removed by cold charcoal but it is better to effect the combustion with a catalyzer preferably Pd sponge. Larger quantities of H_2 can be removed more readily by means of Ca filings. The method when carried out with the greatest precision, requires attention to a great many details concerning which the original paper must be consulted. An interesting table is given of some 33 wave lengths showing the concn. at which the different spectral lines of He and Ne can be identified. W. T. H.

The influence of some of the elements in iron on the oxygen determination by the hydrogen reduction method. P. BARDENHEUER AND CHR. A. MÜLLER. *Arch. Eisenhüttenwesen* **1**, 707-12(1927-8), *Stahl u. Eisen* **48**, 795(1928).—The effect of N, P and S on the detn. of O in steel was investigated. During the detn. of O by the H reduction method volatile N-HI compds are formed, which are possibly retained in the U-tubes by the P_2O_5 and erroneously calcd as O. In 8 samples of an acid-Bessemer steel with 0.0203% N, the O was detd. by the H reduction method and found to be 0.003%. Next the N remaining in the samples and absorbed by the P_2O_5 in the U-tubes was detd. The av. decrease of the N content of the samples was 28%; the amt. of N absorbed by the tubes, on the other hand, was negligible. Expts. with nitrized samples disclosed the fact, that while the total N content of the samples escaped, only 0.75-0.95% of the

N present in the samples was absorbed by the P_2O_5 tubes. If, however, the O detn. was carried out without the addn. of Sb, 15.62–18.45% of the N present was absorbed by the P_2O_5 tubes, which shows that the usual addn. of Sb minimizes the effect of N. In order to investigate the effect of P, 10 g. Sb, 0.06 g. MnO and 0.1 g. of Fe-P contg. 21.1% P were added to 10 g. of electrolytic Fe and then the O was detd.; only 73% of the O of the MnO was obtained as H_2O . The distribution of P was more uniform, the same as it is in steel, in the 2 following tests: to samples with 0.154 and 0.240% P, 0.06% MnO was added and the O content detd. With 0.154% P, 59% of the O of MnO was obtained as H_2O , with 0.240% P only 47%. The effect of S was investigated in the same way. To samples with 0.270 and 0.115% S 0.06% MnO was added; with 0.270% S 80%, with 0.115% S 95% of the O of the MnO was obtained as H_2O . The N and S contents of steels do not influence the O detn. by the H reduction method; the P content however causes considerable differences in the results of the O detn. J. A. SZILARD

The Bunsen method for analyzing pyrolusite, etc. E. RUPP. *Chem.-Ztg.* **43**, 429–30 (1928).—Directions are given for constructing a suitable app. from materials available in every lab. Place 2.5 g. of KI in a stout 750-cc. bottle carrying a 2-holed rubber stopper. Through one hole a $CaCl_2$ drying tube is inserted and through the other hole the gas enters from the distg. flask. Dissolve the KI in 250–300 cc. of water. Place about 4 milli-equiv. of the oxide in a distg. flask with a 30 cc. bulb and treat it with 25 cc. of concd. HCl. (It is best to introduce the substance in a small glass vessel so that no powder touches the sides of the flask.) Distil over half of the acid, using a small flame protected from drafts. In order to protect the KI soln. from sucking back into the flask, and herein lies the special feature of the app., the distn. tube of the flask is cut off, leaving about 5 cm., and this short tube is bent so that it feeds into the large bottle with the latter upright and the distg. flask inclined at about 45° . This short tube is connected with a tube, 18–20 cm. long, leading to the bottom of the bottle contg. the KI soln. The tube is a capillary of 2.5–2.8 mm. internal bore. It is also well to insert in the neck of the distg. flask a tube with rubber tubing at the top and a pinch-cock, as in a vacuum distn. To reduce the expense, a mixt. of 1 g. KI and 2 g. of KBr can be used instead of the 2.5 g. of KI. Or, the KI can be replaced altogether by 0.1 N arsenite soln., in which case an open beaker can be used as receiver. Good results can also be obtained by using an alk. soln. of KI so that NaI or $NaIO_3$ is formed and after the evolved Cl_2 has all been absorbed, an equiv. amt. of I_2 is liberated upon the addition of acid. W. T. H.

Simple detection of cobalt in cobalt steels. JAMES MOIR. *J. S. African Chem. Inst.* **11**, 33 (1928).—Dissolve enough of the sample to yield at least 0.1 mg. of Co in aqua regia and exam. the soln. with the spectroscope using a wide slit. With considerable Co, the red end of the spectrum is cut off entirely and 2 narrow absorption bands (γ 621 and γ 607) are visible in the orange area. With little Co, the 2 bands in the orange are not seen but towards the red end a very deep band appears at γ 700 and a fairly deep band at γ 661. With high Co these bands can be obtained by dilg. the soln. with concd. HCl soln. (not H_2O). 0.0002 g. (10 mg. of steel with 2% Co) Co is easily detected by this method when dissolved in 8 cc. of aqua regia. W. T. H.

Vanadium in chrome-vanadium-tungsten steels. Volumetric determination. H. H. WILLARD AND PHILENA YOUNG. Univ. of Michigan. *Ind. Eng. Chem.* **20**, 764–8 (1928).—V can be oxidized in the presence of W, Cr, Mo and Fe by $KBrO_3$ in a soln. contg. NH_4 salt and a definite concn. of HCl. The excess bromate can be removed by boiling and the vanadic acid titrated electrometrically with $FeSO_4$ soln. The end point can also be detd. by the use of diphenylbenzidine as internal indicator which gives a purple color with vanadic acid. In this case, however, it is necessary to remove all H_2WO_4 which prevents the formation of the color. A correction must be applied when diphenylbenzidine is used for the amt. of HVO_3 reduced by the indicator and the small quantity of V carried down by the WO_3 should be estd. by dissolving the ppt. in 4% NaOH soln. and comparing the color of the soln. with that of a known quantity of vanadotungstic acid. W. T. H.

Persulfate method for chromium plus vanadium in chrome-vanadium-tungsten steels. Modified procedures. H. H. WILLARD AND PHILENA YOUNG. Univ. of Mich. *Ind. Eng. Chem.* **20**, 764–8 (1928).—In the persulfate method for the detn. of V and Cr in steel it has been necessary in the past to remove tungsten as WO_3 from the oxidized, acid soln. of the sample. This is unfortunate because the WO_3 ppt. is likely to carry with it a little V. If, however, the ppt. of WO_3 is dissolved in 4% NaOH (not over 15 cc.) the alk. soln. can be added to the main filtrate from the WO_3 being used and there will be no pptn. of WO_3 if the acid soln. contains sufficient Fe^{+++} . It is recommended, therefore, to take 1–1.5 g. of the original steel and, after removing the WO_3 in the usual

way, to add an addnl. g. of Fe. Then on adding the soln. of WO_3 in NaOH to the main soln. there will be no pptn. and the persulfate method can be carried out as in the absence of W. The end point in the Cr and V titrations can be detd. electrometrically or diphenylbenzidine can be used as inside indicator. In that case, after the addn. of the HCl to reduce the MnO_4^- formed by the persulfate oxidation, it is necessary to reduce the acidity by adding NaOAc before introducing the indicator. W. T. H.

Microchemical determination of calcium. F. ROGOZINSKI. Cracoeire Univ. *Bull. soc. chim.* 43, 464-9(1928).—Quantities of Ca ranging from 0.27 to 1.1 mg. were detd., with accuracy as $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ by pptn. with 1 cc. of H_2SO_4 and 4 vols. of alc. in a centrifuge tube. The ppt. was dried at $100-104^\circ$. W. T. H.

The determination and colorimetric determination of traces of aluminum. I. M. KOLTHOFF. *J. Am. Pharm. Assoc.* 17, 360-1(1928)—In weakly acid solns. hydroxymethylanthraquinone is a very delicate indicator for Al, a purple color being produced. A buffer soln. consisting of 10 vols. of 5 N AcOH and 9 vols. of 5 N NH_4OH is used. To 10 cc. of soln. contg. 0.02-1.0 mg. of Al per l. 0.25-1.0 cc. of buffer solution and 0.3 cc. of 0.1% indicator in EtOH are added. After 15-30 min. the color is compared with a blank and with a standard soln. of Al. At 50° the test is decisive in 5 min. Cu salts have a disturbing effect but the difficulty may be overcome by adding an excess of $\text{Na}_2\text{S}_2\text{O}_4$. Fe, Sb Sn and Bi interfere but this may be overcome by the addn. of $\text{KNaC}_4\text{H}_4\text{O}_6$ or better $\text{Na}_2\text{C}_4\text{H}_4\text{O}_6$. The sensitivity to the reaction for Al is thereby diminished. L. E. WARREN

Titrimetric determination of aluminum. II. ALFRED WÖHLK. *Dansk Tids. Farm.* 1, 525-36(1927); cf. *C. A.* 18, 953.—To the soln. of Al^{+++} salt, add NH_4Cl and NH_4OH till basic to methyl red. Boil, allow the $\text{Al}(\text{OH})_3$ ppt. to settle and filter. Dissolve the ppt. in acid and repeat the pptn. Dissolve the washed ppt. in a measured vol. of hot, N $\text{H}_2\text{C}_2\text{O}_4$ and titrate the excess acid with N NaOH using methyl red as indicator. O. A. NELSON

Rapid method for the separation of aluminum and beryllium. I. M. KOLTHOFF AND ERNEST B. SANDELL. Univ. of Minn. *J. Am. Chem. Soc.* 50, 1900 4(1928).—Treat the soln. of Be and Al salts (contg. not more than 0.1 g. of either oxide in 100 cc.) with oxime in AcOH soln. at $50-60^\circ$. Add 2 N NH_4OAc until a permanent ppt. is obtained and then 20-25 cc. in excess. Filter, wash with cold water, dry at $120-40^\circ$ and weigh as $(\text{C}_2\text{H}_5\text{ON})_2\text{Al}$. In the filtrate ppt. Be by adding NH_4OH , filter, ignite and weigh as BeO . W. T. H.

Colorimetric determination of titanium by hydrogen dioxide. FREDERICK G. GERMUTH. *J. Am. Chem. Soc.* 50, 1910(1928).— H_2PO_4 causes a slight fading of the color characteristic of Ti^{+++} .— H_2O_2 reaction but the addition of 1 cc. of 0.1% $\text{UO}_2(\text{OAc})_2$ soln. for each mg. of Ti present counteracts this effect. W. T. H.

Adsorption of cadmium sulfide and its importance in the estimation of cadmium. HARRY B. WEISER AND EDWARD J. DURHAM. *J. Phys. Chem.* 32, 1061-4(1928).—It has been known for a long time that the ppt. produced by H_2S in HCl soln. of Cd^{++} is likely to be contaminated with chloride. Treadwell has assumed this to be caused by the formation of a double salt but it is here shown that the best explanation is that of adsorption by CdS . The adsorption was studied at 25° with varying concns. of HCl and also in a soln. kept satd. with H_2S when it cooled from 80° to 25° . All the evidence seems to be in favor of the adsorption theory. The adsorption is sufficient and so varied under slightly different conditions that it would seem that the detn. of Cd as CdS cannot be regarded as an accurate analytical method. W. T. H.

Determination of lead in gold by spectral analysis and a new method for emission spectral analysis. IV. WALTHER GERLACH AND EUGEN SCHWEITZER. *Z. anorg. allgem. Chem.* 173, 92-103(1928).—The intensity of the Pb lines tends to fall off after a short time and eventually increases and falls again. This was found due to the formation of PbO as a result of heating the electrodes. To avoid this effect it is necessary not to use over 1-1.5 ampere of primary current. In Ångström units, the Pb lines at 2614 and 3684 can be used for the detn. of Pb in Au. With 0.8% Pb the 2614 line has the same intensity as the 2544 line for Au. Some 28 Au samples with Au content ranging from 0.0027 to 0.985% Pb were analyzed by the spectrographic method, the exact details of which are given, and all of the results agreed closely with those obtained by the usual methods of chem. analysis. Another method of spectral analysis is described in which the spectrum of Sn is compared with that of $\text{Au} + x\%$ Pb, in which the Pb content is detd. by comparing the intensity of Au and Sn lines. W. T. H.

A spectroscopic method for the detection of deposition of impurities in a metal. V.

WALTHER GERLACH AND EUGEN SCHWEITZER. *Z. anorg. allgem. Chem.* **173**, 104–10 (1928).—A method of spectral analysis is described which gives data showing whether impurities are distributed uniformly or otherwise throughout the alloy. By this method it was found that in Au contg. 0.04–1.0% of Pb, the latter element was deposited, for the most part, at the grain boundaries of the Au crystals. W. T. H.

Analysis of chrome iron ore. **E. DITTLER.** *Z. angew. Chem.* **41**, 132–3 (1928).—Fusion of this ore with Na_2CO_3 is never complete, and the analysis is best carried out in the following manner. The finely ground mineral is fused with 10 times its wt. of NaOH in a Ag crucible, the melt dissolved in water, acidified with HCl, and the pptd. Ag and AgCl are removed. The filtrate, to which a few cc. of H_2O_2 have been added to reduce the Cr present, is evapd. to dryness and the silicic acid removed by evapn. with HF; the residue is decompd. with Na_2CO_3 and a little KNO_3 , and, after treatment with H_2O_2 , the combined oxides of Al, Fe and Cr are pptd. with NH_3 soln. Provided that excess of H_2O_2 is removed before pptn., all the Cr is obtained as oxide. The 3 oxides are treated with Na_2O_2 when the Fe remains as insol residue and the chromate is detd. volumetrically in the filtrate after conversion of the Mn present into MnO_2 while the Al content is obtained by difference. In the filtrate from the 3 oxides, Ca, Mg and Mn are detd. by the ordinary methods. B. C. A.

Improvements in the method used for the ultimate analysis of organic compounds. **A. WAHL AND J. P. SISLEY.** *Compt. rend.* **186**, 1555–8 (1928).—Dumas and Stas obtained excellent results in the combustion of org. substances by using 1 g. of substance and a layer of CuO about 1 m. long. With these materials, a combustion required about 8 hrs. The work of Berl and others has shown that good results can be obtained with very small quantities of substance by using a micro-balance sensitive to 0.01 mg. It is here pointed out that equally good results can be obtained with 0.08–0.10 g. of substance, a furnace 50–60 cm. long and heated by 6 burners, and with the ordinary chemical balance in 25 min. to 1 hr. When halogen is present calcined PbCrO_4 should be used instead of the CuO. The results on 16 different substances, including thiourea, which is regarded as hard to burn, were satisfactory for both H and C. W. T. H.

Note on the determination of arsenic in organic material. **A. W. ROWE.** *J. Lab. Clin. Med.* **12**, 150–3 (1926); *Physiol. Abstracts* **12**, 136.—The As is extd. by treatment with HCl, and distd. as AsCl_3 ; NH_4 arsenite is then formed, and treated with $\text{Fe}_2(\text{SO}_4)_3$. The ppt. is dissolved in HCl and the soln. treated with Zn and HCl, the resulting AsH_3 being estd. by Sanger and Black's method. H. G.

Determination of alcohols. **A. VERLEY.** *Bull. soc. chim.* **43**, 469–72 (1928).—As reagent use a mixt. of 2 parts of pyridine and 1 part of Ac_2O contg. 5% of AcCl . Carefully measure out 10 cc. of the mixt., dil. with water and det. how much NaOH is necessary to effect neutralization with phenolphthalein as indicator. To about 0.1 mol. of the alc. in a dry flask add 10 cc. of the above acetylating mixt. and heat under a reflux condenser until acetylation is complete. Rinse out the flask and titrate again with NaOH. From the loss in acidity, the amt. of AcOH used up in the acetylation reaction is easily detd. It is a measure of the amt. of alc. present. The acetylation was found to be complete in 1 hr. with butyl alc., but 4 hrs. was required with menthol and 3 hrs. with santalol and with methylphenylcarbinol. If proper precautions are taken, the results are accurate. W. T. H.

Examination of some tests for methanol. **E. W. TODD.** Dalhousie Univ., Halifax, N. S. *Proc. Trans. Nova Scotian Inst. Sci.* **16**, 147–51 (1928).—A study of the various methods for detecting EtOH shows that the fuchsine color test is the most satisfactory. A. L. HENNE

Electrometric titration of phenols in alcoholic solution. **W. D. TREADWELL AND GEROLD SCHWARZENBACH.** Zürich techn. Hochschule. *Helv. Chim. Acta* **11**, 386–405 (1928).—It is often necessary to titrate weak org. acids in alc. solns., sometimes because the acid is not very sol. in water and sometimes because the salts of the weak acids are too much hydrolyzed in aq. soln. to permit an accurate titration. The addn. of the alc., however, always exerts an effect upon the ionization of the acid. It is desirable, therefore, to know the ionization of weak acids in alc. In this paper it is shown how the ionization const. can be computed, in many cases, by the result of electrometric titration and the consts. of 26 phenolic compds. of weakly acid character were detd. In abs. alc. the following 8 ionization consts. were obtained: phenol, $10^{-12.6}$; pyrocatechol, $10^{-12.0}$; resorcinol, $10^{-12.3}$; hydroquinone, $10^{-12.8}$; *o*-nitrophenol, $10^{-12.7}$; *p*-nitrophenol, $10^{-12.1}$; picric acid, $10^{-2.7}$; 2,4-dinitrophenol, $10^{-2.0}$. In 96% alc., the following 18 ionization consts. were detd.: *p*-nitrosophenol, $10^{-8.1}$; α -nitroso- β -naphthol, $10^{-8.7}$; α -monohydroxyanthraquinone, $10^{-8.8}$; β -monohydroxyanthraquinone,

$10^{-4.7}$; 1,4-dihydroxyanthraquinone, $10^{-4.3}$; 1,8-dihydroxyanthraquinone, $10^{-4.3}$; 1,2-dihydroxyanthraquinone, $10^{-4.4}$; 1,3-dihydroxyanthraquinone, $10^{-4.3}$; 2,3-dihydroxyanthraquinone, $10^{-4.7}$; 2,6-dihydroxyanthraquinone, $10^{-4.6}$ and $10^{-7.4}$ (the only one of these isomers in which the second hydroxyl group was acidic enough to be titrated); 1,2,4-trihydroxyanthraquinone, $10^{-4.0}$; 1,2,5-trihydroxyanthraquinone, $10^{-4.7}$; 1,2,6-trihydroxyanthraquinone, $10^{-4.8}$; 1,2,7-trihydroxyanthraquinone, $10^{-4.2}$; 1,2,3-trihydroxyanthraquinone, $10^{-4.6}$; 1,2,3,4-tetrahydroxyanthraquinone, $10^{-4.1}$; eriochrome yellow G, $10^{-4.6}$; eriochrome-blue-black R, $10^{-4.6}$. With respect to these last 2 compds., the former is obtained by conjugating diazotized *m*-nitroaniline with *o*-cresotinic acid and the latter from 1-hydroxy-2-aminonaphthalene-7-sulfonic acid and β -naphthol.

W. T. H.

Gasometric determination of primary aromatic amines. A. V. PAMFILOV. *J. Chem. Ind. (Moscow)* 4, 328(1927); cf. Grigoriev, *C. A.* 21, 37.—The method described by Grigoriev for detg. primary aromatic amines has been investigated and found more complicated and less exact than the method of diazometric detn. by titration. The latter works best under conditions described by Jones and Lee (*C. A.* 18, 3022), i. e., by operating in presence of an excess of nitrate which is titrated back by *p*-nitroaniline. To prevent volatilization of HNO_2 , HNO_3 is added to the soln. which is to be analyzed.

BERNARD NELSON

A new test for acrolein. J. PRITZKER. *Helv. Chim. Acta* 11, 445(1928).—Powick (*C. A.* 18, 1580) has worked out the following test for acrolein (I): treat 3 to 4 drops of dil. aq. I with an equal quantity of 3% H_2O_2 . Allow the mixt. to stand a min. and then add 5 cc. of concd. HCl and 5 cc. of phloroglucinol in Et_2O . Shake the mixt. 1 min.; the HCl layer assumes an intensely red color. Prittker has found this test thoroughly satisfactory.

REYNOLD C. FUSON

Possible extension of Stepanov's method to the determination of halogen attached to the benzene nucleus. G. FAYREL AND BUCHER. *Ann. chim. anal. chim. appl.* 9, 321-4(1927).—Stepanov's method (*C. A.* 1, 397) has proved successful for detg. halogen in org. substances but has not given good results with halogen attached to the benzene nucleus. In nearly every case, however, the difficulty can be overcome by using twice as much Na as S. originally recommended and raising the temp. at which the decomposition takes place. The latter end can be accomplished easily by substituting isoamyl alc. for EtOH. Introduce 0.4 g. of the org. substance together with 40 g. of isoamyl alc. into a flask which is connected to a reflux condenser. Through the top of the condenser, add in 2-3 portions, 50 times the wt. of Na theoretically required to combine with the halogen present. This usually raises the temp. to about 140° . Apply heat, if necessary, to keep the reaction temp. at about this point. Then, after all the Na has dissolved, continue boiling for half an hr. Allow to cool until the alcoholate begins to sep. out, then add 100 cc. of water, make acid with HNO_3 and transfer to a separatory funnel. Drain off the lower layer of liquid, and wash the alc. layer at least twice. To the aq. soln. add 40 cc. of 0.1 *N* AgNO_3 and titrate the excess Ag by the Volhard method.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

The plastic deformation of ore minerals. M. J. BUEGGER. Mass. Inst. Techn. *Am. Mineral* 13, 1-17, 35-51 (1928).—The position of slip striations on deformed *galena* indicate that it deforms along (001) by translation. The absence of striations on cleavage faces parallel with the load, when the latter is normal to a (110) plane, gives the translation directions as (110). The deformation involves a reorientation of crystallographic directions such that a (111) direction tends to become parallel to the load. *Sphalerite* deforms by gliding on (111), the character of the movement being that of secondary twinning, not of translation. *Chalcopyrite* deforms by translation on (111). The translation direction is predicted as (110) from a consideration of the at. arrangement. Good results were not obtained on pyrrhotite. Conclusion: Very pure minerals are to be expected to deform by translation, while concd. solid soln. minerals deform by secondary twinning. The results are interpreted in terms of crystal structure.

C. B. SLAWSON

Miargyrite and tetrahedrite from the Flint district, Idaho. EARL V. SHANNON. U. S. Nat. Mus. *Am. Mineral* 13, 18-21 (1928).—The paper contains crystallographic and micrographic descriptions of these sulfides, with notes on their occurrence and paragenesis.

C. B. SLAWSON

Zirklerite. A new mineral formed by thermodynamic metamorphism from the saline stocks of Northern Germany. E. HARBORT. *Kali* 22, 157-61 (1928).—The formula of the mineral is approx. $[\text{Al}_2\text{O}_3 \cdot \text{H}_2\text{O} + 4.5 (\text{Fe}, \text{Mg}, \text{Ca}) \text{Cl}_2 \cdot 2\text{H}_2\text{O}]$. It oxidizes in the air, is uniaxial, +, and cleaves on a rhombohedron, its hardness is about 3.5, sp. gr. 2.6.

A. L. HENNE

The natural history of the silica minerals. A. F. ROGERS. Stanford Univ. *Am. Mineral* 13, 73-92 (1928).—This presidential address is an excellent critical summary of the literature to date dealing with the following modifications of SiO_2 : *opal*, *chalcedony*, *quartz*, *tridymite*, *cristobalite* and *lechatelierite*.

C. B. SLAWSON

Production of tenorite, specular hematite and crystallized cobaltous oxide. A. DUBOIS. *Compt. rend.* 186, 1133-5 (1928).—CuO was added little by little to fused KF and the mixt. was allowed to cool slowly. On extn. with water crystals of CuO were obtained. Better crystals were made by adding to the fused KF the result of a previous fusion of hydrated KF and CuO or CuCl_2 , KCl being then added and the mass kept at a red heat for 2 or 3 days, the resulting crystals being larger as the heat treatment was prolonged. Analysis gave Cu 79.85%; sp. gr. 6.3. By a similar procedure with CoCl_2 in place of CuCl_2 , crystd. CoO was obtained.

L. W. RIGGS

Occurrence of hematite at Bernece, Kom. Hont, Hungary. FR. PAPP. *Földtani Közlöny* 57, 112-7 (1927).—A description of the crystals; the hardness = 6-7; $d^{20} = 5.31$.

A. L. HENNE

Manganiferous mineral from Kara-Chaguir in Fergana. A. SAUKOV. *Compt. rend. acad. sci. U. R. S. S. [Russia]* 1926, 77-9.—The black mineral has $d \ 2.985 \pm 0.09$ and contains: Fe_2O_3 2.7, Al_2O_3 9.8, ZnO 10.4, NiO 11.8, CoO 1.4, CuO 5.41, CaO 0.08, V_2O_5 4.3, MnO_2 23.6, H_2O (−110°) 4.6, H_2O (+110°) 19.9, insol. 2.95, Mo also is present.

B. C. A.

Natural hydrated magnesia. N. S. KURNAKOV AND V. ČERNÝH. *Mem. soc. russe min.* 55, 74-95 (1926).—*Brucite* has $d \ 2.360-2.396$, $\omega \ 1.5534$, $\epsilon \ 1.5840$, $2V = 2-8^\circ$; *nonulite* has $d \ 2.310-2.397$, $2V = 18-26^\circ$. Dehydrated brucite has $\omega_D \ 1.6282$, $\epsilon_D \ 1.6192$. The + double refraction becomes − on dehydration of brucite, and again + when the dehydrated mineral remains in the air. The 2 minerals cannot be differentiated by chem. or thermal investigation.

B. C. A.

Hydrotalcite and pyroaurite. N. S. KURNAKOV AND V. ČERNÝH. *Mem. soc. russe min.* [ii], 55, 118-28 (1926).—The brucite nucleus is present in both minerals; in hydrotalcite it is assocd. with Al_2O_3 and in pyroaurite with Fe_2O_3 . CO_2 (0-10.84%) and H_2O (about 8 mols.) are also present.

B. C. A.

Data on zoned plagioclase. I. E. LENGVEL. *Földtani Közlöny* 57, 95-102 (1927).—A petrographical study.

A. L. HENNE

Larsenite and calcium-larsenite, new members of the chrysolite group, from Franklin, N. J. C. PALACHE, L. H. BAUER AND H. BERMAN. Harvard Univ. *Am. Mineral* 13, 142-4 (1928).—Larsenite, PbZnSiO_4 , occurs as slender prismatic crystals in cavities in massive ore. It is orthorhombic, white, transparent with adamantine luster and good prismatic cleavage; sp. gr. = 5.90. Optically −, $2V$ about 80° , $\rho > v$ perceptible. Optic plane lies across the elongation with an optic axis nearly normal

to the cleavage. $Y = c$, $X = a$, $\alpha = 1.92$, $\beta = 1.95$, $\gamma = 1.96$. Analysis gave: SiO_2 16.87, PbO 56.66, ZnO 22.74, FeO 0.10, MnO 0.14, CaO 2.42, MgO 0.20, H_2O 0.76%. Calcium-larsenite is more abundant and occurs massive in the walls of the veins. It is white opaque with a greasy luster and indistinct cleavage, and fluoresces lemon yellow in ultra-violet. Sp. gr. = 4.421. Optically —, $2V = 5^\circ$; $\alpha = 1.760$, $\beta = 1.770$, $\gamma = 1.774$. Some samples yield higher ns . The compn is: SiO_2 24.10, FeO 0.48, MnO 0.57, CaO 16.36, ZnO 30.61, PbO 27.63, MgO 0.23, H_2O 0.12%. C. B. SLAWSON

The oscillation method of x-ray analysis of crystals. The use of the oscillation method in determining the structure of analcite. JOHN W. GRUNER. Univ. of Minn. *Am. Mineral* 13, 123-41, 174-93(1928).—Analcite has a cubic holohedral lattice and seems to belong to the space group O_h^9 , although the data agree practically as well with the requirements of O_h^{10} , and the correct choice must await further data. The unit cube contains 16 mols. of $\text{NaAlSi}_2\text{O}_6 \cdot \text{H}_2\text{O}$. Its edge is 13.64 Å. c. long. Full details of the technic of the oscillation method are given. C. B. SLAWSON

Zeolites from Ritter Hot Spring, Grant County, Oregon. D. F. HEWETT, E. V. SHANNON AND FOREST A. GONVER. *Proc. U. S. Nat. Museum* 73, Art. 16, 1-18(1928).—Samples of diabantite, levynite, calcite and heulandite are described as to their phys. features, while mesolite, pseudomesolite, thomsonite, stilbite, analcite and chabazite are described physically, and their chem. analyses are reported. The assocn. of the zeolite-bearing areas, fault fissure and active hot spring is considered in an attempt to interpret the mineral genesis. L. W. RIGGS

Anauxite from the Ione formation of California. V. T. ALLEN. Univ. of Calif. *Am. Mineral* 13, 145-52(1928).—A micaceous mineral, for which the name *ionite* had been proposed, is identified as anauxite. It was formed by the weathering of biotite or chlorite under tropical conditions. Four new analyses and optical data are given. C. B. SLAWSON

Anauxite, a mineral species, based on material from Bilin, Czechoslovakia. C. S. ROSS AND WM. F. FOSHAG. U. S. Geol. Survey. *Am. Mineral* 13, 153-5(1928).—Analyses of 2 specimens give the formula $2\text{H}_2\text{O} \cdot \text{Al}_2\text{O}_3 \cdot 3\text{SiO}_2$. The mineral is monoclinic with vermicular crystal habit. It shows perfect basal cleavage with hexagonal cross section. Color white, $\alpha = 1.559$, $\beta = 1.564$, $\gamma = 1.565$. Extinction nearly parallel; $a = Y$, $b = Z$, $c = X$, $2V = 30-40^\circ$, $\rho > \epsilon$. It is a widely occurring clay mineral in so-called *kaolins*. C. B. SLAWSON

Origin of metal in meteorites. GEORGE P. MERRILL. *Proc. U. S. Nat. Museum* 73, Art. 21, 1-7(1928).—The relations between the metallic and silicate portions of stony meteorites as interpreted by different observers are reviewed. The questions considered are: (1) What is the source of the material and its manner of deposition? (2) Will the same explanation apply to the pallasites, particularly those of the Rokycky group, which seems applicable to the stony forms? M. considers the metal as introduced at a temp. lower than that of the m.p. of the silicates and in the form of lawrencite (FeCl_2), which is reduced, at a temp. not exceeding 400° in an atm. of H_2 , to the condition of a metallic paste in which the silicate fragments become engulfed. L. W. RIGGS

A new tungsten (scheelite) deposit at Lower Sackville, Halifax County, N. S. HARRY PIERS. Provincial Museum Halifax, N. S. *Proc. Trans. Nova Scotian Inst. Sci.* 16, 38-45(1928).—A description of a vein of scheelite (CaWO_4) recently prospected. The mineral occurred in the quartzite division of the gold measures, of lower Cambrian or possibly Pre-cambrian age. A. L. HENNE

Silica in Canada. Its occurrence, exploitation and uses. II. Western Canada. L. HEHER COLB. *Can. Dept. Mines, Mines Branch No. 686*, 56 pp.(1928).—The Beauséjour sand deposit, Black Island sandstone and 3 other deposits in Man., 2 in Sask., 3 in Alb. and 3 in B. C. are described. Over 20 chem. analyses and many granulometric analyses of the sands are reported. The developments of the silica industry in Eastern Canada since the last report (cf. C. A. 18, 369) are reviewed. L. W. RIGGS

The salt deposits in the upper valley of the Aller River at Wefensleben-Belsdorf. WALTER ZWANZIG. *Kali* 22, 45-9, 62-6, 76-9, 92-4, and 113-6(1928).—Descriptive. A. L. HENNE

Helium and the genesis of petroleum. C. COLERIDGE FARR AND M. N. ROGERS. *Nature* 121, 938(1928).—Using Lind and Bardwells' conclusions that hydrocarbons undergo chem. change when bombarded by α particles, and their quant. results, and assuming that He arises from α particles ejected by radioactive substances, F. and R. conclude that about 2 tons of liquid hydrocarbons should theoretically be produced per cu. ft. of He. The dense compds. in petroleum are possible remnants of the original hydrocarbon material from which such formation took place. Other evidence is also suggested. ALDEN H. EMERY

The repartition of the eruptive rocks. BARON FRANZ NOPCSA. *Földtani Közlemény* 56, 149-60(1927).—Petrographical. A. L. HENNE

Some rocks found in drilling (for petroleum) at Ripi, Lazio. G. CUMIN. *Atti accad. Lincei* [6] 6, 518-21(1927).—Andesine, labradorite and augite are the chief components, with biotite, olivine, magnetite, and apatite in small quantities. The mineralogic characteristics are described in detail. C. C. DAVIS

Hypersthene-andesite of Blair Duguid, near Allandale, N. S. Wales. W. R. BROWNE AND H. P. WHITE. *J. Proc. Roy. Soc. New South Wales* 60, 372-87(1926).—The hypersthene-andesite of the Blair Duguid hills appears some distance away in an altered form as the pebbles of a conglomerate. This change has apparently been effected by solns of magmatic origin, and has involved the addn. of both Na and K to the rock, and the transformation of the hypersthene into iddingsite in some places and into carbonates in others. B. C. A.

Andesite rocks in the vicinity of Helemba, Kom. Hont, Hungary. FRANZ PAPP. *Földtani Közlemény* 56, 195-200(1927).—A mineralogical description is given. A. L. HENNE

The petrogenesis of the Siebenbürg Eozoic. I. Petrography. ELEMER V. SZADECZKY KARDOS. *Földtani Közlemény* 56, 221-42(1927). A. L. HENNE

Differentiation products resembling gabbro in the vicinity of Szarvaskő, (Hungary). S. VON SZENTPÉTERY AND K. EMSZT. *Földtani Közlemény* 56, 200-16(1927). A. L. H.

Grünerite rocks of the Lake Superior Region and their origin. STEPHEN RICHARZ. *J. Geology* 35, 690-708(1927). In the Marquette iron district of Mich., grünerite was formed from siderite-bearing cherts through metamorphism induced by dioritic intrusions. Associated with the grünerite are magnetite, garnet and quartz (or calcite). In the Mesabi range district of Minn., the original rock was chert and greenalite. In the eastern portion of this range, at the gabbro contact, grünerite, fayalite and magnetite were developed. W. F. HUNT

The relative effectiveness of bacteria as agents of chemical denudation. GEORGE THIEL. *J. Geology* 35, 647-52(1927).—Seven types of crushed rocks—granite, syenite, monzonite, diorite, basalt, shale and ferruginous chert—were subjected to leaching under normal conditions and under sterile conditions. The salinities of the solns. under the 2 conditions were compared. The total of the analyzed constituents is 53% greater for solns. with bacteria than without, the increase in Ca and Na being especially noteworthy. W. F. HUNT

Stalactites. J. A. LEBEL. *Compt. rend.* 186, 1306(1928).—In a grotto at Eyzies in Dordogne stalactites and other CaCO_3 deposits were covered with a sort of calcareous growth which spread in all directions but in general upwards. The origin of this coating appeared to be due to a divided fall of incrusting water. The stalactites give sparks under the pick which are not due to included SiO_2 or firestone, but may be a kind of phosphorescence. L. W. RIGGS

Laboratory tests on physical properties of water-bearing materials. N. D. STEARNS. U. S. Geol. Survey, *Water-Supply Paper* 596F, 121-76(1927).—Methods of sampling water-bearing strata and of detg. their apparent sp. gr., mech. compn., porosity, moisture equiv., and permeability to water are described in detail, with reference to certain Am. water-bearing gravels; tables showing the phys. properties of these are included. B. C. A.

Helium content of uraninite from Karelia. V. KHILOPIN. *Compt. rend., acad. sci. U. R. S. S. [Russia]* 1926, 195-7.—Six samples contained 4-5 cc. per g., and two 0.3-0.4 cc. The He content is thus not proportional to the Pb:U ratio. B. C. A.

The radium content of some Nova Scotian minerals. CARL KENTY. Dalhousie Univ., Halifax, N. S. *Proc. Trans. Nova Scotian Inst. Sci.* 16, 174-5(1928).—The Ra content per g. of mineral has been measured for a few Nova Scotian specimens: NaCl or KCl salt, from Malagash, less than 5.10^{-10} ; light feldspar from Governor's Lake, $8.7.10^{-12}$; dark feldspar from the same, $14.0.10^{-12}$; siliceous slate from Upper Musquodoboit, $2.6.10^{-12}$. 9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, R. H. ABORN

Charcoal for use in metallurgy. N. N. ROGATKIN AND V. A. BORETSKAYA. *J. Chem. Ind. (Moscow)* 4, 150-2(1927). Charcoal used in metallurgy must possess a high C content and must be able to withstand high pressures. The higher the temp. at which wood is carbonized the greater the C content of the charcoal and its ability to withstand pressure. Wood distn. plants usually do not yield good metallurgical charcoal on account of insufficiently elevated temps. at which the distns. are carried out. The authors' expts. had chiefly the purpose of clearing up the influence of the speed of the operation of wood carbonization on the quality of the charcoal obtained. They used Vik's needle to establish the weight which crushes a given sample of charcoal. The expts. have shown that rapid carbonization of wood, particularly of resinous variety, is not favorable to mech. strength of charcoal. The reason is that wood resins, on being rapidly decompd., inflate and swell the charcoal and thus decrease its mech. resistance. To obtain good charcoal it is advisable to carbonize wood slowly, thus giving the resins an opportunity of distg. off, and to attain a final temp. of at least 800°. Pine and birch wood were carbonized for a comparison and it was found that birch charcoal was twice as resistant to crushing efforts as pine charcoal. BERNARD NELSON

Flotation of fluorspar ores for acid spar. WILL H. COGHILL AND O. W. GREEMAN. *Bur. Mines Repts. of Investigations No. 2877*, 3 pp., *Pit and Quarry* 16, 79-80(1928).—Gravel spar (85% fluorspar, 5% SiO₂) glutts the market while acid spar (98% fluorspar, 1% SiO₂) is scarce. Lab.-scale flotation tests show that calcite is more floatable than silica and that flotation increases the yield of acid spar when the grinding causes almost perfect liberation of the silica. The flotation reagents consist of oleic acid, Na oleate, Na silicate, Na₂CO₃, heavy crude pine oil and steam-distd. pine oil. Some ores yield acid spar more readily if flotation is preceded by gravity concn. Conversion of some of the gravel spar to acid spar will give a healthier tone to the market. W. H. B.

The development of the dressing of roasted spars at the Storch & Schöneberg mines in Gosenback. RUDOLF LAMBERT. *Arch. Eisenhüttenwesen* 1, 11-17(1927).—The development of the dressing plant at this mine has kept in pace with advances in technic, the degree of concg. approaching the ideal. The methods and machines used are described, and comparisons made. J. BALOZIAN

The importance of air control in efficient cupola practice. P. H. WILSON. *Proc. Inst. Brit. Foundrymen* 20, 57-105(1926-7).—Control of the air blast in cupola operation by means of a recording vol. pressure gage results in (1) economy of fuel, (2) reduction in scrap castings and (3) saving in Fe losses. Exptl. test data are shown in tables and graphs of the temp., pressure and analyses of the gases at different points in the cupola. DOWNS SCHAAF

Non-ferrous foundry practice. A. LOGAN. *Proc. Inst. Brit. Foundrymen* 20, 378-94(1926-7).—Scientific metallurgical consideration is given to the melting and pouring operations of brass founding. DOWNS SCHAAF

Investigations on the reduction of oxide ores. B. BOGITCH. *Rev. métal.* 25, 247-61(1928); cf. *C. A.* 21, 1950.—An investigation into the mechanism of reduction of oxide ores, exclusive of highly refractory oxides (such as Cr, W, etc.) and those of more or less volatile metals (such as Pb, Zn, etc.), with a view to elucidating the causes of the numerous difficulties encountered in similar operations. The ores selected con-

sisted of a Ni ore (6.90% Ni) with a MgO gang (MgO 17.21, SiO₂ 48.60%) contg. relatively little Fe (11.70%), a Co ore (5.01% Co) with Al₂O₃ and Fe gang (Al₂O₃ 17.72, Fe 26.20, SiO₂ 28.80%), and a highly ferrous (Fe 57.40, SiO₂ 14.16%) Ni ore (Ni 5.30%), as they had been found to be exceptionally delicate to treat. After grinding and agglomerating with glue, the ore was calcined in contact with a solid reducer: with wood charcoal reduction is very slow below 700°; at 800° and above it is rapid, but slows down considerably towards the end of the reaction; with coke reduction is very slow below 900°, but above this temp. it is an almost linear function of the time of calcination, so that at the same temp. (950°) the same time is required for complete reduction by coke and by wood charcoal. The difference in behavior of the 2 reducers is due to the greater ease with which charcoal is gasified, presumably on account of the air and H₂O which it contains, as its reducing action is decreased if it has been previously calcined. Reduction takes place as well when the reducer is placed under the ore as when it is mixed with the ore, but if it is placed above, only the upper layers of ore are reduced, probably because CO₂ accumulates in the bottom of the furnace and prevents CO from reacting with the ore. With a mixt. of powd. coal and ore, reduction is very rapid at first, but soon slows down, and the time required for complete reduction is the same as with briquets. For very rapid reduction a gaseous or liquid reducer must be used (such as oil, petroleum or tar). Addn. of CaO or of silicates which are not fusible at the calcination temp. does not affect the rate of the reaction; but a few 0.1% of a Na salt appreciably slows down the end of the reduction. With cylinders or briquets cut out of the ore, the phenomena take place in the same way as with agglomerated cylinders or briquets, but the rate of reduction may vary with the compactness of the material. After reduction of agglomerated ore by calcination there is considerable shrinkage in size, partly because of decrease in size of the particles through loss of O and partly because of closer welding of the reduced particles, and this shrinkage is accompanied by considerable increase in the hardness and strength of the agglomerate. But if calcination is conducted in such a manner that reduction and contraction in size occur simultaneously (e. g., if coke is used), the agglomerate crumbles as it is reduced; and this is enhanced in presence of unreducible substances, particularly if they retard reduction (e. g., Na salts). Absorption of C by agglomerated ore depends on the reducing temp.: a Ni agglomerate heated 48 hrs. at 800–1000° can absorb up to 0.80% C and has a grayish white fracture; above 1000° absorption of C produces black spots inside the agglomerate which begin to appear as soon as the C content exceeds about 0.30%. When CO or fresh wood charcoal is used, absorption of C begins only after reduction is complete, while with coke the agglomerate can contain at the same time C in the superficial layers, pure metal further in, and unreduced ore at the center. Desulfurization begins only after reduction is complete and carburization has set in; though small, it is of importance in the production of certain pure metals, such as Ni or Co, which are used in the form of agglomerates. Addn. of 5–10% limestone to a slow reducer (coke) increases the rate of reduction; whatever the nature of the reducer, it accelerates carburization and desulfurization; these actions take place only during the decompn. of the CaCO₃ by heat, and CaCO₃ cannot therefore be replaced by CaO. B.'s expts. on the smelting of ores (described in some detail) lead to the following conclusions: (1) The degree of reduction depends only on the amt. of reducer used, provided the smelting temp. is sufficiently high to enable the metal to sep. from the slag, and provided also heating is sufficiently slow. (2) In the rapid fusion of Cu, Ni and Co oxide ores, it is only exceptionally that equil. between the ore and the reducer can be obtained; the absence of equil. can be observed either by analysis of the slag, which is too rich, or by the manner in which fusion takes place, it giving rise to sepn. of the reducer and swelling of the slag. (3) Addn. of various fluxes permits of increasing the rate of reduction and approaching nearer to the state of equil. (4) The action of fluxes varies with their nature and with the compn. of the ore, and the proportion to be used can only be detd. experimentally. B. has devised a method for the purpose, consisting essentially in first making a series of slow fusions at a suitable temp. (say 1550°) with varying amts. of reducer to det. the amt. required to obtain the desired degree of reduction (if the temp. is found to be too low, add 1 part CaO to 1 part ore), and then making a second series of quick fusions to det. the proportion of flux which must be added to give the most fusible and fluid slag. These results give the optimum compn. of the smelting charge, but not necessarily the most economical treatment. Starting from the results of these lab. tests com. operations are adjusted to obtain the most economical results.

A. PAPINEAU-COUTURE

Recovery of copper and zinc from brass scrap. I. A. KAZARNOVSKII and V. M. ZVENIGORODSKAYA. *Papers Karpov Chem. Inst. Bach. Memorial Vol.* 1927, 101–9;

cf. Vinogradov and Vinogradova, *C. A.* 22, 2814.—Brass is calcined in a current of air, the oxides formed are dissolved in H_2SO_4 , and the soln. obtained is boiled with brass turnings (non-calcined). The Zn of the latter, on dissolving, ppts. an equiv. amount of Cu. Whereas in neutral soln. the pptn. of Cu by brass is very slow, free H_2SO_4 in concn. of 2-3% acts as an excellent catalyzer and the pptn. of Cu can thus be made practically complete. Cu of 90% purity is thus obtained and can easily be transformed into $CuSO_4$. The $ZnSO_4$ which remained in soln. can be utilized in the manuf. of pigments, lithopone and $ZnCl_2$.

BERNARD NELSON

Xanthate and pine oil float native copper in amygdaloid ores. A. W. FAHRENWALD. *Eng. Mining J.* 126, 58-9(1928).—Cooperative research work by the Michigan Coll. of Mines and Technology and the U. S. Bur. Mines shows that fine grinding is unnecessary to unlock Cu in amygdaloid ores. With the proper reagent combination Cu as coarse as 28-35 mesh floated well and minus 65 mesh Cu floated readily. Flotation is easier when the Cu is mixed with a pulp of finely ground barren rock. Xanthate in a slightly alk. pulp in conjunction with a variety of oils is the best reagent tried. The lab. tests indicate that the use of flotation instead of the all-gravity process results in addnl. Cu recovery, lower smelting cost of concentrate, lower slag loss, and no table middling to regrind. Large-scale expts. are to be conducted in various plants in Michigan.

W. H. BOYNTON

The Harris process of lead refining. R. WINTER. *Eng. Mining J.* 125, 725-8 (1928).—The method and equipment are outlined for removing As, Sn and Sb from Pb bullion and alloys by passage through molten NaOH, NaCl and $NaNO_3$. The process represents the adoption in a cyclic process of exact principles of chem. engineering combined with the use of automatic self-contained machine for the metal treatment. The process may be applied in the treatment of secondary or residual scrap leads with recovery of the impurities sep. from one another in marketable form. In a dry treatment the molten impure metal is circulated through a molten mixt. of NaOH and NaCl. Impurities are oxidized and enter the reagent through the action of atm. O_2 , accelerated in the case of As, Sn and Sb by the gradual addn. of $NaNO_3$. The second treatment consists of sepgg. Na arsenate, stannate and antimonate, and ZnO in marketable form. The means of calcg. the amounts of NaOH, NaCl, and $NaNO_3$ needed are shown and the app. employed for circulating the molten Pb through the Na salts illus. W. H. R.

The precipitation of gold and silver from their dilute solutions. MATAICHI YASUDA. *Bull. Chem. Soc. Japan* 3, 113-8(1928).—A metallic alloy of Mn and Pb is suitable to ext. Au and Ag from their dil. solns. in sea water. The more efficient compn. seems to be 4% Mn. The technical details are: put the Pb and the Mn powder together in a steel case; hammer it strongly with an air hammer so that a plate 0.07 mm. thick is obtained; hang the plate in a beaker contg. 3 l. sea water, stir for a few hrs.; replace the sea water 6 times; roll the plate to a small vol.; put in a crucible; add 2-3 g. PbO and fuse to oxidize the remaining Mn; cupell the button; weigh the Au and Ag as usual. The metals should be tested for noble metals before use. The efficiency of the Au extn. is about 40-50% in 100 hrs.

A. L. HENNE

The relations between the slagging of iron and manganese in the Thomas process. E. FAUSR. *Archiv Eisenhüttenwesen* 1, 119-26(1927).—The equation $[Mn]_s/[Fe]_s = K \cdot [Mn]_l/[Fe]_l$, in which $[Mn]_s$, $[Fe]_s$, $[Mn]_l$ and $[Fe]_l$ are the resp. quantities of Mn and Fe in the slag and in the ingot steel, has been derived from phys.-chem. considerations. Its validity, for the Thomas process, is tested by blasting a large no. of charges under varying conditions, toward the end of a blast 80% ferro-Mn or a rich Mn ore is added, and the equil. between Mn and Fe in the steel and in the slag detd. Samples of pig Fe, ingot steel and slag from each run are analyzed and the temps. detd. at the moment of sampling. From these data curves are obtained showing the relation between the slagging of Fe and Mn, and, the Mn content of the pig Fe and of the ingot steel, the latter curve giving $K = 247$. Values are obtained from an altered form of the above equation which when plotted give the relation between the slagging of Mn and Fe in % of the combined amts. of both substances in the process. In any smelting process there is for the ratio Mn:Fe in the slag phase a definite ratio of Mn:Fe in the metal phase. The value of K depends upon the process, having an av. value of $K = 1350$ in the acid Bessemer process.

J. BALOZIAN

Platinum and the platinum metals. G. H. STANLEY. *J. S. African Chem. Inst.* 10, 3-48(1927).—An illustrated review and survey of the history, source, methods of refining, properties and uses of these metals is presented.

ALBERT THOMAS FELLOWS

Heat investigations on a Siemens-Martin furnace. G. NEUMANN. *Archiv. Eisenhüttenwesen* 1, 111-7(1927).—Investigations of the combustion relations in the heating chamber of a 40-ton tilting furnace, fired with producer gas from brown coal

briquets. The gases are analyzed here, it being found necessary to use a protective uncooled tube over the one cooled with a water jacket. The combustion is found to be incomplete (O_2 and unburnt gas being present) and extends over the entire hearth, being greatest over the bath and at the back wall. The O_2 content of the hearth decreases from the front backwards (specially at the flame end of the furnace) and the top down. The CO_2 concn. increases at the flame and from the front to the rear, but decreases in this direction at the outlet end. At the fire end it increases from the top downwards, no visible change in this direction being detectable at the middle door or the escaping end. Although the fresh gas contains CH_4 , none appears in the hearth it being burnt or decompd. The effect of increasing the air velocity and decreasing the gas velocity on the completeness of combustion, increasing the furnace efficiency and decreasing the fuel consumed is discussed. The decompn. of the gas in the chambers is studied, and is found to be retarded by cooling the chambers and flues. The temp. relations in the lattice work of the chambers and its effect on the gas current are investigated.

J. BALOZIAN

Contribution to the calculation of the useful heat in Siemens-Martin fusions. CARL SCHWARZ. *Arch. Eisenhüttenwesen* 1, 33-40(1927).—A more rigorous interpretation to the idea of "useful heat," being given with the aid of a cyclical process, some of the constns. to be found in the literature of metallurgy are tabulated and considered critically.

J. BALOZIAN

Modern scientific basis of the operation of high-production blast furnaces. MAURICE DERCLAYE. *Rev. métal.* 25, 1-13, 120-47, 195-211(1928).—A discussion, largely mathematical, of the theory of the operation of the blast furnace, showing that the 2 main economic factors, namely, max. production and min. fuel consumption, are not irreconcilable, and examg. the effects on production and on fuel economy of factors dependent on the fuel, on the blast, on the design of the furnace and on the phys. state of the constituents of the charge. It is also shown that American blast furnaces are operated as efficiently as European ones from the standpoint of Gruner's ideal.

A. PAPINEAU-COUTURE

The new heat diagram for iron blast furnaces. P. REICHARDT. *Arch. Eisenhüttenwesen* 1, 77-101(1927).—In this diagram the heat required in the various temp. zones of a blast furnace is compared with the heat available. Thus, the curves for a Rhine-Westfal Thomas furnace are plotted and discussed in detail, showing: (1) the heat consumed and that required in the various temp. zones against their temps. (for 100 kg. crude Fe ore); (2) the heat content of the gases (66.4 kg C_k) and that available against the temps. of the gases; (3) the heat required and that recovered against the temps. of the gases and the charge; (4) the min. amt. of coal required against the temps. of the charge. The heat diagrams of another Thomas, an American, a Minette Fe-steel blast furnace, and charcoal furnace are plotted, published figures being used. From these it is apparent that only in the highest part of the furnace do the throat gases have the large surplus of heat shown, the heat being practically completely used up to a temp. of 900° . Applying the heat diagram, a study is made of the influence of (1) $CaCO_3$ on the fuel consumption, (2) crude spathic Fe ore, (3) the quantity of slag, (4) the temp. of the blast, (5) its degree of dryness, (6) the sepn. of coal dust from the gas, and (7) the fuel consumed in the remelting of scrap in the blast furnace, (8) the prospect of using O_2 in the blast furnace, (9) the use of air enriched with O_2 instead of the heated blast, and (10) the possibility of regulating the furnace heat. It is shown that no benefit can be derived from (9), while the simultaneous injection of powd. coal and O_2 promises good results.

J. BALOZIAN

The injection of charges and fuels into the hearth zone of iron blast furnaces. E. BERTRAM. *Arch. Eisenhüttenwesen* 1, 19-32(1927).—No difficulty is encountered in injecting charges into blast furnaces working at low pressures. This is not suitable for the blasting of refined cast Fe, but may be used for the production of half-refined Fe or of castings from the first melt. Here the process is economical, only, when it is used in conjunction with cold air. Whether it may be used in steel works with profit is problematical; it acts unfavorably in the Mn reduction. The injection of fuels is not practical, expt. and theory showing this, at least when the fuel is injected through the main tuyères.

J. BALOZIAN

Annealing furnace for rolling mill heated with blast-furnace gas. J. MEISER. *Stahl u. Eisen*, 48, 822-3(1928); *Arch. Eisenhüttenwesen* 1, 639-46(1927-8). J. A. S.

Some parallels and comparisons in blast-furnace and cupola practice. J. E. FLETCHER. *Fuel Econ. Rev.* 7, 55-64(1928).—Instead of estg. the heat balance of a cupola or blast furnace simply in terms of amt. of C used in the production of a ton of Fe (neglecting the rate of smelting or melting, vol. of gases, the fuel, ore or metal and

the flux involved), it is shown that what may be good operating conditions for one type of furnace may not serve for the other. Special stress is laid upon the analysis of throat gases, as these may be interpreted to show the type of reaction (reduction of Fe_2O_3 by C or CO) taking place and the efficiency of the plant. The modifying effects of various factors entering into consideration are discussed fully. W. C. EBAUGH

Transformation of Cowpers with a view to improving their efficiency. A. COUSIN. *Rev. métal.* 25, 231-4(1928).—Diagrams are given and discussed showing the relation between gas consumption, temp. of the blast and calorific efficiency. A. P.-C.

Protection of steel against oxidation at the end of the open-hearth process and decrease in the amount of gas occluded. V. N. TSVIBEL. *Tekhnika i Proizvodstvo* 36-49 (1927); *Rev. métal.* 25 (Extraits), 135-7 (1928).—After discussing the advantages of elec. steel over open-hearth steel as generally made at the present time from the standpoint of the absence in the former of occluded gases, and after discussing also the mechanism of the re-oxidation of the metal at the end of the open-hearth process, T. proposes protecting the slag from the action of the oxidizing atm. by covering the bath towards the end of the process by a layer of solid or liquid heavy hydrocarbons. A no. of exptl. runs have been made, but the process has not yet been applied commercially. The advantages of the process are outlined. A. PAPINEAU-COUTURE

Modern galvanizing practice. HEINZ BABLIK. *Zentr. d. Hütten- u. Walzsch.* 30, 549-53 (1926); *Chem. Zentr.* 1927, I, 945-6—Descriptive C. C. DAVIS

Sponge iron as a melting base. N. K. G. THOLAND. *Iron and Steel of Canada* 11, 210-11 (1928).—Sponge iron as made by the Sicurin process for use as a melting base in the manuf. of open-hearth and elec. steel, contains 97% Fe, less than 4% FeO , 0.010-0.013% P, up to 0.025% S, 0.15% V, probably as V_2O_5 , 0.03% C, the remainder being a gang consisting, for the most part, of SiO_2 . Tests made by substituting sponge iron, for a certain portion of the charge in making steel for wire rope manuf., showed an improvement of from 6 to 20% in torsional properties, and from 20 to 35% in bending properties. Sponge-iron steels show less tendency to crack than other steels of good quality and are also practically free from red-shortness. DOWNS SCHAAP

Some experiences with malleable cast iron. H. FIELD. *Proc. Inst. Brit. Foundrymen* 20, 564-96 (1926-7).—Many practical data are given in connection with the manuf. and testing of malleable castings. DOWNS SCHAAP

Semi-steel. J. E. HURST. *Proc. Inst. Brit. Foundrymen* 20, 482-96 (1926-7).—The behavior of C in the remelting of mixts. of steel and cast iron in the cupola, the character of the steel adds, and the soundness, regularity and compn. of the final castings, are discussed. DOWNS SCHAAP

Technology of casting metals. HUGO MÜLLER. *Z. Ver. deut. Ing.* 72, 879-84 (1928).—A well-illustrated lecture covering the theory and practice used in modern foundries. W. C. EBAUGH

The manufacture of a large steel casting. P. A. MELMOTH AND T. W. BROWN. *Proc. Inst. Brit. Foundrymen* 20, 232-66 (1926-7).—The complete history is outlined of the production of a large cast steel propeller shaft bracket and the following operations are described at considerable length: the manuf. of the steel, the prepn. of the sand, the making of the cores and mold, the annealing, welding, inspection and testing of the castings. DOWNS SCHAAP

Carburizing with mixtures of hydrogen and natural gas. W. P. SYKES. *Fuels and Furnaces* 6, 913-8 (1928).—The most active carburizing constituent of natural or illuminating gas is CH_4 , comprising about 75% of the former and 25% of the latter. It decomposes at high temp., and at 1000° a gas contg. only 1.02% CH_4 is satd. with it. A W-wound furnace was used to heat Armco Fe samples up to 1100° in an atm. of CH_4 and H_2 of fixed compn., and the results were observed with the microscope. The rate and depth of C penetration in the Fe depended on the temp. An increase of CH_4 concn. at first increased the depth of penetration up to a certain point, then merely raised the C content of the outer layer. It is shown how the gas compn. may be adjusted for heating a steel of given C content so that the decarburizing effect of H_2 is just balanced against the carburizing effect of CH_4 at the desired temp. and the atm. will thus be neutral. For instance at 900° a 0.3% C steel was decarburized in H_2 plus 0.5% natural gas, and carburized in H_2 plus 0.9% natural gas. If the gas contained water vapor, much more CH_4 was required for carburizing. G. F. C.

Trend of engineering developments in steel. B. D. SAKLATWALLA. *J. Soc. Chem. Ind.* 47, 198-202T, 210-2T (1928). E. H.

The fracture tests of steel workers. F. JANSEN. *Arch. Eisenhüttenwesen* 1, 147-55 (1927).—Fracture tests are widely used in steel mills, because of their simplicity and rapidity, for detg. the course of fusion. A description of those for the detn. of P

and C is given. It is shown that the red-shortness, and the impaired malleability assocd. with it, is not dependent on the abs. amt. of the O_2 and Mn, but appears when the O_2 is in excess of the quantity necessary to unite with Mn to form MnO . The larger the excess of O_2 , the greater the red-shortness and the coarser the grain structure. Temp. influences the red-shortness between 700° and 1025° , its effect being greatest at the latter temp.

Stainless steel. ALBERT F. WHITE AND CLAUDE L. CLARK. Univ. of Michigan. *Eng. Research Bull.* No. 4, 9-82(1926).—A review.

E. H.

Behavior of steel under prolonged stress at high temperatures. A. POMP. *Chem. Fabr.* 1928, 53-4.—Recent work on the "creeping" of steel at high temps. is reviewed and the necessity of detg. the "permanent strength" of steels which are to be used for high-pressure work at elevated temps. is emphasized. The "permanent strength" of a steel is defined as the highest load which the steel will support at any given temp. without increasing in length after 3-6 hrs. by more than 0.001% per hr. For plain C steels this value remains fairly constant up to 300° , then falls very rapidly with rise in temp.; the permanent strength and the rate at which it decreases with rise of temp. increase with the C content of the steel up to the eutectoidal point, provided that the pearlite constituent is in the lamellar form. Steels in which the pearlite is in a granular form have a much lower permanent strength.

B. C. A.

Cyanide hardening of steel. SAM TOUR. *Fuels and Furnaces* 6, 883-92(1928).—Cyaniding introduces both C and N into steel. $K_4Fe(CN)_6$ was first used for cyaniding tools but NaCN is the chief reagent now used. The fumes arising from molten NaCN are oxidized at once in air and thus rendered harmless. The process of Merten using CN gas is described, also the Shimer cyanide process. As the temp. of case-hardening is increased, less N and more C are absorbed by the steel. The depth of penetration increased with both time and temp. A cyanide bath should not generally be used above 800° , and it is unnecessary to have over 25% NaCN in the bath, or to heat steel over 20 min. in it. Carbonate is formed by oxidation at the surface, and may decarburize a high-C steel though the same bath may contain enough NaCN to carburize a low-C steel. The best concn. and temp. of the cyaniding bath depend on the type of steel to be treated. When the temp. was kept well below the crit. point of the steel, and the time of treatment was not over 20 min., cyanide brittleness of the core was avoided. Although in practice baths contg. as much as 75% NaCN are used, it is more economical to keep the NaCN content at 30%. Cyaniding is used for cases not over 0.015 in. thick; the time of treatment is not over 40 min., and depends on the size of the piece treated. The temp. varies from 730° to 900° ; for a very thin skin on small pieces, 2 or 3 min. treatment at 900° is satisfactory. The cyanide pieces are usually quenched in water, and some kinds of oil cause trouble in cleaning.

G. F. C.

The effect of the form of the ingot mold and deoxidation on the crystallization of (steel) ingots. FRIEDRICH BADENHEUER. *Stahl u. Eisen* 48, 713-8, 762-6(1928).—Ingot molds of various conical forms were used to det. the influence of the form on the crystn. of basic open hearth steel melts. In general it was found, that the heavier the conical-shaped ingots used, the sounder the ingots obtained. The ingots so obtained were noticeably free from secondary piping. With increasing wall thickness the extent of the transcrystn. zone is increased. The deoxidation was investigated on 3 melts to which various amts. of Fe_3Si and Al were added. A cone-shaped central part consisting of globular crystallites was observed in every block. With small quantities of deoxidizing agents this cone extends through the whole length of the ingot; with larger amts. the cone ends below the head of the ingot. Through properly adjusted cooling rate this globular structure can be transformed into dendritic structure, the structure prevailing through the rest of the block. The relationship between the primary structure and segregation is shown and an explanation given of the phenomena observed during solidification.

J. A. SZILARD

Combined iron and steel. J. FERDINAND KAYSER. *Metallurgist* (Suppl. to *Engineer* 145, No. 21) 73-5(1928).—The method of manuf. is given and the microstructure is illustrated. The steel face may have a Brinell hardness of 600. D. B. DILL

The hardening of carbon steel during deformation as a function of temperature, time and structure. F. SAUERWALD, L. MICHALSKY, R. KRAICZEK AND G. NEUENDORF. *Stahl. u. Eisen* 48, 770-71(1928); *Arch. Eisenhüttenwesen* 1, 717-20(1927-8).—Cold and warm deformations are characterized by hardening and recrystn., resp. Cold deformation causes a hardening and the formation of a corresponding fiber structure; no hardening occurs during hot deformation, only a recrystn. The temp. line so detd. between cold and warm deformation depends for a given material on the velocity of deformation, which also governs both the hardening and the recrystn. This temp. line was

detd. for a perlitic steel and one with 1.71% C. Test pieces 10 mm. high were compressed by means of a drop hammer at various temps., and their Brinell hardnesses detd. before and after compression at test temp. There is a max. of the capacity of hardening in the range of blue brittleness. The whole temp. range below the perlite line is the sphere of cold deformation for steel. It was found that at 820° a steel with from 0.8 to 0.9% C shows no hardening shortly after a quick deformation so that this temp. range must be termed as the sphere of hot deformation. For pure Fe-C alloys the range of γ solid soln. and that of hot deformation are identical if the velocity of deformation is high. J. A. SZILARD

Surface decarburization of carbon steels. E. H. SCHULZ AND W. HÜLSBRUCH. *Arch. Eisenhüttenwesen* 1, 225-40(1927); *Stahl u. Eisen* 47, 1694-5(1927).—The decarburizing action of various atms. on the 3 steels contg. 0.5, 0.9 and 1.3% C has been detd. at 750-1050°. In all gases, except pure N and carburizing gases, such as coal gas, CH₄, or CO, severe decarburization takes place at 900° or above. Pure N and CH₄-H mixts. are inert, but even traces of CO₂ or steam in these gases causes severe decarburization to occur. A similar action ensues if very small quantities of steam or CO₂ are present in gases which, if pure, act as carburizing agents. In H or in a technical "reducing atm." decarburization commences at 550-600° and in steam, CO₂ or air at 800°; in pure O or perfectly dry air no action takes place below 850°. The depth of decarburization in a given time increases in all cases with rise of temp. and, above 850°, with increase in the C content. The ferrite crystallites formed on the surface by decarburization above 750° are extraordinarily coarse and columnar in shape, the long edges being perpendicular to the surface of the metal. In cases where a coating of scale is formed, this acts as a protective layer below 850°; the heaviest layer of scale is formed in a salt bath and only slightly thinner layers in O or steam. B. C. A.

Silicon-carbon sum is factor in high-duty cast iron production. ANDRE LEVI. *Foundry* 56, 478-80(1928).—Semi-steel made in the cupola with 20 to 30% steel scrap varies in strength inversely to the sum of the C and Si contents. When this sum is not over 4.6, the strength is over 28,000 lbs. per sq. in., and no strength above 35,000 lbs. per sq. in. can be obtained if this sum is over 4.6. The combined C and the Mn should each be 0.8%. With total C from 3 to 3.2%, which gives a fluid metal and is practical in cupola practice, Si should vary from 1 to 1.6%, to give a gray Fe of max. strength. The addn. of steel to the charge produces no bad effects, but it is better to attain the desired compn. with pig Fe alone if possible. The P may be as high as 0.3% to increase fluidity, without decrease in strength. The use of Cr involves heat-treatment and is costly. Certain kinds of pig Fe always give better results when remelted because the graphite in them dissolves completely at cupola temp., while in ordinary pig Fe some graphite does not dissolve and causes a coarse structure after remelting. GEO. F. COMSTOCK

Ways to improve gray-iron castings. RICHARD MOLDENKE. *Iron Age* 121, 1747-9 (1928).—The increased strength of cast Fe melted under conditions of super-heat, over that made in the ordinary practice of cupola operation, is explained on the basis of the phys. condition of the graphite pptd. during the change in the Fe from the molten to the solid state. The microscopically small graphite nuclei, which serve as the starting points of coarse crystal growth, are completely dissolved in Fe when the molten metal is heated to extremely high cupola temps., and thus the growth of large graphite crystals is inhibited. DOWNS SCHAAP

Strength and structure of iron and non-ferrous metals. CONSTANTIN REDICH. *Apparaturbau* 40, 133-8(1928).—The properties of cast Fe, Ni-steel, rustless steel, Cu and a few of its alloys are discussed with special reference to their use in contact with steam at high temps. Thirteen cuts, 6 graphs and 10 photomicrographs. J. H. M.

Hydrogen in electrolytic zinc. W. ROY ELLIOT. Dalhousie Univ., Halifax, N. S. *Proc. Trans. Nova Scotian Inst. Sci.* 16, 152-4(1928).—E. verifies the conclusions of Ralston (C. A. 19, 2303): electrolytic Zn contains 0.3-2 cc. of H per g. of metal, depending on the c. d. and ZnSO₄ concn. To measure the amt. of gas a strip of metal was placed in an evacuated Pyrex tube and melted by a resistance furnace; the gas evolved was pumped off and measured. A. L. HENNE

Studies on the resistivity of chromium-plated metals to the action of chemical reagents. TORU MURAKAMI. *J. Soc. Chem. Ind. Japan* 31, 132-6(1928).—Metallic Cr is generally in two states, passive and active. Commercial Cr is ordinarily passive and is highly resistant to acids and alkalis, excepting HCl. But the new surface obtained by breaking commercial Cr is not resistant to acids. Moreover, passive Cr which is in contact with Zn, Fe or some other metals in acids becomes active and is no longer resistant to acids. Electroplated Cr generally has pin holes and thus the base metal

beneath is exposed through them. The fresh Cr film is not resistant to acids, but after a time it becomes passive. The Cr film prep'd. by Y. Kato and M. (C. A. 22, 2329) is resistant to many reagents and gases. Tables showing the exptl. results for the action of many acids, alkalis, salts and the atmosphere on Cr-plated metals are given. Length of time after plating, and pin holes in the Cr film are the two important factors in testing the resistivity of Cr-plated metals.

Effects of temperature on the properties of alloys. J. COURNOT. *Rev. sci.* 65, 589-90(1927).—A brief review of our knowledge of the variations of the properties of alloys with temp. and of their practical consequences. A. PAPINEAU-COUTURE

Alloys resistant to hydrochloric acid. B. WAESER. *Chem. Fabr.* 1928, 17-8.—A review of recent work, together with a table showing the compn. and resistance to attack by HCl soln. of various strengths of 39 Am. acid-resisting alloys, 3 German special steels, and 2 ferrosilicon alloys.

B. C. A.

Aluminum alloys. H. HYMAN. *Proc. Inst. Brit. Foundrymen* 20, 350-65(1926-7).—Methods of heat treatment and details of foundry practice are given for a few com. alloys of Al.

DOWNES SCHAAF

Heat-treatment of aluminum and its light alloys. ROBERT J. ANDERSON. *Fuels and Furnaces* 6, 901-2(1928); cf. C. A. 22, 1941.—Equipment used for the heat-treatment of light alloys and various installations are briefly described. For annealing, ordinary fuel-fired or elec. furnaces are largely used; for heating previous to quenching fused salt-baths are used; and for aging, hot oil, boiling water, or circulated hot air is used.

GEO. F. COMSTOCK

The structure of tin-antimony alloys. W. BRONIEWSKI AND L. SLIWOWSKI. *Compt. rend.* 186, 1615-6(1928).—A brief account is given of the compds. found in the Sn-Sb system by earlier investigators. Hardness, thermal, microscopic, elec. and other phys. tests carried out on samples annealed 1200 hrs. at 200° indicated that only a single compd., Sn_3Sb_2 , occurred. An equil. diagram is shown and explained. Alloys contg. up to 50 at. % Sn deposit first on freezing a solid soln. of Sn in Sb, and 10 at. % Sn remains in solid soln. at room temp. At 425° a peritectic reaction occurs, the compd. Sn_3Sb_2 retaining considerable Sb in solid soln. Alloys contg. 25% Sb deposit first on freezing a solid soln. of about 50 at. % Sb, which by chem. methods of examn. may appear like a compd., SnSb . Prolonged annealing softens the Sn_3Sb_2 crystals, and lowers the anti-friction value of the alloys.

GEO. F. COMSTOCK

Surface cracking of rails in service. SABOURET. *Rev. métal.* 25, 169-71(1928).—Controversial with Viteaux (C. A. 22, 1940). H. VITEAUX. *Ibid* 172.—Reply to Sabouret.

A. PAPINEAU-COUTURE

Embrittlement of boiler plate. SAMUEL W. PARR AND FREDERICK G. STRAUB. *Univ. of Illinois, Eng. Expt. Sta. Bull.* No. 177, 71 pp.(1928).—A résumé of 3 years' work on embrittlement, contg. information concerning failures due to this cause and data obtained from lab. and plant tests. Embrittlement was caused by the combined action of stress and chem. attack brought about by the presence of NaOH in the boiler. Photomicrographs showed cracks to be intercryst. The effects of heat treatment, steam pressure and temp. stress, hydroxyl-ion concn., and NaCl on the rate of embrittlement were studied. Sulfates in the water in the proper ratio to the Na_2CO_3 content will prevent embrittlement. Phosphates, tannates, chromates, acetates, etc., will also inhibit attack. Methods of treatment are given.

J. K. ROBERTS

Spectrographic researches on the stamping of sheets. JEAN J. TRILLAT. *Compt. rend.* 186, 1535-6(1928).—X-ray spectrography of cold steel stampings from which a specimen is punched for examn. and thinned to a thickness of 0.12-0.16 mm. by etching with dil. HNO_3 gives an easily applicable examn. method. Grain structure, orientation and other changes in properties are given for specimens tested.

A. P. S.

Mass effect in the heat treatment of large forgings. I. J. A. JONES. *Metallurgist* (Suppl. to *Engineer* 145, No. 21), 70-2(1928).—"The properties of large masses can only be substantially improved by utilizing an alloy steel in which the transformations of the steel on cooling are retarded, so that efficient hardening is secured at comparatively slow rates of cooling." Tests are given of properly treated forgings of different compns. II. *Ibid* No. 26, 86-90.—Illustrations and data are given showing that lack of uniformity after heat treatment is greatest when the rate of cooling imposed by the mass of material approximates the crit. rate of cooling for hardening. Ni steel, itself unsuitable for large forgings, becomes satisfactory when W is added.

D. B. DILL

Influence of welding on structure. A. HILPERT. *Z. Ver. deut. Ing.* 71, 1449-58 (1927); *Science Abstracts* 31B, 9.—The influence of the various methods of welding metals, especially the welding of articles of large size, on the form of the welded parts is described. The various methods of welding, arc, oxyhydrogen, elec., but and pres-

sure welding and the ordinary smiths' welding, are discussed and the results contrasted. Welds of great size on bridge girders, storage tanks, water-pipes and dynamo housings are described, and the alternative methods of construction are considered. H. G.

The welding of aluminum. H. HOLLER. *Apparatebau* 40, 145-54(1928); cf. C. A. 22, 211.—Directions are given for gas and hammer welding, with 30 cuts and 2 tables of the phys. properties of welded app. J. H. MOORE

Magnets control welding arc. A. F. DAVIS. *Iron Age* 121, 1810-11(1928).—The superimposing of a strong magnetic field on the flame of a C welding arc appears to give the arc a gyratory motion easier for the welder to control than the normal arc. The microstructure of the weld metal made by the controlled arc on $\frac{1}{2}$ " plates is very similar to that of a highly refined low-C steel. The cost of welding $\frac{1}{2}$ " plates by this method ranges from 3 to 7 cents per ft. DOWNS SCHAAF

X-ray diffraction measurements in the systems iron-silicon iron-chromium and iron-phosphorus. CARL KREUTZER. *Z. Physik* 48, 556-66(1928).—The x-ray method of Debye and Scherrer was used to study the effect of the addns. of Si and Cr upon the $\alpha \rightleftharpoons \gamma$ and $\gamma \rightleftharpoons \delta$ transformations in pure Fe. The elements and alloys, in the form of wires, were heated to various temps in a vacuum camera. With rising Si content in Fe the range of temps. over which γ -Fe can exist narrows down. No γ -Fe structure (face-centered cubic) was observed at any temp in Fe contg. over 2.5% Si. The same was true of Fe contg. over 15% Cr. In the temp.-equil. diagram of the latter system the line representing the A_1 transformation should meet the one representing the A_2 transformation at 15% Cr. The non-existence of a compd. between Cr and Fe is easily seen from the diffraction patterns. It was, however, not possible to state definitely whether Fe and Cr show limited miscibility or form a complete series of solid solns. More precise measurements, to settle this matter, are now in progress. The röntgenographic examn. of the system Fe-P at room temp. shows solid soln. of P in Fe up to 1.7% P. Definite diffraction patterns establish the existence of Fe_3P , Fe_2P and still another compd. of higher P content. WILLIAM F. EHRET

Operating open-hearth furnaces. ARTHUR L. STEVENS (to Arthur L. Stevens Corp.). U. S. 1,677,664, July 17. In operations such as melting steel a neutral atm. is created in the open-hearth furnace and the pressure is automatically maintained at substantially atm. pressure. App. is described.

Continuous furnace for carbonizing metal articles. WILLIAM M. HEPBURN (to Surface Combustion Co.). U. S. 1,677,136, July 17.

Grease-melting furnace for use with hot rolls of tin mills. WM. C. LLOYD AND ARTHUR R. MCARTHUR (to American Sheet and Tin Plate Co.). U. S. 1,675,813, July 3.

Furnace for heat treatment of packs of metal sheets and plates. RUDOLPH W. STILER. U. S. 1,676,590, July 10.

Discharging and quenching apparatus for heat treating furnaces. FRANK T. COPE (to The Electric Furnace Co.). U. S. 1,675,795, July 3. The app. is suitable for treating automobile gears or other small articles.

Blast-furnace tuyère cooler construction. JAMES E. LOSE. U. S. 1,675,811, July 3.

Wrought iron. ROBERT D. PIKE. U. S. 1,675,867, July 3. Wrought iron comprising layers of electrolytic iron in cathode sheets with intervening laminae of slag is formed by stacking the sheets with intervening slag-forming material and heating to effect welding.

Steel for bearings. HENRY T. CHANDLER. U. S. 1,676,384, July 10. A steel rod contg. free carbides in such proportion that the rod is unsuitable directly for making roller bearings is rendered suitable for this purpose by twisting so that the lines of segregation of the carbides extend helically.

Increasing the permeability of silicon steel. JOHN C. KARCHER (to Western Electric Co.). U. S. 1,677,139, July 17. Si steel is heated to 1000-1250°, cooled at a rate of not more than 10° per min., reheated to 550-800° and then cooled more slowly than quenching in water but faster than quenching in air, e. g., by effecting the cooling between Cu plates.

Permanent magnets. JOHN H. WHITE. U. S. 1,675,872, July 3. Molten magnet steel is poured into a chilled mold and the casting formed afterward is magnetized.

Permanent magnets. LESLIE E. HOWARD and ALLEN D. PORRS (to Simonds Saw and Steel Co.). U. S. 1,677,674, July 17. Magnets are formed of W steel contg. V 0.05-1.00%.

Composite metal sheets. F. KRUPP A.-G. Brit. 280,518, Nov. 11, 1926. Billets of 2 metals such as mild steel and Ni-Cr steel are assembled with their contacting surfaces scoured or otherwise prepd. for welding, and with kaolin between rough surfaces of like contacting metals which are not to be united, to prevent union of the latter, and the assembled materials are subjected to heating and rolling.

Heat-resisting alloy. NOAK V. HYBINETTE. U. S. 1,675,709, July 3. An alloy which is resistant to high temps and is suitable for making castings contains Ni 5-10, Cr 15-25, C 1-2, Al 0.5-2% and the remainder is mainly Fe.

Alloys of aluminum containing copper. ALFRED G. C. GWYER and HENRY W. L. PHILLIPS (to British Aluminum Co., Ltd.). U. S. 1,676,856, July 10. About 0.1-0.3% of Ca or other alk. earth metal is added to a molten alloy which contains at least about 6% Cu and at least about 50% Al, in order to give an increase of elongation.

Aluminum alloys. NOAK V. HYBINETTE. U. S. 1,675,708, July 3. An alloy which is suitable for making cooking utensils contains Al about 90% together with Fe 0.5-2, Ni 3-6% and at least one of the metals Cr, W and Mo in quantity below 1% (suitably about 0.2-1%).

Determining the composition of copper and zinc alloys. MICHAEL POLANYI and STEPHAN VON BOGDANDY. U. S. 1,676,709, July 10. See Brit. 268,306 (C. A. 22, 1130).

Alloys of iron, copper, chromium, etc. BYRAMJI D. SAKLATWALLA. U. S. 1,676,929, July 10. Fe alloys which are resistant to corrosion contain C 0.1-2, Cr 8-25, Cu 0.5-5 and Si 1-3%.

Iron alloys for electric resistances. W. E. RUDER (to British Thomson-Houston Co., Ltd.). Brit. 280,537, Nov. 9, 1926. Fe is alloyed with Al 2-6 and Cr 10-15% Si and Mn up to 1% each and C up to about 0.1% also may be present.

Lead alloys. REGINALD S. DEAN and WM. E. HUDSON (to Western Electric Co.). U. S. 1,675,644, July 3. An alloy which may contain Pb and Sb 2.25% is repeatedly raised to the temp. at which the max. quantity of solute material present will enter solid soln. and between heating stages it is rolled and stamped or otherwise worked; the alloy is then quenched and aged, and is suitable for storage battery grids.

Magnesium and its alloys. I. G. FARBENIND. A.-G. Brit. 280,530, Nov. 13, 1926. In a modification of the processes for purifying Mg or its alloys as described in Brit. 182,948 (C. A. 16, 4180) and Brit. 219,287 (C. A. 19, 461), finished products are made contg. up to 0.1% Ca and up to 0.4% Mn. Ca and Mn chloride or other Mn compd. may be added to the salt melts during the process, or a Ca-Mn or other Mn alloy or metallic Mn may be added.

Magnetic alloy. GUSTAV W. ELMEN (to Western Electric Co.). U. S. 1,675,884, July 3. A magnetic material having a higher permeability than Fe at low magnetizing forces comprises Ni 2 and Cu 1 part.

Nickel alloys. RUSSELL FRANKS and BURNHAM E. FIELD (to Haynes Stellite Co.). U. S. 1,675,798, July 3. Alloys which are suitable for "high-speed" tools comprise Al 3-5, Si 3.5-6, W 5-12, Zr 6-12, B 1% or less, the remainder being principally Ni.

Restricting corrosion of magnesium and its alloys. ARTHUR C. ZIMMERMAN. U. S. 1,677,667, July 17. The metal is treated with a soln. of H_2PO_4 until a protective coating of Mg phosphate is formed on the surface.

Bonding bearing metals. FREDERICK C. MATHISON (one-third to Casper L. Redfield). U. S. 1,677,354, July 17. In order to bond a bearing metal having a Pb base, to an Fe or steel body, the latter is coated with Cu and then with Sn and the bearing metal is deposited by the babbitting process on the Sn-coated surface.

Coating ferrous metal with zinc. JOSEPH G. FITZ GERALD (to Central Alloy Steel Corp.). U. S. 1,675,646, July 3. The metal to be coated is heated to about 450-500° and coated in a molten spelter bath to produce a tight coat, the character of which may be controlled by the cooling after coating. An app. is described.

Coating other materials with platinum. NAAMLÖÖZE VENNOOTSCHAP PHILIPS' GLOEILAMPENFABRIEKEN. Brit. 280,697, Oct. 29, 1926. W or Ni wires for cathodes, etc., are coated with Pt by heating in an atm. contg. carbonyl platinum chloride or other suitable volatile Pt compd.

Galvanizing. THEODORE A. DISSEL (to Cameron Appliance Co.). U. S. 1,675,926, July 3. In galvanizing small articles, a flux such as NH_4Cl is vaporized and the vapor is passed through a mass of the hot Zn-coated articles, to effect uniform action. An app. is described.

Metallizing nonmetallic surfaces. A. I. G. WARREN and PRECIOUS METAL INDUSTRIES, LTD. Brit. 280,651, Aug. 24, 1926. Bakelite or other non-metallic material, while in finely divided or plastic condition, is impregnated with S or a S compd. which will combine with a compd. of Au, Ag or other metal subsequently applied to the surface of articles made from the material, and after application and reaction of the metal compds. the reaction products are reduced to metallic state on the surface by electrolytic or other action.

Apparatus for detinning tinned scrap. M. A. ADAM. Brit. 277,127, June 16, 1926.

Gas for cutting and welding with oxygen. JAMES R. ROSE (to Carbo-Oxygen Co.). U. S. 1,676,871, July 10. A gas is used contg. at least about 80% H, at least about 10% CH₄, at least about 1.5% of heavier gaseous hydrocarbons and not materially more than 5% CO. Cf. C. A. 21, 2117.

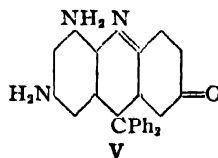

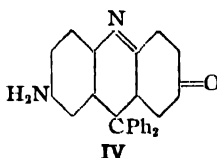

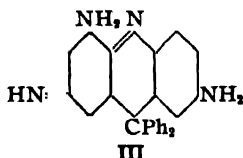

Composition for use in soldering or welding aluminum. WILHELM REUSS. U. S. 1,675,664, July 3. A mixt. of equal quantities of borax, H₃BO₃ and KOH is used as a flux.

Flux for welding cast iron. COLIN C. MARYAN (to General Electric Co.). U. S. 1,676,988, July 10. Fe₂(CO₃)₃ 4, NH₄Cl 12, Na borate 16, NaHCO₃ 20 and NaCl 12 parts.

10—ORGANIC CHEMISTRY

CHAS. A. ROULLIER AND CLARENCE J. WEST

Synthesis of carbazines. IV. HENRI GOLDSTEIN AND JEAN VAYMATCHAR. *Helv. Chim. Acta* 11, 245-9(1928); cf. C. A. 22, 1590.—Me 4,6,4'-triaminodiphenylamine-2-carboxylate on treatment with PhMgBr (I) gives a carbinol which rearranges to give 2,5,7-triaminodiphenylcarbazine (II). II on oxidation yields 2,5-diaminodiphenylcarbazine (III), which is identical with the compd. described by Kehrman, Goldstein and Tschudi (C. A. 13, 3178), proving that the formula assigned by them is correct. This synthesis may be used to prep. aminocarbazones, e. g., the Me ester of 4-amino-4'-hydroxydiphenylamine-2-carboxylic acid with I forms 2-amino-7-hydroxydiphenylcarbazine, which on oxidation gives 2-aminodiphenylcarbazone (IV). This confirms the formula assigned this compd. by K. and T. (C. A. 19, 1280; 20, 1801-2). Me 4,6-diamino-4'-hydroxydiphenylamine-2-carboxylate on similar treatment yields 2,4-diaminodiphenylcarbazone (V), m. 227°. This compd. is totally different from that described by K. and T. (C. A. 19, 1280).

HELEN COLLINS

Some derivatives of anthranilic acid. IV. HENRI GOLDSTEIN AND JEAN VAYMATCHAR. *Helv. Chim. Acta* 11, 239-45(1928); cf. C. A. 22, 1531.—2,3,5-Cl(O₂N)₂-C₆H₃CO₂H (I) condensed with *p*-C₆H₄(NH₂)₂ yields 4,6-dinitro-4'-aminodiphenylamine-2-carboxylic acid, m. 274°; on reduction and esterification, methyl 4,6,4'-triaminodiphenylamine-2-carboxylate, m. 151° is obtained. I with 4-amino-1,3-diacetamidobenzene, m. 218°, gives 4,6-dinitro-2',4'-diacetamidodiphenylamine-2-carboxylic acid (II), m. 255°. G. and V. were unsuccessful in their attempt to transform II into Me 4,6,2',4'-tetraminodiphenylamine-2-carboxylate. 2,5-Cl(O₂N)₂-C₆H₃CO₂H with *p*-H₂NC₆H₄OH in the presence of a Cu catalyst forms 4-nitro-4'-hydroxydiphenylamine-2-carboxylic acid, m. 210°; on reduction 4-amino-4'-hydroxydiphenylamine-2-carboxylic acid, 213° is obtained; Me ester, m. 164°. Me 4,6-diamino-4'-hydroxydiphenylamine-2-carboxylate, m. 162°, also was prepd.

HELEN COLLINS

Formation and properties of dithio ketones and dithio ethers. IV. Interaction of sulfur monochloride with organic compounds containing the reactive methylene group. KUNERJI G. NAIK AND YESHWANT N. BHAT. *Quart. J. Indian Chem. Soc.* 4, 525-30 (1927); cf. C. A. 17, 542.—S₂Cl₂ reacts with *N*-substituted derivs. of CH₂(CONH₂)₂ to form dithio ketones, and with *N*-substituted derivs. of CHMe(CONH₂)₂ to form dithio ethers. CH₂(CONH₂)₂ (2 g.) in 30 cc. dry C₆H₆ with 2 g. S₂Cl₂ refluxed 3 hrs., filtered and washed with dry petroleum gave a dithio ketone, C₇H₁₃N₂O₂S₂, shrinks at

186°, m. 202°. $\text{CH}_2(\text{CONHPr})_2$ gives a *dithio ketone*, $\text{C}_9\text{H}_{16}\text{N}_2\text{O}_2\text{S}_2$, shrinks 172°, m. 180°. $\text{CH}_2(\text{CONH-iso-Bu})_2$ gives a *dithio ketone*, $\text{C}_{11}\text{H}_{20}\text{N}_2\text{O}_2\text{S}_2$, shrinks 196°, m. 202°. *N,N'*-Diheptylmalonamide (12 g. from 11.5 g. $\text{C}_7\text{H}_{15}\text{NH}_2$ and 8 g. $\text{CH}_2(\text{CO}_2\text{Et})_2$, let stand for 24 hrs. in a sealed tube and then heated 7 hrs. at 125–30°), m. 132°. With S_2Cl_2 it gives the *dithio ketone*, $\text{C}_{17}\text{H}_{32}\text{N}_2\text{O}_2\text{S}_2$, m. 125°. *m*-Malonotoluide gives the *dithio ketone*, $\text{C}_{17}\text{H}_{16}\text{N}_2\text{O}_2\text{S}_2$, shrinks at 158°, m. 180°; it forms a *tetranitro deriv.*, m. 166° (decompn.). $\text{CHMe}(\text{CONHC}_6\text{H}_4\text{Me-}m)_2$ gives the *dithio ether*, $\text{C}_{20}\text{H}_{18}\text{N}_2\text{O}_4\text{S}_2$, m. 187–8°. *N,N'*-Dibenzyl- α -methylmalonamide (from $\text{CHMe}(\text{CO}_2\text{Et})_2$ and PhCH_2NH_2), m. 142°. E. H.

Oxidation of hexane. MAX BRUNNER AND ERIC K. RIDEAL. Univ. Cambridge. *J. Chem. Soc.* 1928, 1162–70.—The process of oxidation of hexane bears a striking resemblance to the autoxidation of BzH . The temp. of initial combustion is not a characteristic of the hydrocarbon, for rapid combustion will set in after a period of induction at lower temps. During this period of induction slow autoxidation proceeds together with the formation of peroxides. The period of induction at constant temp. is greatly affected by the O pressure and by the presence of inhibitors, such as PhNH_2 , or of surface catalysts, such as pumice. The temp. coeffs. of the reactions proceeding in the induction period are high. The suggestion is made that the reactions involve the formation at catalytic surfaces of an active "moloxide" (cf. Grün, *C. A.* 14, 3416), which is subsequently converted into a more stable peroxide. The peroxide can react either in the gas phase or at the surface, but when the peroxide concn. reaches a critical value, chain propagation ensues, causing excitation and combustion of mols. coming into contact with the reaction centers of the chain. C. J. WEST

The Wurtz reaction. Factors involved in the preparation of octane. HARRY F. LEWIS, ROBERT HENDRICKS AND G. ROBERT YOHE. *J. Am. Chem. Soc.* 50, 1993–8 (1928).—The following facts are established regarding the action of Na upon BuBr: optimum yields are obtained with an excess of Na (not greater than 50 mol. %); a vol. of Et_2O 2.5 times that of the BuBr should be used; low temp. favors the production of octane; the rapidity of the reaction depends upon the fineness of the Na wire; traces of H_2O cut down the yield; agitation accelerates the reaction; MeCN has no positive action in the formation of octane; small quantities of octane are easily recovered from the reaction mixt. by distn.; larger quantities are best obtained after the Na is destroyed. Phys. consts. are given for mixts. of octane and BuBr (d. and n_D^{20}). Directions are given for the prepn. of octane in 65–70% yields. Butene and at least 2 higher satd. hydrocarbons are also formed; the b. ps. of the hydrocarbons suggest dodecane and hexadecane. C. J. WEST

Hydrocarbon synthesis from carbon monoxide and hydrogen. O. C. ELVINS. *J. Soc. Chem. Ind.* 46, 473–8T (1927).—The interaction of CO and H was investigated at atm. pressure and in presence of catalysts at temps. of the order of 280°. A catalyst prepd. from a mixt. of 60 parts of cobalt, 30 parts of CuO, and 45 parts of Mn oxide was used in conjunction with varying gas mixts. Contrary to the original statements of Fischer and Tropsch that only aliphatic hydrocarbons are formed by this reaction definite amts. of water-sol. oxygenated compds. and olefins were found among the reaction products. A detailed account of the exptl. work is given and the prepn. of the catalyst from pptd. hydroxides, by ignition of nitrates, and from fused oxides, is described. The size of the granule was also investigated from the point of view of the inherent fouling effect of the waxy products of reaction. B. C. A.

Normal aliphatic alcohols and aldehydes. LOUIS DESCOLLONGES. *Am. Perfumer* 23, 237–8 (1928).—It is very seldom that aldehydes and aliphatic alcs. are used to impart a characteristic odor to a bouquet, their function being rather to give more freshness, "waxiness," sweetness and blending power. As the mol. wt. of these substances increases, their odor becomes less fatty and more tenacious. The odor of C_{10} is decidedly fresh and fruity, this quality becoming more so as one goes up to C_{15} . The C_{10} and C_{11} alcs. and aldehydes are therefore more readily used than the lower homologs. Because of the great potency of these products, only very dil. solns., 1/100 for example, are recommended for trial; aldehydes are as a rule more powerful than alcs. Aliphatic aldehydes and alcs. judiciously used should therefore complete the fundamental note given by the ordinary constituents and afford to the perfumer valuable help. Octyl alc., occurring in lemon, heracleum and male-fern oils, has an odor somewhat similar to that of opoponax. Nonyl alc., detected in orange oil, possesses a rose-like note recalling citronellol but of more fatty quality; its use is therefore indicated in rose perfume and in cologne waters. Decyl alc. has a rather indefinable fresh odor with an orange touch, hence indicated in jasmine, rose, orange blossoms, lily of the valley, lilac and fancy perfumes. Undecylenic alc. is successfully used in toning down the

violent note of aldehydes. Dodecyl alc. imparts freshness and tenacity, possessing an odor similar to that of nerolidol, which it can advantageously replace in most cases. Octyl aldehyde, a constituent of lemon and orange oils, combines perfectly with jasmine note, giving freshness and "waxing" quality. Nonyl aldehyde combines well with rose, geranium and neroli perfumes. Decyl aldehyde, detected in Manila orange, neroli, orange, orris, cassie, coriander and lemongrass oils, possesses a medium volatility which enables it to play the part of stabilizer, its presence giving a constant tonality to bouquets as long as evapn. lasts. It is therefore indicated with Sicilian oils in cologne waters, as also to impart a touch of originality to fancy perfumes. Undecyl aldehyde has a fine rose-like odor and imparts to compds. the "wax" note proper to natural flower oils. It is very useful in rose rouge, lily of the valley, tuberose and narcissus perfumes. Dodecyl aldehyde combines well with orange oil and greatly improves it. Appropriate also in combinations of tuberose, jasmine, lily of the valley, lily and violet.

W. O. E.
Nitrosyl chloride and ketones. H. RHEINBOLDT AND O. SCHMITZ-DUMONT. *J. Am. Pharm. Assoc.* 17, 134-5 (1928); see *C. A.* 22, 1152. I. E. WARREN

Action of nitrous acid on amino compounds. I. Methylamine and ammonia. THOMAS W. J. TAYLOR. *J. Chem. Soc.* 1928, 1099-1105.—No reaction was observed between 0.05 *N* MeNH₂ and 0.05 *N* HNO₂, with or without 0.05 *N* H₂SO₄ during 2.5 hrs. A fairly rapid reaction occurs with 0.1 *N* HNO₂, 1 mol. HNO₂ disappearing for each mol. of MeNH₂, the mean value of *k* at 25° is 1.14 (normality⁻², min.⁻¹). KCl diminishes the velocity. The reaction is increased by MeNH₂·HCl or Ba(NO₂)₂. The effect of H₂SO₄ was also studied. NH₃ (0.05 *N*) at 25° does not react with 1 equiv. of HNO₂ but reacts with 2, the velocity coeff. being of the order of 0.48; the velocity is lowered by addn. of mineral acids and of KCl; the velocity is accelerated equally by equiv. amts. of either NH₄Cl or Ba(NO₂)₂.

C. J. WEST

The mechanism of the reactions accompanying the formation of Cadet's oil. AMAND VALEUR AND PAUL GAILLIOT. *Compt. rend.* 185, 956-8 (1927); cf. *C. A.* 22, 572, 573.—Heating of KOAc and H₃AsO₃ gives a complex mixt., Cadet's fuming arsenical liquid. Probably arsenic methyl (I) is first formed and leads to the formation of compds. more or less methylated which tend, upon heating, to give Me₃As (II), the most volatile of the series, and As, the least volatile. Cadet's oil consists of As, a black polymer of I, and a liquid which gives a red polymer (III) of I, II, (Me₂As)₂ (IV), (Me₂As)₂O (V), Me₂As₂ and Me₃As₂. I, prepd. by Auger's method, b₁₀ 190°, d₁₅ 2.159, m. 10°, is (AsMe)₃; it gives III spontaneously. I in a sealed tube gives at 200-50° As, II and IV. IV in a sealed tube gives at 200-50° As and II. Therefore the heating of I leads to the following reactions: 4AsMe → 2As + (Me₂As)₂, (Me₂As)₂ → [AsMe] + Me₃As. Also, 2Me₂As + AsMe → Me₇As₃ and Me₂As + 2AsMe → Me₃As₃. The presence of V in Cadet's oil is due to the classic reaction of KOAc and As₂O₃ or to the accidental oxidation of IV. I may be formed analogously from KOAc and As₂O, the latter resulting from the reduction of H₃AsO₃.

MARGARET W. MCPHERSON

Organic titanous compound and a new method for the preparation of solutions of titanous salts. DONALD W. MACCORQUODALE AND HOMER ADKINS. Univ. Wisconsin. *J. Am. Chem. Soc.* 50, 1938-9 (1928).—An org. tervalent Ti compd. has been prepd. in an impure state by the reduction with Na of an EtOH soln. of Et₃TiO₄; this dark blue compd. acts as a reducing agent and also dissolves in HCl or dil. H₂SO₄ to form titanous salts. The solns. so obtained are entirely free from Fe or other metallic or acidic impurities. An improved method for the prepn. of Et₃TiO₄ is given. C. J. WEST

Synthesis and purification of hexamethylenimine. A. MÜLLER AND A. SAUERWALD. *Monatsh.* 48, 727-32 (1927).—Treatment of α,β-dibromohexane (1 mol.) and *p*-MeC₆H₄SO₂NH₂ (1 mol.) with aq. alc. KOH affords *N-p-toluenesulfonylhexamethylenimine*, m. 72-4°, together with α,β-di-*p*-toluenesulfonamidohexane. Treatment of the former compd. with concd. HCl at 160° gives hexamethylenimine·HCl, m. 236° (cor.) (lit. 222°). Pure hexamethylenimine b₁₀ 138.0-8.2°, d₁₅ 0.8841, d₄²⁰ 0.8799, d₄²⁵ 0.8770, n_D²⁰ 1.4654; the following derivs. are described: chloroplatinate, decomp. 190-7° (cor.) (lit. 149° and 191°); chloroaurate, decomp. 206° (cor.); picrate, m. 146.5° (cor.) (lit. 85°); phenylthiocarbimide, m. 143° (cor.); the *Bz* deriv., m. 36° (cor.), when treated with PCl₅ yields α,β-diphenoxy-hexane m. 83-3.5° (cor.). *N,N*-Dimethylhexamethyleniminium iodide [chloroplatinate, decomp. 233° (cor.)], m. 265° (cor.) with slight decompn. (lit. 214-5°).

B. C. A.

Nonaldehyde from the tetradecenoic acid from sperm oil. ALFRED WAGNER. *Allgem. Öl-Fett-Ztg.* 24, 340-1 (1927).—Tetradecenoic acid, d₄²⁰ 0.9018, n_D²⁰ 1.4549, I value 107, was isolated from sperm-whale oil, and converted into the ozonide, which

on decompn. with water yielded nonaldehyde (semicarbazone, m. 80–84°; after purification with H_2SO_4 , semicarbazone, m. 100°; oxime, m. 64°). B. C. A.

Reactions relating to carbohydrates and polysaccharides. XIV. Polymerization of aldehydes. HAROLD HIBBERT, W. F. GILLESPIE AND R. E. MONTANNO. McGill Univ. *J. Am. Chem. Soc.* 50, 1950–5(1928); cf. C. A. 22, 2141.—This is a confirmation and extension of the work of Stepanov (C. A. 20, 362; 21, 731) on the bromoparaldehydes. CCl_3CHO (1 mol.) and 2 mols. Me_3CCHO give a mixed paraldehyde, $\text{C}_{12}\text{H}_{20}\text{O}_4$, m. 114–5°; it is very stable toward alkalis but decomps on continued boiling with H_2SO_4 ; a trace of concd H_2SO_4 acts as a catalyst. EtCHO gives, with a few drops of dry HCl as a catalyst, 35–40% of the compd $\text{C}_8\text{H}_{13}\text{O}_4\text{Cl}_3$, m. 62.5°. Me_3CCHO gives the compd. $\text{C}_{10}\text{H}_{17}\text{O}_4\text{Cl}_3$, m. 68.5–9° (39% yield). Attempts to prep. compds. involving 3 different aldehydes failed. XV. The isomeric benzylideneglycerols. HAROLD S. HILL, MYRON S. WHEELER AND HAROLD HIBBERT. *Ibid* 2235–42(1928); cf. Irving, Macdonald and Soutar, C. I. 9, 1468.—Condensation of 150 g. BzH and 120 g. $\text{C}_3\text{H}_8\text{O}_3$ by heating in CO_2 1 hr. at 145–55° and 30 min. at 165° gives 170 g. of a mixt. b_D 140–9°; purification gives 120 g. mixed glycerols, b_D 142–7°, d_4^{17} 1.19838, n_D 1.5400; soln. of 60 g. of this mixt. in 150 cc. ligroin (b. 60–70°) and 90 cc. C_6H_6 and cooling to –15°, gives 7 g. 1,3-benzylideneglycerol (I), m. 83.5°; distn. of the product from the mother liquors gives the 1,2-isomer (II), b_D 143–4°, d_4^{17} 1.1916, n_D 1.5389. The same products were also obtained with H_2SO_4 as a catalyst. By the 1st method, the ratio of II to I was 7.5:1; by the 2nd method, the ratio was 3:1. The Bz deriv. of I m. 103°; that of II is an oil. Methylation of I with MeI and Ag_2O gives the β -Me ether, m. 52° (31 g. from 54 g. I), hydrolysis gives 64% of β -Me glycerol ether, b_D 123°, d_4^{17} 1.1300, n_D 1.4505, which should prove a reference compd. of some importance. The Me deriv. of II was sepd. into 3 fractions, b_D 138–9°, 130–41°, 141–5°, n_D 1.5128, 1.5135, 1.5159; hydrolysis of the lowest boiling fraction gave 87% of α -Me glycerol ether, b_D 110°, d_4^{17} 1.1202, n_D 1.4449, corresponding with the properties of the compd. of I, M. and S. Hydrolysis of the highest boiling fraction indicated the presence of some of the β -Me ether. When I is treated with a trace of dry HCl and heated at 100° for 1 hr., the ratio of II to I is 5:1; starting with II, the ratio is 5.5:1. XVI. Separation and identification of the isomeric ethylideneglycerols. HAROLD S. HILL, ALLAN C. HILL AND H. HIBBERT. *Ibid* 2242–9.—On passing 45 l. of C_2H_2 through a mixt. of 8 g. H_2SO_4 , 8 cc. concd. H_2SO_4 and 184 g. $\text{C}_3\text{H}_8\text{O}_3$ at 70°, there results 234 g. of a mixt. of ethylideneglycerols, b_D 86–101°; from 276 g. $\text{C}_3\text{H}_8\text{O}_3$, 5 cc. 50% H_2SO_4 and 144 g. $(\text{HCHO})_3$ at 100°, there results 233 g. of a mixt. b_D 79–89°. While these mixts. can be partially sepd. by fractional distn., they are best sepd. through the benzoates; the following products were isolated: 1,3-ethylideneglycerol (I), b_D 52°, d_4^{17} 1.1477, n_D 1.4532; 1,2-isomer (II), b_D 68–70°, d_4^{17} 1.1243, n_D 1.4413; Bz deriv. of I, m. 86°; of II, b_D 144–5°, d_4^{17} 1.1618, n_D 1.5145; Me ether of I, b_D 80°, d_4^{17} 1.0705, n_D 1.4375; of II, b_D 50–8°, d_4^{17} 1.0224, n_D 1.4177. The ratio of I to II in the C_2H_2 method of prepn. is 1:1.8; in the $(\text{HCHO})_3$ method, 1:4. The structure of I and II is established by hydrolysis to the corresponding α - and β -Me ethers of glycerol. C. J. WEST

Catalysis in the conversion of allyl alcohol and acrolein into propionaldehyde. PAUL E. WESTON AND HOMER ADKINS. Univ. Wisconsin. *J. Am. Chem. Soc.* 50, 1930–5(1928).—The behavior over a ZnO catalyst of $\text{CH}_2=\text{CHCH}_2\text{OH}$ (I) and mixts. of I with $\text{CH}_2=\text{CHCHO}$ (II) has been investigated as has also the reaction over Al_2O_3 of II and PrOH . All of the exptl. results indicate that the formation of EtCHO from I over ZnO results at least in part from the reaction of I with II and not through the hydrogenation of II nor through the intramol. rearrangement of I. C. J. WEST

Simpler derivation of the Cook formula for the determination of the acetyl value of fats and oils. WM. RIEMAN III AND ALFRED T. HAWKINSON. Rutgers Univ. *J. Am. Chem. Soc.* 50, 2311–2(1928).—A new method is given for the derivation of the formula $A = (S' - S)/(1 - 0.00075S)$. C. J. WEST

Purification of palmitic and stearic acids. A. I. WILKIE. *J. Soc. Chem. Ind.* 46, 471–2T(1927).—Reasonably pure palmitic and stearic acids can be obtained by fractional distn. under diminished pressure of a mixt. of the Et esters through a column of the Dufton type, 150 cm. long, maintained at a uniform const. temp. The appropriate fractions are hydrolyzed. B. C. A.

Oxidation of unsaturated acids by means of chlorates in presence of osmium. I. Oxidation of crotonic, cinnamic, oleic and elaidic acids and reciprocal transformation of oleic and elaidic acid. S. S. MEDVEDEV AND E. N. ALEKSEVA. *Papery Karpov*

Chem. Inst. Bach Memorial Vol. 1927, 128-42.—Hofmann's method (C. A. 7, 999, 3088; 8, 3297; 10, 303) was used by M. and A. for obtaining oxidation products of crotonic, cinnamic, oleic and elaidic acids. A mixt. of 9 g. *crotonic acid*, 15 cc. of 50% NaClO_3 , 48 cc. water, 3 g. NaHCO_3 and 3 cc. of 1% OsO_4 was heated on a water bath at 80°. In the course of 10 hrs. 96% of the theoretically needed O was utilized (judged by the extent of transformation of NaClO_3 into NaCl). The following 2 reactions took place: (1) $\text{MeCH:CHCO}_2\text{H} + 0.5\text{O}_2 + \text{H}_2\text{O} = \text{MeCH(OH)CH(OH)CO}_2\text{H}$; (2) $\text{MeCH:CHCO}_2\text{H} + 2\text{O}_2 = \text{AcOH} + (\text{CO}_2\text{H})_2$. Dihydroxybutyric acid and 1.2 g. $(\text{CO}_2\text{H})_2$ were thus obtained. Ten g. *cinnamic acid*, 3.4 g. Na_2CO_3 , 15 cc. 50% NaClO_3 , 2 cc. 1% OsO_4 and 65 cc. water were treated approximately in the same way as above. The products obtained were 50% phenylglyceric acid ($\text{C}_6\text{H}_5\text{O}_4$) and 20% BzH . $(\text{CO}_2\text{H})_2$ was not formed. Ten g. *oleic acid*, 3.5 g. Na_2CO_3 , 8 cc. 50% NaClO_3 , 3 cc. 1% OsO_4 and 154 cc. water were heated in a water bath 66 hrs., but the oxidation stopped after the 1st 50 hrs. when only 48% of the theoretically needed O was obtained and the reaction did not continue even on adding new amounts of NaClO_3 and OsO_4 . The products obtained were elaidic acid, m. 46-7°, and 3.5 g. of 9,10-dihydroxystearic acid, $\text{C}_{18}\text{H}_{34}\text{O}_4$, m. 134°. Stereoisomeric dihydroxystearic acid, m. 95°, was absent. *Elaidic acid* (10.5 g.), 10 cc. 50% NaClO_3 , 1.2 g. NaHCO_3 , 10 cc. 1% OsO_4 and 150 cc. water were heated on a water bath 100 hrs.; 91% of the O theoretically needed for oxidation had been used up. The products of reaction were oleic acid, m. 12-3°, and 4.5 g. low-melting 9,10-dihydroxystearic acid. The stereoisomeric variety of the latter acid, which m. 132°, was not obtained. By oxidizing in the same manner a mixt. of oleic and elaidic acids, both the high-melting and the low-melting varieties of dihydroxystearic acid were obtained. *Conclusions.*—(1) The high-melting dihydroxystearic acid is obtained as a product of oxidation of oleic acid, whereas its low-melting stereoisomer is obtained by oxidation of elaidic acid; the result is the same when KMnO_4 is used as oxidizing agent. (2) The reciprocal transformation of oleic and elaidic acids is a very important fact from the point of view of considerations on the stereochem. structure of these 2 acids, since it unsettles the question whether a *cis*- or a *trans*-formula should be attributed to oleic acid; it has hitherto been thought that while oleic acid can be transformed into the more stable elaidic acid, the inverse transformation was not feasible.

BERNARD NELSON

Isobleic acids. K. H. BAUER AND J. MITSOTAKIS. Univ. Leipzig. *Chem. Umschau Fette, Oele, Wachse u. Harze* 35, 137-9 (1928).—Isobleic acids may have their double C bond between any C atoms except at the 9,10-position, which is reserved for the normal acid. They are solid at room temp. Unsuccessful attempts to isolate isobleic acid from the solid acids after hydrogenating peanut oil, caused B. and M. to ozonize the liberated mixed acids, then to ext. the free acids and acid esters of the di- CO_2H acids with dil. Na_2CO_3 , liberate the acids with the H_2SO_4 and distil them finally with steam. They obtained a decamethylenedicarboxylic acid m. 123-4°, identified by ultimate analysis; also a small quantity of azelaic acid m. 106°, and the volatile caproic acid, identified by b. p., sapon. no., ultimate analysis and analysis of its Zn salt. These products point to the presence of 12,13-isobleic acid and this acid probably resulted from the satn. of the 9,10-double bond in linolic acid, leaving the 12,13 double bond intact.

P. ESCHER

Reaction of bromine with aliphatic acids. II. The relative speeds of bromination of acetyl bromide and acetyl chloride. HERBERT BEN WATSON. Univ. Coll. of North Wales. *J. Chem. Soc.* 1928, 1137-41; cf. C. A. 20, 42.—With AcBr in excess, the value of $k_1 = (1/t) \log [a/(a-x)]$ shows a progressive decrease, but const. are obtained if allowance is made for the "fixing" of Br in the equil. $\text{HBr} + \text{Br}_2 \rightleftharpoons \text{HBr}_3$. Small quantities of FeCl_3 or H_2SO_4 do not accelerate the reaction but IBr is a catalyst. Br reacts with AcCl more slowly than with AcBr . At 25°, with the concns. employed, the velocity is proportional to the concn. of Br during the 1st half of the reaction, extensive perbromide formation being prevented by the reaction $\text{HBr} + \text{AcCl} = \text{AcBr} + \text{HCl}$; the values of k_1 increase, however, as would be expected, when the quantity of AcBr becomes considerable. A CO_2H acid reacts with the bromide of another acid, $\text{RCO}_2\text{H} + \text{R}'\text{COBr} = \text{RCOBr} + \text{R}'\text{CO}_2\text{H}$; on distg. mol. quantities of BrCH_2COBr and AcOH , the 1st fraction is AcBr ; the f. p. of a soln. of the same acid bromide in AcOH indicated that the greater part had reacted after 1 hr. at 25°.

C. J. WESS

Effect of the cyanide group on the basicity of aliphatic amines as determined in water and alcohol solutions. T. D. STEWART AND VIVIEN COOK. Univ. Calif. *J. Am. Chem. Soc.* 50, 1973-83 (1928).—The basic dissocn. consts. of $\text{Et}_3\text{NCH}_2\text{CN}$ and of $\text{Et}_3\text{NCHPhCN}$ in H_2O are 1.0×10^{-10} and 1.7×10^{-11} , resp. In EtOH , the acidic dissocn. consts. of their salts (chlorides) are 3.4×10^{-4} and 5.2×10^{-4} , resp., while

those of $\text{Me}(\text{Et}_2\text{N})\text{CHCN}$ and of $\text{Me}_2\text{C}(\text{NEt}_2)\text{CN}$ in EtOH are 3.4×10^{-5} and 2×10^{-6} , resp. The base strength of some amino ethers in EtOH has been recalcd. Some of the factors which det. the apparent change in relative base strength with change of solvent are discussed.

C. J. WEST

Preparation of α,η -dihydroxyheptane (heptamethylene glycol) and α,η -dibromo- η -heptane. A. MÜLLER AND E. RÖTZ. *Monatsh.* **48**, 733-6(1927).—Reduction of Et pimelate by the Bouveault and Blanc method affords heptane- α,η -diol (60% yield) b_D^{20} 148-9° [phenylcarbimide, m. 137° (cor.); cf. Dionneau, *C. A.* **9**, 2057]. Treatment of the glycol with HBr at 130-40° yields α,η -dibromoheptane, b_D^{20} 132°, in 74% yield.

B. C. A.

Lower glycerides of palmitic acid. W. BRASH. *J. Soc. Chem. Ind.* **46**, 481-2T (1927).—The lower glycerides of palmitic acid were prepd. by heating Pb palmitate with the corresponding glycerol chlorohydrin. It was found impossible to prep. the β -monochlorohydrin in a satisfactorily pure condition. The m. ps of the glycerides obtained are: α -monopalmitin 68°, α,γ -dipalmitin 61.5°, α,β -dipalmitin 68.5°. B. C. A.

A general reaction of amino acids. H. D. DAKIN AND R. WEST. Scarborough-on-Hudson. *J. Biol. Chem.* **78**, 91-105(1928).—When α -amino acids are warmed with Ac_2O and pyridine, CO_2 is evolved and 2 Ac groups are introduced, one attached to N and one to C. The compds. formed are derivs. of acetylaminooacetone and have the general formula $\text{RCH}(\text{NHAc})\text{COMe}$. The following facts are adduced to substantiate this formula: In the cases of tyrosine, phenylalanine and leucine, in which the reaction goes virtually to completion, it was possible to show that 1 mol. of CO_2 was evolved for each mol. of the acid entering into the reaction. The presence of an Ac group attached to N was indicated by hydrolysis. Strong positive CHI_3 and nitroprusside reactions, and the formation of benzylidene derivs., on condensation with BzHI , indicate that the compd. is a Me ketone. The position of the latter group is shown by the fact that glycine, β -trimethylalanine and phenylaminooacetic acid undergo the reaction. After removal of the Ac group attached to N, alkali in the presence of HgCl_2 converts the compds. into pyrazine derivs., indicating their relation to acetylaminooacetone. By the action of $\text{O}_2\text{NC}_6\text{H}_4\text{NHNH}_2$ in hot dil. H_2SO_4 soln. the new ketones are converted into the characteristic bisnitrophenylhydrazones of glyoxals. Proline, alkylamino acids and α -aminohydroxy acids, do not react like the α -amino acids but undergo simple acetylation. The general reaction is considered as resulting by loss of CO_2 from intermediate β -ketonic acids. The pyridine is catalytic in its function. Lutidine, collidine and nicotinic acid are also effective as catalysts but PhNMe_2 and quinoline are not. The general reaction is shared by α -halogen acids and some unsubstituted acids like $\text{PhCH}_2\text{CO}_2\text{H}$ which gives MeCOBz . The biol. significance of the reaction is discussed and its possible use for the prepn. of pharmacol. active substances indicated. A. G.

Reciprocal action between α -oxides and esters of amino acids. II. A. KIPRIANOV. *Inst. angew. Chem. Charkov. Ukrainskii Khim. Zhurnal* **2**, 236-49(1926); *Chem. Zentr.* 1927, I, 2654-5, cf. *C. A.* **21**, 2467. Ethylene oxide (I) reacts easily (1 hr. on the water bath or 48 hrs. at room temp.) with $\text{H}_2\text{NCH}_2\text{CO}_2\text{Et}$ or $\text{MeCH}(\text{NH}_2)\text{CO}_2\text{Et}$. The formation of *N*-monosubstituted and *N*-disubstituted esters was to be expected, e. g., $\text{HOCH}_2\text{CH}_2\text{NHCH}_2\text{CO}_2\text{Et}$ and $(\text{HOCH}_2\text{CH}_2)_2\text{NCH}_2\text{CO}_2\text{Et}$, but actually EtOH was liberated and only *N*-disubstituted acids were isolated. When equimol. parts of I and of the amino acid ester were used, their yield reached approx. 30%, with no other products, but with excess I the yield is greatly increased. The primary reaction product is, however, not the *N*-disubstituted acid, but very probably its morpholine which is hydrated only by treatment of the reaction product with water. I (10 g.) and $\text{H}_2\text{NCH}_2\text{CO}_2\text{Et}$ (22 g.) let stand 48 hrs. in a sealed tube, the EtOH (4.5 g.) distd. off and the residual oil (II) let stand in the air, yields on recrystn. from EtOH , approx. 4 g. of dihydroxydiethylaminooacetic acid, $(\text{HOCH}_2\text{CH}_2)_2\text{NCH}_2\text{CO}_2\text{H}$ (III), m. 193° (decompn.), sweet taste. *Picrate*, $\text{C}_6\text{H}_5\text{O}_2\text{N}_2\text{C}_6\text{H}_3\text{O}_7\text{N}_3\text{H}_3\text{O}$, m. approx. 95°. *Cu salt*, $\text{Cu}(\text{C}_6\text{H}_5\text{O}_2\text{N})_2\cdot\text{H}_2\text{O}$, blue. *Dibenzate*, soft and readily fusible, decompd. by warming with EtOH . On dry distn. of the uncrystallizable part of II or of pure III, 1-hydroxyethyl-3-morpholine, $\text{HOCH}_2\text{CH}_2\text{N}(\text{CH}_2)_3\text{CO}_2\text{CH}_2\text{CH}_3$ (IV), is formed, b_D^{20} 175-6°, miscible

in all proportions with EtOH and with water; exposed to moist air it becomes covered with a cryst. coating of III. III is likewise formed in aq. IV, the yield being about 71% after 10 min. at room temp. and 99% on long standing. A small proportion of IV remains, however, in equil. with III, about 2.8% at 90-100° and 0.7% at 0° (cf. *Ann.* **307**, 199). Evapn. of III with PtCl_4 and HCl on a water bath ppts. the chloroplatinate of IV, $(\text{C}_6\text{H}_5\text{O}_2\text{N})_2\cdot\text{H}_2\text{PtCl}_6$, red, m. 190° (decompn.). $(\text{HOCH}_2\text{CH}_2)_2\text{NCH}_2\text{CO}_2\text{Et}$ (24.5 g.) heated with I (30 g.) in a sealed tube at 90°, excess I sepd., the residue (V)

dild. with water, evapd. on a water bath in an air current, and recrystd. from EtOH, yields 87% of α -[dihydroxydiethylamino]propionic acid, $(\text{HOCH}_2\text{CH}_2)_2\text{NCHMeCO}_2\text{H}$ (VI), m. 136° (decompn.). Picrate, $\text{C}_7\text{H}_{15}\text{O}_4\text{N}_3\text{C}_6\text{H}_3\text{O}_7\text{N}_3\cdot\text{H}_2\text{O}$, yellow, m. $80-5^\circ$. Cu salt, $\text{Cu}(\text{C}_7\text{H}_{14}\text{O}_4\text{N}_2)_2\cdot 5\text{H}_2\text{O}$, lilac color. Di-Bz deriv., soft, m. $42-3^\circ$. 1-Hydroxyethyl-2-methyl-3-morpholine, $\text{HOCH}_2\text{CH}_2\text{N}(\text{CHMe.CO.O.CH}_2\text{CH}_2)_2$ (VII), identical with V,

is also formed by the dry distn. of VI, b_s $171-2^\circ$, changes on exposure to air into VI, remains in water in equil. with VI, 96.5% of VII being hydrated at 100° and 99% at 0° . Chloroplatinate of VII, $(\text{C}_7\text{H}_{13}\text{O}_3\text{N})_2\text{H}_2\text{PtCl}_6$, m. $179-80^\circ$ (decompn.). The picrate of VII is amorphous, and the methiodide is a yellow oil which gradually crystallizes.

C. C. DAVIS

Synthesis of 4-dimethylamino-2,3-butenic acid methylbetaine (crotonobetaine). WILHELM LINNEWEH. *Z. physiol. Chem.* **176**, 217-21 (1928); cf. *C. A.* **22**, 1956.—By treatment with anhyd. HCN for 80 hrs. in a sealed tube at $70-5^\circ$ epichlorohydrin was converted into $\text{ClCH}_2\text{CH}(\text{OH})\text{CH}_2\text{CN}$, the latter saponified and esterified by means of HCl and EtOH to $\text{ClCH}_2\text{CH}(\text{OH})\text{CH}_2\text{CO}_2\text{Et}$, and this in turn dehydrated to $\text{ClCH}_2\text{CH}=\text{CHCO}_2\text{Et}$ by distn. with P_2O_5 . Condensation of this chlorocrotonic ester with excess of alc. Me_3N and a trace of NaI by heating several hrs. in a sealed tube at 100° yielded crotonobetaine-HCl, m. $203-5^\circ$ (decompn.). Other derivs. prepd. from the betaine were Et ester chloroplatinate, decomp. $223-5^\circ$, chloroaurate, m. $215-7^\circ$; chloroplatinate, decomp. $221-2^\circ$, free base, decomp. $200-5^\circ$; picrate, m. $187-9^\circ$. Hydrogenation with Pd catalyst yielded γ -butyrobetaine, identified as the chloroaurate. The chloroaurate and the Et ester chloroplatinate have the same m. ps. as the corresponding derivs. of the base isolated from beef muscle, and the mixed m. ps. showed no depression. The position of the double bond in the natural base is thus definitely located, and the identity with crotonobetaine established. This is the first naturally occurring betaine to contain a double bond.

A. W. DOX

Rearrangement of peptide-like substances. XXV. The so-called arginylarginine of E. Fischer, an α,δ -bisguanidovaleric anhydride. LEONIDAS ZERVAS AND MAX BERGMANN. Kaiser-Wilhelm Inst. Lederforschung Dresden. *Ber.* **61B**, 1195-203 (1928); cf. *C. A.* **22**, 2356.—Fischer and Suzuki assigned to their "arginylarginine" (I), obtained by autocondensation of Me-d-arginine, a dipeptide structure only with reserve because it could not be converted back into arginine on even long boiling with acids and the N content of the nitrate, as detd. by the Dumas method, was always too high. Z. and B. have now found that it is not an anhydride, peptide or peptide anhydride of arginine but a racemized α,δ -bisguanidovaleric anhydride, $\text{H}_2\text{NC}(\text{NH})\text{NHCH}_2\text{CH}_2\text{CH}_2\text{CH}(\text{CO.NH.C}(\text{NH})\text{NH})$ (II). F. and S.'s picrate, m. 218° , is largely

the picrate of II; their nitrate is its pure dinitrate. Z. and B.'s conclusions are based on repeated analyses of the picrate and nitrate, the absence of HCHO-titratable and van Slyke N and the synthesis of II from d-arginine and $\text{H}_2\text{NC}(\text{NH.HBr})\text{SET}$; this gives first an optically active dinitrate of II which, after its very ready racemization, is completely identical with F.'s salt. Z. and B. explain the formation of II as follows: as soon as the arginine ester is liberated from its HCl salt, the guanido residue of 1 mol. reacts with a 2nd ester mol. to form a peptide of the hitherto unknown type $\text{H}_2\text{NC}(\text{NH})\text{NHCH}_2\text{CH}_2\text{CH}_2\text{CH}(\text{NH}_2)\text{CONH.C}(\text{NH})\text{NHCH}_2\text{CH}_2\text{CH}(\text{NH}_2)\text{CO}_2\text{Me}$, with the peptide union on the guanido group. This, however, cannot be isolated and rapidly undergoes further change; the peptide-guanido group combines with the adjacent NH_2 group, with ring closure (formation of II) and splitting off of Me ornithine or some closely related deriv. As a matter of fact, the mother liquors from F.'s picrate give on benzoylation after removal of the picric acid more than 30% of d-ornithuric acid. The HCHO-titratable and van Slyke N found by Kossel and Staudt and by Edlbacher and Bonem must have been due to their using the 218° picrate, which is certainly not homogeneous; after purification through the nitrate it m. 10° higher. The same is probably true of the supposed hydrolysis of I, with formation of urea, by arginase. The dinitrate, as stated above, is optically active, but the free II autoracemizes with extraordinary rapidity as soon as it is liberated with the equiv. quantity of alkali (1.5 hrs. in dil. aq. soln. at 20°). The same phenomenon has been observed with d-phenylalanyl-d-arginine anhydride (unpublished investigation). In both cases the CO of the CO_2H group and the asym. C atom with its N form part of a ring and are under the influence of a guanido group. The formation of a ring by the center of asymmetry seems to be a prerequisite of the autoracemization which is initiated by the basicity of the guanido group and carried to completion with extraordinary rapidity. d-Dinitrate of II, m. 189° (cor.), $[\alpha]_D^{19} -28.6^\circ$ (H_2O); d-picrate, unlike the dl-salt, seps. in well-de-

veloped long yellow leaflets or rodlets, m. 228° (cor.). The mother liquors of the picrate with BzCl gave, in addn. to ornithuric acid, about 10% of dibenzoyl-*d*-arginine, m. 244°, $[\alpha]_D^{20}$ 10.12° (0.2 *N* NaOH), whereas Gulewitsch gives 217–7.5° as the m. p. When 5 g. *d*-arginine in 100 cc. H₂O was benzoylated in the usual way with 30 cc. BzCl and 55 cc. of 33% NaOH, pptd. with HCl, freed of BzOH with Et₂O-petroleum ether and crystd. from hot H₂O the product m. 218° but still contained much HCl which could be more or less completely removed only by repeated crystn. from H₂O; this was more conveniently effected by cautiously adding NH₄OH to an aq. soln. as long as a ppt. formed. The product then m. 244° (cor.) and formed long prisms with 1.5 H₂O; from 50°C. alc. it sepd. in long slender needles with 1 H₂O. C. A. R.

Continued studies on the behavior of polypeptides and their derivatives toward dilute alkali and dilute acid. VII. Further experiments with polypeptides substituted in the amino group. EMIL ABDERHALDEN AND PAUL MÖLLER. *Z. physiol. Chem.* 176, 207–16(1928); cf. C. A. 22, 1757.—New derivs. prepd. for detg. the influence of substituent groups on the alkali cleavage of leucylglycine are: *β*-naphthoyl-*dl*-leucylglycine (I), m. 193–4° (yield, 79%); benzylsulfonyl-*dl*-leucylglycine (II), m. 90° (yield, 61.5%); *p*-toluenesulfonyl-*dl*-leucylglycine (III), m. 120° (yield, 71.5%); phenylacetyl-*dl*-leucylglycine (IV), m. 170° (yield, 61%); *β*-phenylpropionyl-*dl*-leucylglycine (V), m. 187° (yield, 43%). The hydrolysis test was performed in each case with *N* NaOH at 37°. The cleavage invariably yielded glycine and the substituted leucine; in no case was the substituent group split off from the leucine. It was previously found that Bz accelerates and PhSO₂ retards the cleavage of leucylglycine. Similar results are now reported for analogous substituents. I undergoes cleavage more rapidly than the unsubstituted dipeptide but less rapidly than the Bz deriv. II and III are not attacked by *N* alkali at 37°. IV, which corresponds to II except that the linkage occurs through C instead of S, is hydrolyzed as rapidly as the Bz deriv. Lengthening of the substituent chain, as in V, decreases only slightly the cleavage velocity. In general, the derivs. of leucylglycine in which the N of the free NH₂ is linked to the C of a substituent group are hydrolyzed at a lower OH-ion concn. than the unsubstituted dipeptide. The PhNCO and α -C₁₀H₇NCO derivs. of leucylglycine are the most sensitive to alkali of any thus far examd. The *p*_H limit here is about 11.7, and at *p*_H 13 (0.1 *N* NaOH) complete hydrolysis occurred in 1.5 days. It is possible that other substituents, e. g. an enzyme complex such as erepsin, render the dipeptide sensitive to a still lower OH-ion concn. Perhaps erepsin functions in this manner. A. W. DOX

The conversion of dimethylisobutyrylcarbinol into methylisopropylacetylcarbinol. MILE. A. I. OUMNOFF (previously UMNOWA). *Bull. soc. chim.* 43, 568–71(1928); cf. *J. prakt. Chem.* 88, 646, 679(1913).—Boiling 2-chloro-2,4-dimethylpentan-3-one with aq. K₂CO₃ gives a HO ketone (I), b. 164° (semicarbazone, m. 195–6°), differing from the HO ketone (II), b. 161–2°, d_4^{20} 0.9301, d_4^{20} 0.9132 (semicarbazone, m. 178–9°), obtained from the corresponding *Br* ketone. II was converted by treatment with PhMgBr into a glycol, C₁₃H₂₆O₂ (III), m. 75–6°, which was then oxidized by CrO₃ and NaHSO₄, giving acetone and *Ph iso-Pr* ketone, b_{7H} 221–1.5° (semicarbazone, m. 167–7.5°). III, therefore, was 2,4-dimethyl-3-phenylpentane-2,3-diol and II was dimethylisobutyrylcarbinol, the oxidation of III causing a break between C atoms 2 and 3. By treating I in the same manner a glycol (IV), b₁₄ 153–5°, was obtained which oxidized to give PhCOMe. IV was, therefore, 2-phenyl-3,4-dimethylpentane-2,3-diol and I was methylisopropylacetylcarbinol, the oxidation of IV causing a break between C atoms 2 and 3. I was also obtained by heating 7.5 g. of II at 120° for 8 hrs. in a sealed tube with 20 g. of EtOH and 3 drops of concd. H₂SO₄. This rearrangement probably takes place through the oxide alc. form Me₂CHC(OH).O.CMe₂. A. S. CARTER

The conversion of oxoctanol into methyl-*tert*-butylacetylcarbinol. MILE. A. I. OUMNOFF (previously UMNOWA). *Bull. soc. chim.* 43, 571–3(1928).—Oxoctanol (6.6 g.), Me₂C(O).C(OH)CMe₃, b. 178–8.5°, m. 49.5°, was heated in 50 g. of EtOH with

2 drops of concd. H₂SO₄ for 8 hrs. at 120°. The product was poured into satd. aq. K₂CO₃ and extd. with Et₂O. Evapn. gave a HO ketone (I), b₁₄ 176–8°, d_4^{20} 0.9505, d_4^{20} 0.9362, M.R. 40.20; semicarbazone, m. 190–90.5°. 2.7 g. of I was oxidized by 1.2 g. of CrO₃ and 4.9 g. of KHSO₄ in 12 g. H₂O, steam-distd. and neutralized with K₂CO₃. The neutral product was distd. off and identified as *pinacolin* (II). The acids were pptd. as Ag salts and suggested a mixt. of HOAc and Me₃CCO₂H. The oxidation products proved I to be methyl-*tert*-butylacetylcarbinol, oxidation splitting off the Ac group to leave II. A. S. CARTER

Synthesis of heptane-1,5-dicarboxylic acid. ALBERT S. CARTER. Univ. Wisconsin. *J. Am. Chem. Soc.* **50**, 1967-70(1928).—*Di-Et γ -phenoxypropylmalonate*, b_{20} 228-35°, results in 76% yield from $\text{CH}_2(\text{CO}_2\text{Et})_2$, $\text{PhO}(\text{CH}_2)_3\text{Br}$ and Na; the free acid m. 72-8° (90% yield); heating at 175° gives 90% of $\text{PhO}(\text{CH}_2)_3\text{CO}_2\text{H}$, m. 55-6°; HI gives 68% of $\text{I}(\text{CH}_2)_3\text{CO}_2\text{H}$, whose *Et ester* b_{20} 108-18°; with $\text{EtCH}(\text{CO}_2\text{Et})_2$ and Na this gives the *tri-Et ester*, b_{20} 192-200°, of *heptane-1,5,5-tricarboxylic acid*, m. 88-8°, decomps. 140°, giving heptane-1,5-dicarboxylic acid, m. 41.5-3°, analyzed as the Ag salt. C. J. WEST

Determinations of the viscosity and of the melting point in the oxalic acid series. The alternating properties of homologous series. R. CEDER. *Ann. Univ. Fennicae Aboensis Series A2*, No. 4, 14 pp.(1926); *Chem. Zentr.* **1927**, I, 2398.—The viscosities and f. ps. of the di-Me and di-Et esters of the oxalic acid series from oxalic to sebacic acid were measured. The substances were first purified by distn. *in vacuo*. The following data give the f. p. (cor.) and the viscosity (η) at 20°, resp., of each compd. studied: *di-Me esters*—malonate, -59.6°, 0.02213; succinate, 20°, 0.02816; glutarate, -37.4°, 0.02711; adipate, 8.5°, 0.03292; pimelate, -20.6°, 0.03666; suberate, -3.1°, 0.04181; azelate, -3.9°, 0.04996; *di-Et esters*—oxalate, -41.7°, 0.01979; malonate, -51.4°, 0.02135; succinate, -21.8°, 0.02755; glutarate, -24.1°, 0.02862; adipate, -21.4°, 0.03568; pimelate, -23.8°, 0.04024; suberate, 5.9°, 0.04453; azelate, -18.5°, 0.05203; sebacate, above 51°, 0.06097. From these data can be calcd. the increments of viscosity from each di-Me ester and from each di-Et ester to the next. The magnitudes of these differences show an alternating effect. The introduction of a CH_2 group increases the viscosity, though di-Me glutarate is an exception, as a result of which the difference between di-Me glutarate and di-Me succinate is negative. The f. ps. also show noteworthy increases and decreases. Di-Me malonate was even at -84° a turbid, sirupy mass which at -59.6° (cor.) again became a transparent, clear liquid. At -73° di-Et malonate was a thick mass, which at -51.4° (cor.) again became a light liquid. Perhaps both esters form liquid crystals. C. C. DAVIS

Ethyl aminomalonate. R. LOCQUIN AND V. CERCHEZ. *Compt. rend.* **186**, 1360-2 (1928).— $\text{NH}_2\text{CH}(\text{CO}_2\text{Et})_2$ (I) is obtained in a 65% yield by reduction of $\text{HON}:\text{C}(\text{CO}_2\text{Et})_2$ (II) with Al-Hg. II, b_{12} 166°, is obtained in a 90% yield by dropping a satd. NaNO_2 soln. (3 mols.) into 1 mol. of $\text{H}_2\text{C}(\text{CO}_2\text{Et})_2$ in 3 mols. Ac_2O under const. stirring. I, b_{12} 116-8°, is easily sol. in H_2O and ordinary org. solvents, absorbs CO_2 from the air, and gives the following characteristic derivs.: $\text{NH}_2\text{CH}(\text{CO}_2\text{Et})_2\cdot\text{H}_2\cdot\text{C}_2\text{O}_4$, m. 138°, sol. in H_2O , alc., insol. in Et_2O , ligroin; $\text{NH}_2\text{CONHCH}(\text{CO}_2\text{Et})_2$, m. 167°; $\text{NH}_2\text{CH}(\text{CONH}_2)_2$, m. 196°; $\text{PhCONHCH}(\text{CO}_2\text{Et})_2$, m. 61°. I has a H atom which can be replaced by Na, making thus many syntheses possible; the alkyl derivs. are obtained from the Na deriv. in a 50% yield. When the alkyl derivs. are sapon. with superheated H_2O , they lose a CO_2 , yielding thus directly an α -amino acid $\text{RCH}(\text{NH}_2)\text{CO}_2\text{H}$; leucine and phenylalanine have been prepd. by this method. Contrary to the expectations, the acid chlorides link their radical on the N instead of the C bearing Na. The acylated derivs. thus obtained are incapable of forming a Na deriv. A. L. H.

Synthesis of hydroxyamino acids (the conversion of glutamic acids into δ,δ -dialkyl- δ -hydroxy- γ -aminovaleric acid). S. KANAO AND S. INAGAWA. *J. Pharm. Soc. Japan* **48**, 355-8(1928).— *δ -Hydroxy- γ -aminovaleric acid* (I), which has not yet been described in literature, was obtained in good yield. Di-Et glutamate and organo-magnesium halide gave α' -(α -pyrrolidonyl)-dialkylcarbinol (II), which on sapon. gave I. Thus an α -aminocarboxylic acid was converted into hydroxyamino acid. The *Et deriv.* of II could be easily sapon. by $\text{Ba}(\text{OH})_2$, but for the *Bu* or *di-Ph* derivs., sapon. with EtOH-KOH was necessary. The following new compds. are described: *δ,δ -diethyl- δ -hydroxy- γ -aminovaleric acid*, softens at 70-80°, m. 143°, $[\alpha]_D^{20}$ 3.36° (H_2O), -14.48° (in 0.3 N HCl). *$\delta\delta$ -Dibutyl- δ -hydroxy- γ -aminovaleric acid*, m. 147°. *δ,δ -Diphenyl- δ -hydroxy- γ -aminovaleric acid*, m. 204-5°, $[\alpha]_D^{20}$ 48.5° (in 5 N AcOH). NAO UYRI

Alkylation of hydromolybdenocyanic acid. F. HÖLZL WITH G. I. XENAKIS. *Monatsh.* **48**, 689-709(1927).—When K molybdeno-octacyanide is treated with Me_2SO , there is formed the compd. $[(\text{CN})_4\text{Mo}(\text{CNMe})_2(\text{H}_2\text{O})_2]\cdot 4\text{H}_2\text{O}$ (I). Methylation of Ag molybdenocyanide with MeI affords a complex mixt. of compds. from which the substance $[(\text{CN})_4\text{Mo}(\text{CNMe})_4]\cdot 2\text{MeOH}$ (II) is obtained by extrn. with abs. MeOH. When I is treated with KCN K molybdenocyanide is regenerated, while the action of water on II is to furnish I. These reactions suggest that the octa[methylcarbamylamine]molybdenum ion, $[\text{Mo}(\text{CNMe})_6]^{+}$, is unstable, whereas the corresponding Fe^+ ion is stable (cf. C. A. **22**, 224). When II is treated with alkali the carbamylamine odor is developed, and with AgNO_3 a light yellow ppt. is formed which also gives the carbamylamine odor with

alkali. **II** in H_2O when kept for a long time does not give a ppt. with $AgNO_3$. Extn. of the residue after removal of **II** with water furnishes the compd. $[(CNMe)_4(CN)_2Mo(O)_2]_2$ (**III**), which decomps. in air, gives no ppt. with $AgNO_3$, but reduces NH_4AgNO_3 . Treatment of the residue after removal of **II** and **III** with dil. HCl and subsequent evapn. of the acid-sol. products in a vacuum gives a residue from which by extn. with warm $MeOH$ and water, substances **IV** and **V** were obtained together with an insol. residue (**VI**). Compd. **IV** titrates as a tribasic acid (NH_4 salt described), develops a carbylamine odor in H_2O , and decomps. on keeping into **V**. Its constitution is probably $[(CN)_4Mo(H_2O)[C(OH)NHMe]_3] \rightleftharpoons [(CN)_4Mo(H_2O)(CO'NHMe)_3]H_3$. The compd. **V** is a weak acid in H_2O and loses 1 mol. of water when dried over P_2O_5 . It is represented $[(CN)_3(OH)Mo(H_2O)(CO'NHMe)]H \rightleftharpoons [(CN)_3Mo(H_2O)_2CNMe]OH$. The insol. residue (**VI**) is formulated as $[(CN)_2(H_2O)CNMe.Mo(O)_2]_2$. Ethylation of Ag molybdenocyanide gives a corresponding series of complex compds. B. C. A.

Carbonic acid azides. CHARLES V. HART, Stanford Univ. *J. Am. Chem. Soc.* 50, 1922-30(1928).—The product previously known as NCN_3 (carbon pernitride) is really *dicyanodiazide* (**I**), for which a method of prepn. is given (cf. Darzens, *C. A.* 6, 2075); **I** m. 40.3° (D. gives $35.5-6^\circ$), begins to decomp. at 70° and explodes with extreme violence at 170° ; when impure, **I** is dangerously explosive. With H_2O **I** gives CO_2 , $2HN_3$, and H_2NCN , with $NaOH$ the same products are formed. Reduction of **I** with H_2S in $EtOH$ gives $NCNC(NH_2)_2$. **I**, suspended in Et_2O , gives with NH_3 *dicyanamidazide* (**II**), m. 151.2° (decompn.). Two tests for proving the presence of azide groups are (1) heating the substance with $NaOH$ soln. to form NaN_3 , and (2) the reduction of the azide group to the NH_2 group by means of H_2S with simultaneous evolution of N and the pptn. of S . Aminotetrazole- $HN(CN)_3$, suspended in H_2O and neutralized with $NaOH$, then treated with $CNBr$, gives pure **II**. **II-HCl**, crystg. with 1 H_2O , loses its cryst. appearance above 150° . $NCNC(NH_2)_2$ and $PhNH_2$ in $EtOH$ give *dicyanophenylamidazide*, decomps. above 145° ; the Na salt results on neutralizing the azide. Reduction gives $NCNC(NH_2)_2NHPh$. *Dicyano- α -naphthylamidazide*, decomps. slowly when heated, Na salt, $MeNH_2$, $EtNH_2$, and $PhNH_2$ also react but the products were not purified. $C_2N_4(N_2)_2$ is reduced by H_2S to $C_2N_2(NH_2)_2$, thus eliminating the tetrazole structure. With NH_3 there results *cyanouramidodiazide*, starts to decomp. at 200° and decomps. with great violence when heated suddenly at 210° ; reduction gives $C_2N_2(NH_2)_2$. Cyanuric trichloride and NaN_3 give *cyanuric dichloride azide*, m. 85° . C. J. WEST

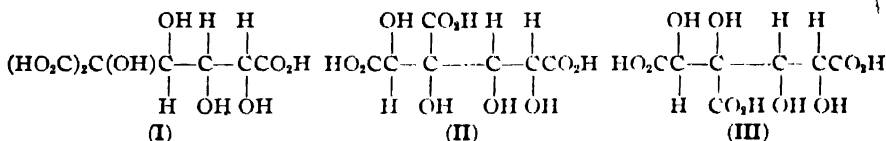

The preparation of *d*-arginine monohydrochloride. GERALD J. COX, *J. Biol. Chem.* 78, 475-9(1928).—A stable, pure final product is obtained from gelatin by the use of a modification of the flavianic acid method of Kossel and Gross (*C. A.* 18, 1681). Hydrolysis of the protein and decompn. of the arginine flavianate are accomplished by the use of HCl . Arginine- HCl is obtained as the final product and can be efficiently purified by pptn. with alc. from concd. aq. solns. In the prepn. of arginine- HCl from solns. contg. an excess of HCl , use was made of the convenient basicity of aniline and the soly. of aniline- HCl in alc. Arginine *disflavianate*, $C_{20}H_{24}N_8S_2O_{10}$, was prepd. and its identity confirmed by combustion analysis. It m. 170.5° (decompn.) when heated rapidly. Conversion to the monoflavianate by treatment with an excess of arginine- HCl gave 97.8% of the calcd. quantity. Arginine- HCl is assigned the formula $C_6H_{14}N_4O_2.HCl$, which corresponds to the analysis. The substance has no water of crystn., contrary to findings of some other investigators. The m. p. is 222° . No loss in wt. occurred on heating at 110° for 12 hrs. C. R. FELLERS

New derivatives of barbituric acid. ARTHUR W. DOX and EDWARD G. JONES, Parke, Davis and Co. *J. Am. Chem. Soc.* 50, 2033-6(1928).—*Tetrahydrofuranmethyl bromide*, b_{14} $168-70^\circ$, from the alc. and HBr or PBr_3 in 25% yields; *Et ethyltetrahydrofuranmethylmalonate*, b_{14} $155-7^\circ$; condensation with $CO(NH_2)_2$ gives 75% of *ethyltetrahydrofuranmethylbarbituric acid*, m. 190° . *Et amylmalonate*, b_{14} $134-6^\circ$ (62% yield); *amylmalonamide*, m. 206° , from the ester and concd. NH_4OH ; in $AcOH$, Cl gives *amylchloromalonamide*, m. 134.5° , has an intense sweet taste (a 0.005% aq. soln. showed the same degree of sweetness as a 2% sucrose soln.). *Amylbarbituric acid*, m. 215° . *Et diamylmalonate*, b_{11} $158-61^\circ$; *diamylbarbituric acid*, m. 118° . *Et amylethylmalonate*, b_{14} $139-41^\circ$; *amylethylbarbituric acid*, m. 135° ; this is an effective hypnotic with several times the potency of barbital. C. J. WEST

New (observations) in the chemistry of the sugars. VIII. H. KILIANI, Univ. Freiburg i. B. *Ber.* 61B, 1155-69(1928); cf. *C. A.* 20, 2985.—*I. Liability of l-mannosaccharic acid.*—When K. stated that the double lactone of this acid differs most surprisingly from all other analogously constituted substances of the sugar group in its behavior towards alkalis and Fehling soln. he was unaware that Peirce (*C. A.* 10, 1845)

describes the dilactone of his "*d*- α -mannooctaric acid" as also "powerfully" reducing Fehling soln. although Winger expressly states that the optically inactive " α -galactooctanehexol diacid," obtained from *l*-mannohepturonic acid with HCN, which is doubtless identical with P.'s acid, does not react with Fehling soln. On repeating the test both with W.'s original prepn. and with a new sample prepd. by K. himself, K. has been able to observe no trace of reduction when the dilactone is previously dissolved in KOH. P.'s finding may have been due to the fact that he used the solid free dilactone in large quantities or, since he prepd. his acid by HNO_3 oxidation, that his compd. was contaminated with aldehyde or ketonic acids. Since the mannosaccharic acids show such a peculiar high sensitivity to alkalis and alk. Cu solns. it must be concluded that at the instant when they so react they undergo an intramol. rearrangement with formation of an aldehyde or ketone radical. The possibility of aldehyde formation may be excluded, since it would involve an end CO_2H group; there thus remains only the possibility of ketonization which may provisionally be represented by the scheme $\text{RR}'\text{CHOH} \rightarrow \text{RR}'\text{CO} + 2\text{H}$. Representing the four C atoms between the 2 CO_2H groups in mannosaccharic acid by α , β , β' , and α' , then, if the ketonization occurs at the α - or α' -C atom this C atom will lose its asymmetry when the product is treated with KCN and hydrolyzed and there should result a single tri- CO_2H (I) acid, the mirror image of the acid obtained by Dull by oxidation of "levulosecarboxylic acid." On the other hand, if the ketonization occurs at the β -C atom, treatment with KCN and hydrolysis should give 2 tri- CO_2H acids (II and III). Expt. showed that a tri- CO_2H acid (IV) is actually formed and that it differs materially in its properties from D.'s compd. The fate of the H liberated in the ketonization remains uncertain. There is not the slightest indication of an evolution of H_2 during the reaction and no MeNH_2 , which might have been formed according to a reaction $\text{KCN} + 4\text{H} + \text{H}_2\text{O} = \text{MeNH}_2 + \text{KOH}$, analogous to osazone formation, could be detected. A search will therefore have to be made for a reduction product of mannosaccharic acid as to whose nature it is difficult to make any predictions. x g. of the mannosaccharic dilactone in 9.5x g. H_2O is treated in the course of 20–30 min. with 9.5x cc. *N* KOH, then, after 7.5 hrs., with 2 mols. com. (90%) KCN, allowed to stand 7–8 days at room temp., heated 5–6 hrs. in an open flask on a water bath, evapd. to 3x g., dild. with 2x cc. H_2O , slowly treated with a quantity of 50% AcOH equiv. to the total K present, allowed to stand 2 hrs. with occasional stirring under a hood, pptd. with 1:1 CaCl_2 ($\text{C}_6\text{H}_{10}\text{O}_6 \cdot 2\text{H}_2\text{O} : 1.5\text{CaCl}_2$), filtered after 12 hrs. and washed free from Cl with 20% alc. (The alc. washings ppt. from the filtrate a voluminous but relatively light Ca salt, possibly of a reduction product of the mannosaccharic acid.) The 1st Ca ppt., which contains about 10% of the salt of *l*-mannosaccharic acid, is dissolved in the calcd. quantity (calcd. by detg. the Ca in a portion of the ppt.) of cold 2 *N* HCl, treated with 75% of the calcd. quantity of cold satd. NaOAc, filtered after 24–36 hrs., washed with 20% alc., freed from Ca with $(\text{CO}_2\text{H})_2$, concd. at 35° to a thin sirup and drained from the mannosaccharic dilactone which crystallizes out. The filtrate (IV) does not reduce Fehling soln. and thus far has been obtained only as a thick sirup but its compn. is established by that of the Ca salt, $(\text{C}_7\text{H}_7\text{O}_{10})_2\text{Ca}_3 \cdot 9\text{H}_2\text{O}$, and basic Cu salt, $(\text{C}_7\text{H}_7\text{O}_{10})_2\text{Cu}_3 \cdot \text{Cu}(\text{OH})_2 \cdot 18\text{H}_2\text{O}$, light blue microcolumns. $[\alpha]_D$ for IV (calcd. from the rotation of the Ca salt in HCl) is -22.8° . II. *Prepn. of l-mannosaccharic acid, "levulosecarboxylic acid" and Dull's tribasic acid.*—In prepg. the *l*-mannosaccharic dilactone by his new method with concd. HNO_3 at room temp. K. regularly obtained yields materially smaller than in his earlier work (52.8%) because, as he finally discovered, his later work was done in winter and the temp. fell considerably at nights. The dilactone can be readily obtained in 52–5% yield by heating x g. (not more than 20 g. in 1 operation) 22–4 hrs. at 50° with 2x cc. HNO_3 (d. 1.2), concg. at 50° to 2x g., seeding, letting stand 2 hrs. in ice, draining off the crystals (30%), washing with the least possible quantity of H_2O , concg. the filtrate to 1.2x g., and freeing the filtrate from the 2nd crop (16–8%) of HNO_3 with Et_2O , whereupon a 3rd crop can readily be obtained. Levulosecarboxylic lactone, $[\alpha]_D$ 72.9° (H_2O), was prepd. by treating crystd. levulose in an equal wt. of H_2O with 1.2 times the calcd. quantity of 20–30% HCN, then, after 10 min. in ice, with a little NH_4OH , allowing to stand 24 hrs. in ice and 4–5 days at room temp., satg. in the cold with HCl, removing the excess of HCl after 24 hrs. by distn. *in vacuo*, the NH_3 with $\text{Ba}(\text{OH})_2$, the Ba with H_2SO_4 and the Cl with Ag_2CO_3 , and converting the acid through the brucine and Ba salts into the lactone. This (x g.) with 3x cc. HNO_3 (d. 1.2) 20 hrs. at 45° and 8–9 hrs. at 65°, gives Dull's $\alpha, \beta, \gamma, \delta$ -tetrahydroxybutane- α, α, δ -tricarboxylic acid; Cu salt, $(\text{C}_7\text{H}_7\text{O}_{10})_2\text{Cu}_3 \cdot 2\text{H}_2\text{O}$, very light blue microtables; the air-dry tri-K salt contains 3 mols. H_2O . III. *Use of oxalic (instead of sulfuric) acid for the detn. and pptn. of Ba in salts of org. acids.*— BaSO_4 forms with the Ba salts of the poly-HO acids of the sugar

group colloidal mixts. which introduce considerable difficulties into the working up of large quantities of these salts for the free sugar derivs. These can be obviated by detg. the Ba content in a portion of the soln. and using exactly the calcd. quantity of $(\text{CO}_2\text{H})_2$ instead of H_2SO_4 . For the detn. of Ba, about 2 times the calcd. quantity of $(\text{CO}_2\text{H})_2$ (1.12) is added, then enough 95% alc. to make the final mixt. about 50% EtOH, and the ppt is dried on the filter paper at 100° . The cryst. ppt. carries down and holds tenaciously considerable quantities of any humin-like substances present; in such cases a portion of the dried ppt. is converted into the carbonate by gentle ignition. To remove Ba, no alc. is added and the ppt. is filtered off only 12 hrs. after adding the $(\text{CO}_2\text{H})_2$.

C. A. R.

Relations between rotatory power and structure in the sugar group. XVIII. α -Methyl-*d*-lyxoside triacetate. F. P. PHELPS AND C. S. HUDSON. *Int. Standards. J. Am. Chem. Soc.* 50, 2049-51 (1928); cf. *C. A.* 20, 3159— *α -Methyl-*d*-lyxoside triacetate*, m. 96° , $[\alpha]_{\text{D}}^{20}$ 30.1°, $[\alpha]_{\text{D}}^{25}$ 31.7°, $[\alpha]_{\text{D}}^{26}$ 35.8°, $[\alpha]_{\text{D}}^{27}$ 62.0°; from a comparison of these values with the rotation of α -methyl-*d*-lyxoside, it is concluded that the lyxoside deriv possesses a 1,4-ring structure and that cryst. α -lyxose ($[\alpha]_{\text{D}} 5.5^\circ$) also has this ring structure, since its rotation differs normally from that of α -methyl *d* lyxoside.

C. J. WEST

The synthesis of cane sugar. C. S. GIBSON. *Chemistry and Industry* 47, 355-6 (1928).—An historical discussion, concluding with a description of the work of Pictet and Vogel (*C. A.* 22, 2743).

T. S. CARSWELL

Mechanism of carbohydrate oxidation. IX. The action of copper acetate solutions on glucose, fructose and galactose. W. L. EVANS, W. D. NICOLI, G. C. STROUSE AND C. E. WARING. Ohio State Univ. *J. Am. Chem. Soc.* 50, 2267-84 (1928); cf. *C. A.* 22, 2146.—Aq. solns. of fructose, glucose and galactose have been oxidized with $\text{Cu}(\text{OAc})_2$ at 50° for the purpose of ascertaining whether the general principles underlying the mechanism of carbohydrate oxidation in alk. solns. are sufficient to explain the course of such oxidations in acid soln. The advantages of the use of $\text{Cu}(\text{OAc})_2$ are outlined. The reaction mixts. were examd. for glucosone, HCO_2H , CO_2 , $(\text{CO}_2\text{H})_2$ and $\text{HOCH}_2\text{CO}_2\text{H}$. The presence of $\text{HOCH}_2\text{CO}_2\text{H}$ was proved qual. but it was not measured quant. The quantities of these are expressed both as functions of the time and the O consumed. The O consumed by each sugar is expressed as a function of the time. The H-ion concn. is expressed as a function of the O consumed. The hexose-1,2-enediols are regarded as being oxidized to the hexosones. The glucosone is obtained as the osazone. The galactosone was not obtained as a reaction product. It is probably used up as rapidly as it forms. The HCO_2H arises from the oxidation of the hydroxymethylene obtained by the decompn. of the hexose-1,2-enediols. That hydroxymethylene will undergo this change was shown by a study of the behavior of $\text{Cu}(\text{OAc})_2$ towards HOCH_2CHO and $\text{HOCH}_2\text{COCO}_2\text{H}$. It is thought that CO_2 arises from the decompn. of the unstable α -ketohexonic acids. $\text{HOCH}_2\text{COCO}_2\text{H}$ loses a mol. of CO_2 when oxidized with $\text{Cu}(\text{OAc})_2$. The hexosones may form hexosone-1,2-enediols, which are thought to decomp. into the active form of the tetrose (tetrose methylenol) and glyoxal (half active form). The latter is oxidized to $(\text{HO})_2\text{CHCO}_2\text{H}$, which in part is converted into $(\text{CO}_2\text{H})_2$ and $\text{HOCH}_2\text{CO}_2\text{H}$. $(\text{CHO})_2$ does not reduce $\text{Cu}(\text{OAc})_2$ solns.; hence it is thought that the $\text{HOCH}_2\text{CO}_2\text{H}$ comes from an activated form (glyoxal-half-methylenol). The increase in the H-ion concn. tends to reverse the equil. between the enediols in the direction of suppressing enediol formation. This would lead to a reduction in the HCO_2H yields with increasing time. The increase in the H-ion concn. would tend to suppress the enolization of the hexosone-2,3-enediol. This harmonizes with the fact that no derivs. were found of 2,3-diketohexones when the reaction mixts. were treated with PhNHNH_2 . The view is expressed that aldehydes exist in 2 forms, those active towards oxidizing agents and those not. The former are derivs. of methylenols; that is, the H is bound to O and the C is bivalent. In the inactive mols. the C is quadrivalent. An equil. exists between these 2 forms, which may be shifted by a change in the H-ion concn. The conversion of aldehydes to carbonates in alk. solns. is explained on this basis.

C. J. WEST

Acetone compounds of sugars and their transformation products. IX. Transfor-

mation of monoacetoneglucose. HEINZ OHLE and LADISLAUS VON VARGHA. Univ. Berlin. *Ber.* 61B, 1203-8(1928); cf. *C. A.* 21, 1968-9.—The *p*-toluenesulfomonoacetoneglucose m. 108° (I) obtained from monoacetoneglucose and 1 equiv. *p*-MeC₆H₄SO₃Cl splits off MeC₆H₄SO₃H with NH₃ in MeOH with surprising ease even in the cold, giving a small quantity of a N-free, Et₃O-sol. product which it has as yet not been possible to cryst., and, chiefly, a H₂O-sol., Et₃O-insol. aminomonoacetoneglucose *p*-toluenesulfonate (II) contaminated with MeC₆H₄SO₃NH₄. The free base (III) could not be obtained in cryst. form; it is strongly basic and easily combines with CO₂; II with Na₂CO₃ gives a well-crystd. substance (IV) which, from its N content, is not, to be sure, the carbonate but a carbamate, RCH₂NHCO₂ H.NH₂R, probably formed from the carbonate by loss of H₂O in the concn. of the aq. soln. In H₂O IV shows mutarotation, presumably because of the reverse transformation into the carbonate. II can readily be purified through this IV. With dil. acids IV gives 6-aminoglucose (V), identical with Fischer and Zach's product. V and its carbonate and toluenesulfonate are amorphous and its picrate, although isolated in deep yellow needles, had no sharp m. p.; the phenylhydrazone *p*-toluenesulfonate (VI), however, faintly yellow needles, m. 182-3° sharply. The NH₂ group in III must, therefore, be in position 6, and as III with HNO₂ gives the known monoacetoneglucose, it must have the same ring structure as the latter. Therefore, I must also contain a 1,4-O bridge (unless the very improbable assumption is made that it contains a 1,6-bridge) and since the 3-MeC₆H₄SO₃ deriv. is known, I can be only the 6- or the 5-deriv. IV, C₁₂H₁₄O₁₂N₂, m. 80° (gas evolution) on rapid heating, decomp. 180-90° on slow heating, $[\alpha]_D^{20}$ 0° (initial), -6.25° after 2 days (H₂O, c 4.002). II, m. 176-7° (decompn.), $[\alpha]_D^{20}$ -7.02° (H₂O, c 5.010). Carbonate of V, m. 96-8° (CO₂ evolution), $[\alpha]_D^{20}$ 12.5° (H₂O, c 2.077); *p*-toluenesulfonate, very hygroscopic, $[\alpha]_D^{20}$ 31.68° (H₂O, c 1.128); picrate, begins to decomp. 140°, m. 160°, $[\alpha]_D^{20}$ 7.4° (H₂O, c 2.036); VI, $[\alpha]_D^{20}$ 6.8° (initial), 1.3° after 16 hrs. (alc., c 2.514). X. A new *p*-toluenesulfodiace-toneglucose. *Ibid* 1208-10.—The observation of O. and Dickhäuser that I reacts with Me₂CO in the presence of anhyd. CuSO₄ was due to the fact that their material was impure. When the I is crystd. from PhMe, which is a wasteful method but gives a pure product directly, it cannot be acetonated with CuSO₄. With small quantities of mineral acids (best H₂SO₄) as catalyst, however, acetonation can be effected, but the resulting *p*-toluenesulfodiace-tone-d-glucose (VIII) is different from Freudenberg and Ivers' 3-*p*-toluenesulfodiace-tone-d-glucose- $\langle 1,4 \rangle$ (VIII). If I is the 6-MeC₆H₄SO₃ deriv., the formation of an isomer of VIII under the influence of acids can be explained by assuming that the 1,4-bridge in I is changed to a 1,3-bridge, leaving 2 adjacent HO groups on C atoms 4 and 5 with which the Me₂CO can react without the MeC₆H₄SO₃ group having to migrate. These results are of importance in connection with the reaction of I with HBr-AcOH, which, as O. and Spenger found, gives a product isolated as a toluenesulfotriacetyl- β -methylglucoside (IX), m. 155°. IX at the time was assumed to be 6-toluenesulfo-2,3,4-triacetyl- β -methylglucoside- $\langle 1,5 \rangle$, but this compd. has since been synthesized by Helferich, Brederick and Schneidmüller and found to be different from IX. Alk. sapon. of IX has hitherto given only sirupy products and VIII treated with HBr-AcOH and then MeOH and Ag₂CO₃ does not give IX but a small quantity of a cryst. substance m. 120° contg. S and reducing Fehling soln. only after hydrolysis with mineral acids. Apparently, therefore, VIII and IX do not have analogous structures. VIII (70-5% from 10 g. I in 200 cc. Me₂CO shaken 2 days with 20 g. anhyd. CuSO₄ and 0.5 cc. concd. H₂SO₄), m. 87°, $[\alpha]_D^{20}$ 27.1° (CHCl₃, c 5.244), does not react with Fehling soln., AgNO₃-NH₃ or PhNHNH₂. XI. Transformation of monoacetone-d-glucose into 3,6-anhydro-d-glucose. HEINZ OHLE, LADISLAUS VON VARGHA and HEINZ ERLBACH. *Ibid* 1211-6.—The striking behavior on hydrolysis with aq. alc. acids of the di-*p*-toluenesulfomonoacetone-d-glucose (X) obtained by O. and Dickhäuser from monoacetoneglucose and 2 mols. MeC₆H₄SO₃Cl, which they assumed to be a 5,6-di-MeC₆H₄SO₃ deriv., led the authors to make a more thorough study of its structure. On alk. hydrolysis, if the quantity of alkali is limited to 1 mol. or the boiling with an excess of alkali is continued only a short time there is obtained a compd. (XI), m. 132°, already obtained by O. and D. in small yield from monoacetoneglucose and 3 mols. MeC₆H₄SO₃Cl in C₂H₅N at 100°; they believed it to be a 3rd toluenesulfomonoacetoneglucose. More careful analyses have shown, however, that it contains 1 mol. of H₂O less and is, therefore, a toluenesulfomonoacetoneanhydroglucose. Alk. hydrolysis gives a well-crystd. monoacetoneanhydroglucose (XII), which regenerates XI with MeC₆H₄SO₃Cl in C₂H₅N and splits off the Me₂CO residue with mineral acids, giving the same anhydro-d-glucose (XIII) as Fischer and Zach obtained from aceto-

dibromoglucose. The above results confirm the 3,6-anhydro structure assigned by F. and Z. to **XIII**. That 1 end of the O bridge is on C atom 6 was established by them by their prepn. of **XIII** from acetodibromoglucose. The other end cannot be on C atoms 2, 4 or 5 for in **XII** the HO groups on these C atoms are closed by the Me_2CO residue, the lactol ring and the $\text{MeC}_6\text{H}_4\text{SO}_2$ residue, resp. **XIII** can, therefore, have only the structure $\text{O}.\text{CH}_2.\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CHCH}(\text{OH})\text{CHO}$. This formulation in the alde-

hyde form has been chosen merely for the sake of simplicity. Although **XIII** is readily sol. in Me_2CO , it does not react with it and therefore probably exists in the form of a cyclohemiacetal or lactol; as to the length of the lactol O bridge, there are at present no certain indications. The above reactions show that the easily split off $\text{MeC}_6\text{H}_4\text{SO}_2$ group in **X** is in position 6 and the other cannot be in position 3, where the HO group must be free for the formation of the furan ring in **XIII**, leaving only position 5 for the 2nd $\text{MeC}_6\text{H}_4\text{SO}_2$ group, unless it be assumed that a change in the O bridge occurs in the formation of the **X**. With $\text{HBr}.\text{AcOH}$ **X** shows the characteristic play of colors through yellow and red to violet but no cryst. products could be isolated. **XI** should contain the same lactol ring but, as already pointed out by O. and Spenker, it does not give the color reaction with $\text{AcOH}.\text{HBr}$; an explanation for this, however, will be advanced in a forthcoming paper. Towards NH_3 in MeOH **X** behaves as towards alkalies, but under certain conditions a small quantity of an NH_3 compd. seems to be formed. **XI**, on the other hand, is not attacked even at 120° . Comparison of the behavior of **I** and **X** towards alkalies and NH_3 shows distinctly the influence of the 2nd $\text{MeC}_6\text{H}_4\text{SO}_2$ group. **XI**, $[\alpha]_D^{20}$ 39.3° (CHCl_3 , c 2.798). **XII**, m. $56-7^\circ$, $[\alpha]_D^{20}$ 29.33° (H_2O , c 3.172); *Bz deriv.*, m. $58-9^\circ$, $[\alpha]_D^{20}$ 22.28° (CHCl_3 , c 2.828); *Ac deriv.*, sirup, b_{0.05} $125-30^\circ$ (bath temp.), $[\alpha]_D^{20}$ 35.7° (CHCl_3 , c 4.920) C. A. R.

Oxidative synthesis of a dialdehydic carbohydrate, $\text{C}_{15}\text{H}_{22}\text{O}_{13}$, from dextrose. J. A. MANDEL AND J. B. NIEDERL. *XII Int Cong Physiol* 1926, 104 5. Oxidation of dextrose with $\text{Ba}(\text{OCl})_2$ yields an amorphous compd. of the compn. $\text{C}_{15}\text{H}_{22}\text{O}_{13}$, $[\alpha]_D$ 64° . Reduction affords a compd., $\text{C}_{15}\text{H}_{24}\text{O}_{13}$, $[\alpha]_D$ 98° (*Ac deriv.*, m. $112-4^\circ$). The bisosazone, $\text{C}_{30}\text{H}_{48}\text{O}_{11}\text{N}_8$, m. 194° . Oxidation yields mono- and di- $\text{CO}_2\text{H acids}$, $\text{C}_{14}\text{H}_{20}\text{O}_{14}\text{CO}_2\text{H}$ and $\text{C}_{13}\text{H}_{20}\text{O}_{13}(\text{CO}_2\text{H})_2$, resp. B. C. A.

Ring structure and optical relationships in the mannose-rhamnose-lyxose series of sugars. Isolation of a new form of lyxose. WALTER N. HAWORTH AND EDMUND L. HIRST. Univ. of Birmingham *J. Chem. Soc* 1928, 1221 30.—The first part of the theoretical discussion is polemical with Hudson (*C. A.* 20, 1981) regarding the optical relationships in the mannose-rhamnose-lyxose series. H. and H. suggest that the hypothesis of different ring structures in α - and β -mannoses affords little or no assistance in interpreting the exptl. observations; in the absence of definite chem. evidence to the contrary they consider it would be most helpful to the future study of the problem to regard α - and β -mannose as being not necessarily dissimilar in ring structure and to seek the reason for divergences in optical and other phys. properties occasioned by the special arrangement of HO groups in mannose and the related sugars rhamnose and lyxose. In their study of lyxose they have discovered a new cryst. variety. Lyxose was prepd. from Ca galactonate and isolated through the *p*-bromophenylhydrazine; β -lyxose, m. $117-8^\circ$; soly. in 90 and 85% EtOH at 18° , 0.8 and 1.7 g. per 100 cc., $[\alpha]_D^{20}$ -70° , equil. value 14° (H_2O , c 3.83); in EtOH , -80° and -9° . β -Lyxose remains unchanged after prolonged contact with 90% EtOH and the α -form has not been isolated from the soln. However, the β -form was converted into the known *p*-bromophenylhydrazine and osazone and α -Me lyxoside. C. J. WEST.

Alleged discovery of "caramelic acid." WALTER FUCHS. *Z. angew. Chem* 41, 85-8(1928).—The so-called caramelic acid which Marcusson claims to have isolated (cf. *C. A.* 22, 2126) both from humic acid and from dextrose by oxidation does not in fact exist. Material prepd. from humic acid, following exactly the directions given by Marcusson, is not a definite compd., does not give a Pb salt of const. Pb content, and proves in fact to be partly changed starting material. The product obtained from dextrose by following Marcusson's directions is entirely different from that obtained from humic acid. B. C. A.

Variation in rotation and conductivity of certain sugars in aqueous solution with and without boric acid. I. R. VERSCHUUR. *Rec. trav. chim.* 47, 123-52(1928).—According to Böeseken and Couvert (cf. *C. A.* 15, 2837), the rise in sp. rotation shown by certain sugars in the presence of H_3BO_3 is always accompanied by a marked increase in elec. cond. It is probable that there is a particular configuration of the terminal H atoms and HO groups which favors the formation of compds. with H_3BO_3 . Most

sugars, on soln. in water, undergo a transformation which can be followed with the polarimeter, and is due to the transition from the α - to the β -form, or the reverse, until equil. is attained. Such a change may involve an increase or a decrease in the power to combine with H_3BO_3 , and hence a corresponding change in cond. The behavior of α - and β -lactose in soln., in the presence and absence, resp., of H_3BO_3 , has been examd. The effect of H_3BO_3 on the rate of change of rotation of both forms is practically negligible. Although, from the structure of lactose, which resembles that of dextrose already examd. by Böeseken (*C. A.* 15, 2837), an increase in the equil. value of the cond. of the sugar soln., apart from that due to H_3BO_3 alone, might be expected, there is, on the contrary, a slight decrease. This suggests that the behavior of lactose is due to the galactose, and not to the dextrose portion of the mol. In addn., the equil. values for the 2 forms are not identical. The cond. of α -lactose alone, after soln., first increases and then decreases to the equil. point, but in the presence of H_3BO_3 there is a continuous decrease. The cond. of β -lactose alone remains const. at first and then decreases. In the presence of H_3BO_3 it increases continuously. In no case is the change unimol. The presence of a minute trace of impurity greatly affects the result. Expts. have been made at 12.9°, 15.5°, 20.0° and 25°. A few expts have been carried out with melibiose. In this case also there appears to be no increase in cond. in the presence of H_3BO_3 . Methods for the prepn. of pure α - and β -lactose are given. B. C. A.

Chemistry of lignin. II. Fractional extraction of lignin from corn cobs. MAX PHILLIPS. U. S. Dept. Agr. *J. Am. Chem. Soc.* 50, 1986-9(1928); cf. *C. A.* 21, 3056.—Lignin was fractionally extd. from corn cobs by a 2% EtOH-NaOH soln. at room temp., by 2% aq. NaOH at 100° and at 135° and finally by 4% aq. NaOH at 180°. Each method of extn. was continued until no further lignin was obtained, before the next method in the series was employed. The results justify the conclusion that the lignin in corn cobs is unequally combined with the carbohydrates, part of it being loosely bound, possibly in the form of an ester, and the remainder being more firmly held, probably in the form of an ether-like combination. C. J. WEST

Lignin. IV. Soluble pine lignin prepared by various methods. A. FRIEDRICH. *Z. physiol. Chem.* 176, 127-43(1928); cf. *C. A.* 21, 3203.—Further study of sol. pine lignin was undertaken to det. (1) the conditions under which the alc. method yields prepn. with max. alkoxy content, (2) the influence of the absence of H_2O during the prepn. of lignin, and (3) the stability of sol. lignin prepn. toward alkali. MeOH was used in place of EtOH in order to simplify the alkoxy detns., the extent of methylation which occurred being taken as the excess MeO over the 14.5% present in the original substance. From a series of expts. in which MeOH and HCl were used it appears that the absence of H_2O contributes only slightly toward increasing the MeO content of the prepn. On the other hand, the duration of the treatment with solvent is of greater significance. The same result is not obtained when the wood is boiled with MeOH-HCl and the dissolved lignin immediately pptd. as when the dissolved lignin is left in contact with the solvent for a longer period at room temp. The latter treatment, with 80% MeOH, yields a product with higher MeO content than the former with abs. MeOH. A combination of the 2 treatments, i. e. abs. MeOH and prolonged action, gave the max. MeO content of 23.2%. The other prepn. varied between 19.5 and 22.2% MeO. Treatment with alkali lowered the MeO content, but the quantity of Me thus removed varied with the different prepn. The greatest decrease was 4.5-5.0% from the prepn. with max. MeO content of 23.2%. On the assumption of a mol. wt. of about 650 for pure lignin, the addn. of 1 Me would raise the MeO content from 14.5 to 18.5%, and addn. of 2 Me would raise it to 22.8%. The prepn. with max. MeO represents, therefore, the addn. of 2 Me. On sapon. of this product the MeO dropped to 18.5%; hence 1 of the 2 Me groups introduced into the lignin mol. is in ester linkage. The 2 Me groups are evidently added simultaneously, since half of the added Me is split off by sapon. regardless of the MeO content of the prepn. The assumption of either an ester or an acetal linkage of lignin to cellulose is untenable. The taking up of alkyl groups is not a re-esterification, else it would occur immediately on rupture of the lignin-cellulose linkage. Actually, the addn. of alkyl is a secondary reaction between the lignin already dissolved and the solvent and reaches its max. only after 20 hrs. In attempting to prep. sol. lignin with only the MeO content of the original substance, 3 new methods of prepn. were developed, one of which, the AcOH method, is especially suitable by reason of simplicity and good yield and bids fair to supersede the usual EtOH method. If wood flour is added to AcOH contg. 3 vol. % concd. HCl and the mixt. warmed on a water bath, the lignin readily goes into soln. Within 0.5 hr. the liquid becomes yellow to brown; after 1 hr. it is deep brown or black. The wood residue is filtered off and the lignin pptd. from the filtrate by addn. of H_2O . The darker the soln. the greater is

the yield of lignin. However, it is advisable to interrupt the reaction as soon as a brown color has developed. Prepn. of lignin from dark brown or black solns. are discolored and resinify very rapidly to completely insol. products. To remove the adhering AcOH the product must be washed thoroughly with H_2O , then dissolved in EtOH and reprecip. by H_2O . The dried prep. then shows a MeO content of 10.5%, indicating that AcOH has been taken up. By warming the EtOH soln. with $N/45$ alkali and titrating back it is shown that 4 AcOH per mol. of lignin are present. The lignin thus treated now contains 14.4% MeO. Instead of the alkali treatment, reprecip. from $CHCl_3$ soln. by Et_2O may be used for removing this AcOH. The AcOH is merely "angelagert" and not in chem. combination. Purified lignin with a MeO content of 14.5% reacts with $PhNHNH_2$ to yield a product with 2.1% N and 13.5% MeO. This corresponds to 1 $PhNHNH_2$ per double mol. of lignin, and confirms F's previously stated view that the keto form of lignin is a double mol. Methylation of lignin with CH_3N_2 in EtOH or with Me_2SO_4 in alk. soln. raises the MeO to 23%, corresponding to the addn. of 2 Me. Sapon. then removes 1 Me. Titration of CO_2H in the sapon. product gives an equiv. of approx. 650, a value in agreement with the previously detd. mol. wt. of lignin. Benzoylation adds 3 Bz, and treatment with SO_2Cl_2 adds 3 Cl. Metallic salts of lignin were not obtained in sufficient purity for analysis because of the metallic hydroxide simultaneously occluded. Besides the AcOH method of prep. lignin, 2 other methods were used, involving the use of MeAc and $CHCl_3$. The last is the only one in which no reaction with the solvent occurs. The prep. of lignin by heating wood with alkali under pressure is believed to involve merely a change in the colloidal state of the lignin-cellulose aggregate and not a sapon. The same phenomenon of swelling occurs in the AcOH treatment. On the basis of analysis and mol. wt. detn. pine lignin has the empirical formula $C_{33}H_{36}O_{12}$. The mother liquor remaining after pptn from EtOH or $CHCl_3$ soln. by means of Et_2O or C_6H_6 contains various lignin substances which may be recovered by evap. the mother liquor, redissolving the residue and reprecip. Two such substances were thus obtained, one sol. in C_6H_6 and the other sol. in Et_2O . The wood residue also contains a small quantity of lignin which cannot be extd. by repeated treatments with AcOH.

Use of platinum-oxide platinum black in the catalytic reduction of aromatic hydrocarbons. XVII. ROGER ADAMS AND J. R. MARSHALL. Univ. of Illinois. *J. Am. Chem. Soc.* 50, 1970-3 (1928); cf. *C. A.* 21, 3053.—Pt oxide-Pt black is an excellent catalyst in the reduction with H of various types of aromatic hydrocarbons in glacial AcOH as a solvent. Results are given for C_6H_6 , PhMe, PhEt, m - $C_6H_4Me_2$, mixed $C_6H_4Me_2$, mesitylene, cymene, Ph_2CH_2 , Ph_3CH , α,α - $C_2H_5Ph_2$, $(PhCH_2)_2$, $PhCH_2CO_2H$ and $PhCH_2CH_2CO_2H$, the b. p., n_D and d. being given for each reduction product.

C. J. WEST

Cyclopropylmethylalkylacetic acids and their bactericidal action towards B. leprae. XIII. J. A. ARVIN AND ROGER ADAMS. Univ. Illinois. *J. Am. Chem. Soc.* 50, 1983-5 (1928); cf. *C. A.* 22, 2370.—*Di-Et cyclopropylmethylalkylmalonates*, $C_6H_5CH_2C(CO_2Et)_2R$, were prepd., where R is C_4H_9 , $b_{1,7}$ 122-5°, n_D^{20} 1.4459, d_4^{20} 0.9770 (this order will be used for n and d), C_6H_{11} , $b_{1,9}$ 130-42°, 1.4470, 0.9685; C_7H_{15} , $b_{1,7}$ 146-9°, 1.4481, 0.9613; C_8H_{17} , $b_{1,3}$ 149-54°, 1.4491, 0.9559; C_9H_{19} , $b_{1,3}$ 165-8°, 1.4503, 0.9512; $C_{10}H_{21}$, $b_{1,1}$ 162-6°, 1.4510, 0.9460; $C_{11}H_{23}$, b_1 186-9°, 1.4519, 0.9419; $C_{12}H_{25}$, b_2 183-7°, 1.4526, 0.9395; $C_{13}H_{27}$, $b_{1,1}$ 192-5°, 1.4530, 0.9377; H , b_1 129-33°, 1.4363, 1.0216. The yields were 60-6%. From the acids were prepd. in the usual manner the *cyclopropylmethylalkyl acetic acids*, $C_6H_5CH_2CH(CO_2H)R$, where R is C_4H_9 , $b_{1,4}$ 112-5°, 1.4469, 0.9375; C_6H_{11} , $b_{1,1}$ 130-2°, 1.4498, 0.9253; C_7H_{15} , b_2 136-9°, 1.4509, 0.9236; C_8H_{17} , $b_{1,1}$ 146-9°, 1.4529, 0.9142; C_9H_{19} , $b_{1,3}$ 162-4°, 1.4545, 0.9105; $C_{10}H_{21}$, $b_{1,7}$ 176-8°, 1.4553, 0.9004; $C_{11}H_{23}$, m 27-8°, b_1 186-9°; $C_{12}H_{25}$, m 29-30°, b_3 191-5°; $C_{13}H_{27}$, m 35-7°, $b_{1,3}$ 176-9°. The yields were 86-94%. No appreciable bactericidal effect appeared until the alkyl group was C_8H_{17} or larger, thus indicating as in previous researches that mol. wt. of the whole mol. plays an important role. No marked difference was found between mols. contg. 5-, 6- or 3-membered rings provided the mol. wt. was approx. the same.

C. J. WEST

Di(cyclohexylalkyl)acetic acids. LETHA A. DAVIES AND ROGER ADAMS. Univ. of Ill. *J. Am. Chem. Soc.* 50, 2297-8 (1928); cf. preceding abstr.—The following *di-Et di-[ω-cyclohexylalkyl]malonates* were prepd., with the general formula $C_6H_{11}(CH_2)_x-C(CO_2Et)_2(CH_2)_yC_6H_{11}$ (b. p., n_D^{20} and d_4^{20} are given). x and y are 0, 2, $b_{1,1}$ 192°, 1.4747, 1.016; 1, 2, b_2 186-8°, 1.4725, 1.003; 2, 2, $b_{1,1}$ 200-2°, 1.4722, 0.9931; 2, 3, $b_{1,1}$ 210-1°, 1.4713, 0.9928; 3, 3, b_2 216-8°, 1.4710, 0.9811; 2, 4, $b_{1,1}$ 208-10°, 1.4710, 0.9817. *Di-[ω-cyclohexylalkyl]acetic acids*, $C_6H_{11}(CH_2)_xCH(CO_2H)(CH_2)_yC_6H_{11}$, were prepd. as

follows: x and y are 0,2, b_4 182–6°, n_D^{25} 1.4852, d_4^{20} 0.9915; 1,2, b_4 207–8°, m . 50–1°; 2,2, $b_{1,4}$ 210–3°, m . 73–6°; 2,3, b_3 213–4°, m . 46.5–7°; 3,3, b_3 216–8°, m . 42.5–5°; 2,4, b_4 221–3°, n_D^{20} 1.4831, d_4^{20} 0.9647. These acids were no more effective bactericidally than those mols. contg. the same no. of C atoms which have only 1 ring present.

C. J. WEST

Separation of the optical isomers of a spirocyclic compound of the allene type. H. J. BACKER AND H. B. J. SCHURINK. *Verslag. Akad. Wetenschappen Amsterdam* 37, 384–5 (1928).—The prepn. of $\text{CH}_2\text{CH}(\text{CO}_2\text{H})\cdot\text{CH}_2\cdot\text{C}\cdot\text{CH}_2\cdot\text{CH}(\text{CO}_2\text{H})\cdot\text{CH}_2$ (Fecht,

C. A. 2, 75) has been improved and a yield of 80% obtained. The brucine salt, after decompn. with NH_4OH , gives an optically active NH_4 salt: if λ in μ is 656.3, 589.5, 546.3, 486.1, $[\alpha]$ is 0.11°, 0.13°, 0.15°, 0.19° and $[M]$ is 1.9°, 2.3°, 2.6°, 3.4°. The free acid being little sol. in water, its ether soln. has been examd. $[M]_D = 1.9^\circ$.

$\text{PhCH} \begin{array}{c} \diagup \text{OCH}_2 \\ \diagdown \text{OCH}_2 \end{array} \text{C} \begin{array}{c} \diagup \text{CH}_2\text{O} \\ \diagdown \text{CH}_2\text{O} \end{array} \text{CHPh}$, m . 162°; its crystals show about $\alpha_D = 2^\circ$ per mm.

but do not exhibit any optical activity when dissolved in alc., EtOAc or CHCl_3 . The x-ray pattern shows that the Ph groups must be located on the general axis of the mol. as indicated by the above formula.

A. L. HENNE

Tautomerism of cyclopentadienes. I. Some derivatives of methylcyclopentadiene. FRANK R. GOSS AND CHRISTOPHER K. INGOLD. Univ. of Leeds *J. Chem. Soc.* 1928, 1268–78.— $\text{CH}_2(\text{CO}_2\text{Me})_4$ (16 g.) and 20 g. Me dibromo- β -methylglutarate, added successively to MeONa (5 g. Na and 60 g. MeOH) give 12 g. of the Na salt (I), bright yellow, m . 270° (decompn.) and gives a deep violet color with FeCl_3 , of Me 5-methyldicyclopenten-3-ol-1,2,4-tricarboxylate, b_1 180°; Et ester. Digesting I 72 hrs. with 30% MeOH-KOH gives the di-K deriv., yellow, of MeH 5-methyldicyclopenten-3-ol-1,2 (or 1,4)-dicarboxylate, viscous liquid, which gives a deep violet color with FeCl_3 . Boiling I with an excess of EtI in EtOH for 24 hrs. gives Me 5-methyl-2 (or 4)-ethyldicyclopentan (or cyclopenten)-3-one-1,2,4-tricarboxylate, b_4 210°. Any but the Et deriv., boiled with HCl for 2 hrs., gives 5-methyldicyclopentan (or penten)-3-one-1-carboxylic acid (IV), m 60°; oxime, m . 216° (decompn.). The acid gives no color with FeCl_3 ; on oxidation it yielded only $(\text{CO}_2\text{H})_2$. Me 3-methyl- Δ^2 -cyclopropene-1,2-dicarboxylate and $\text{NCCHNaCO}_2\text{Me}$ give about 15% of Me 3-methyl-1,2-dicarboxymethoxycyclopropane-3-cyanoacetate, b_{10} 200°; with MeONa at room temp. for 12 hrs. and then boiled 4 hrs., there result 2 forms (II and III) of Me 3-amino-1-methyldicyclopentene (or cyclopentadiene)-2,4,5-tricarboxylate; III, m . 186° (decompn.), is extd. from the aq. soln. by Et_2O ; on standing it is converted into the more stable II; the mother liquor, satd. with CO_2 and extd. with Et_2O , gives II, m . 130° (decompn.); II gives a red ppt. with PhN_2X ; neither II nor III gives any noticeable color with FeCl_3 . II with 3 N MeOH-KOH for 24 hrs. gives di-Me H 3-amino-1-methyldicyclopentene-2,4,5-tricarboxylate, m . 226° (decompn.); FeCl_3 gives an intense purple color; the K salt is yellow. Boiling II with HCl for 1 hr. gives IV. Oxidation of II with H_2O_2 and FeSO_4 gives α - and β -methylglutamic and β -acetylacrylic acid. Et 3-amino-1-methyldicyclopentane-2,4,5-tricarboxylate (cyclopentadienetricarboxylate), m . 107°; Na salt, yellow. Di-Et H ester, m . 199°. The Na salt and MeI give the Me deriv., m . 113°; Et deriv., m . 118°.

C. J. WEST

Diveratrylidene and divanillylidene compounds of cyclohexanone, comprising several new indicators. B. SAMDAHL. Univ. Oslo. *J. pharm. chim.* 7, 162–73 (1928).—The prepn. of 9 new compds. is based on the type reaction: $-\text{CH}_2\text{COCH}_3 + 2 \text{OCH}_2\text{R} \rightarrow -\text{C}(\text{CHR})\cdot\text{CO}\cdot\text{C}(\text{CHR})-$ (Wallach, *Ber.* 29, 1595 (1896)). The 3 cyclohexanones $\text{C}_6\text{H}_{10}\text{CO}$ (I), p - $\text{MeC}_6\text{H}_4\text{CO}$ (II) and m - $\text{MeC}_6\text{H}_4\text{CO}$ (III) are made to react with 3 aldehydes: 3,4-(MeO) $_2\text{C}_6\text{H}_3\text{CHO}$ (IV) (Rosenmund, *C. A.* 5, 893); 3,4-MeO(AcO) $\text{C}_6\text{H}_3\text{CHO}$ (V) (Pschorr, *Ber.* 32, 3407 (1899)), and 3,4-MeO(HO) $\text{C}_6\text{H}_3\text{CHO}$ (VI). The following compds. are described: (1) I-IV, $\text{C}_{23}\text{H}_{32}\text{O}_8$, m . 149–50°; (2) II-IV, $\text{C}_{23}\text{H}_{30}\text{O}_8$, m . 154–5°; (3) III-IV, $\text{C}_{23}\text{H}_{30}\text{O}_8$, m . 134–5°; (4) I-V, $\text{C}_{23}\text{H}_{32}\text{O}_7$, m . 190°; (5) II-V, $\text{C}_{27}\text{H}_{34}\text{O}_7$, m . 189°; (6) III-V, $\text{C}_{27}\text{H}_{34}\text{O}_7$, 141–2°; (7) I-VI, $\text{C}_{27}\text{H}_{32}\text{O}_6$, m . 179–80°; (8) II-VI, $\text{C}_{27}\text{H}_{32}\text{O}_6$, m . 169°; (9) III-VI, $\text{C}_{27}\text{H}_{32}\text{O}_6$, m . 171–2°. In the prepn. of 1. and 3, Na alcoholate was used as a catalyst; in all others concd. HCl. To prep., e. g., No. 4, warm 40 g. of V with 10 g. of I on a water bath till melted, add 2 cc. concd. HCl with stirring, cool the red liquid; after 12 hrs. wash with H_2O (violet soln.), then with cold EtOH; then take up with boiling alc. and recrystallize from hot alc. The yields were nearly quant. in 1, 2, 4 and 5, about 80% in 7 and 8, and 50% in 3, 6 and 9. Nos. 7 and 8 form orange crystals, all others are lemon-yellow. No. 7 after the 5th crystn.

yields yellow crystals showing intense yellow fluorescence in ultra-violet light ($\lambda = 366\mu$); the orange crystals are indifferent to this light. The yellow crystals slowly turn back to orange. All these compds. (1-9) give a deep red-violet color with concd. H_2SO_4 (cf. Boedtker, *C. A.* 22, 585). Nos. 7, 8 and 9 in 0.1% alc. soln. (65%) are very sensitive indicators towards acids (greenish yellow) and alkalies (orange-red). They indicate a range of p_{H} 7.8-9.4 detd. by the method of Sørensen-Palitzsch (*C. A.* 4, 1929, 1956; 6, 522; 9, 2918). Changes of 0.1 in p_{H} are marked by distinct changes of color. The indicators are about twice as sensitive as phenolphthalein in indicating addns. of 0.01 *N* NaOH to CO_2 -free H_2O . S. WALDBOTT

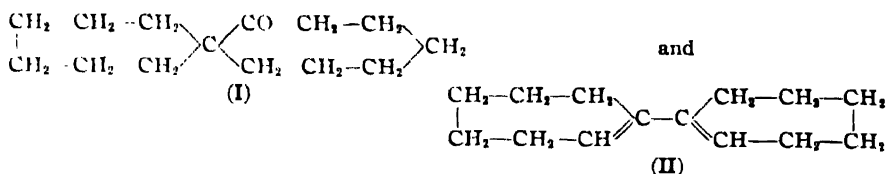

Orientation phenomena with α -methylcyclohexanone. R. CORNUBERT. *Compt. rend.* 186, 441-2 (1928); cf. *C. A.* 21, 3046.—When α -methylcyclohexanone is methylated with Me_2SO_4 , ethylated with EtBr, or allylated with $\text{C}_3\text{H}_7\text{Br}$ by the NaNH_2 method, 86, 85 or 88% of the resulting compds. are of the type $-\text{CH}_2\text{COCRR}'-$, while 14, 15 or 12% are of the type $-\text{CHRCOCHR}'-$. In order to det. whether this ratio is due to a "mol. orientation reflex," or the secondary influence of the reagents, C. investigates the action of NaOH (possibly present in NaNH_2), HCl and NaHSO_4 on each of the pure isomers and finds that no isomerization takes place. It is thus believed that the introduction of Na in the mol. gives generally 85% $-\text{CH}_2\text{COCNaMe}-$ and 15% $-\text{CHNaCOCHMe}-$. Kötze and Steinhorst (*C. A.* 5, 1407) found that during the introduction of Cl into the mol., the formation of $-\text{CHClCOCHMe}-$ was much favored. The polarity of Cl and Na being opposite an explanation of the orientation may possibly be sought there. A. L. HENNE

Quinitrols and quinamines. K. FRIES AND G. OEHMKE. *Tech. Hochschule, Braunschweig. Ann.* 362, 1-24 (1928).—The constitution of the quinitrols of Zincke is still in dispute; they are considered as nitro compds. and as nitrites of quinols. The following study of the behavior of these compds. with alc. alkali indicates that they are nitro compds. and not esters. 3,5-Dibromo-1,4-methylquinitrol (I), suspended in 5 parts ice-cold EtOH and treated with an ice-cold mixt. of 5 parts EtOH and 5 parts 30% KOH for 10 secs. (soln.), gives 70% of 1-methyl-1-nitro-2-ethoxy-3,5-dibromo-4-ketobenzene 1,2,3,4-tetrahydride (II), m. 145° (evolution of NO); slight warming with NaOH causes soln., with which acids ppt. III. AcOH-HBr and II in the cold give 5,3,4-Br(O_2N)(HO) $\text{C}_6\text{H}_3\text{Me}$ (IV). II is rather stable towards cold concd. H_2SO_4 ; warming gives a brown, amorphous product. Reduction of II with Zn and concd. HCl gives 3,4-Br(HO) $\text{C}_6\text{H}_3\text{Me}$. With 2 parts cold $\text{C}_6\text{H}_5\text{N}$, 18 g. II gives 7 g. IV and 6 g. 1-methyl-1-nitro-2-ethoxy-3,3,5-tribromo-4-ketobenzene 1,2,3,4-tetrahydride (V), m. 92° , which does not react with cold NaOH or H_2SO_4 . Reduction of V gives 3,5,4-Br $_2$ (HO) $\text{C}_6\text{H}_2\text{Me}$. If I is allowed to stand 2 days with the cold EtOH-KOH, there results 1-methyl-2-ethoxy-3,5-dibromo-4-hydroxybenzene (III), m. 91° (*Ac deriv.*, m. 67°). 2-MeO deriv. corresponding to II, m. 126° ; $\text{C}_6\text{H}_5\text{N}$ gives the 2-MeO deriv. corresponding to V, m. 105° . The Me ether corresponding to III m. 60° (*Ac deriv.*, m. 104°). With HBr III gives dibromocresorcinol, m. 85° (*Ac deriv.*, m. 67°). III and dil HNO_3 or NaNO_2 give 1-methyl-2-ethoxy-3-bromo-4-hydroxy-5-nitrobenzene, yellow, m. 73° ; fuming HNO_3 gives 1-methyl-1-nitro-2-methoxy-3,5-dibromo-4-ketobenzene 1,4-dihydride, decmps. about 75° . Dibromo-*p*-methylquinol cannot be an intermediate product in the formation of III from I for on treatment with EtOH-KOH there results a deep seated decompn. 3,6-Dibromo-1,2-methylnaphthoquinol with MeOH-NaOH gives the 6-bromo-4-methoxy-1,2-methylnaphthoquinol, m. 155° (*Ac deriv.*, m. 168°); 4-EtO deriv., m. 144° ; 4-HO deriv., m. 182° (*di-Ac deriv.*, m. 147°). Reduction of the 4-MeO deriv. gives 6-bromo-4-methoxy-1-methyl-2-naphthol, m. 143° (*Ac deriv.*, m. 125°). 6-Bromo-4-hydroxy-1,2-methylnaphthoquinitrol, m. 195° (decompn.), results in 60% yield from the di-Br deriv. and 1.5 parts 2 *N* NaOH. Dichloro-*p*-cresol and Br in AcOH give nearly quant. 1-methyl-3,5-dichloro-1-bromo-4-ketobenzene 1,4-dihydride, yellow, m. 106° ; heated on the H_2O bath, it gives 85% of 1-bromomethyl-3,5-dichloro-4-hydroxybenzene, m. 120° . 1-Methyl-1-anilino-3,5-dibromo-4-ketobenzene 1,4-dihydride (VI), yellow, gradually turns black above 100° , results in 40% yield by treating the 1,3,5-Br $_3$ deriv. in 5 parts EtOH with 3 parts PhNH_2 ; it decmps. on warming in any solvent, in the cold in AcOH. Reduction with Zn and AcOH gives dibromo-*p*-cresol. The 1-*o*-toluidino deriv., yellow, m. 112° (decompn.); the *p*-deriv., orange-red, m. 105° (decompn.); the 1-anilino-3,5-dichloro deriv., golden, m. 148° (decompn.). VI in 10 parts AcOH, treated with 25% of the vol. of concd. HCl gives nearly quant. 4-methyl-2,6-dibromo-4'-aminodiphenyl ether, m. 120° (*Ac deriv.*, m. 180°); 2,6-dichloro deriv., m. 99° (*Ac deriv.*, m. 187°); 4-methyl-2,6-dibromo-3'-methyl-4'-aminodiphenyl ether, m. $122-5^\circ$ (*Ac deriv.*, m. 211°). (With A. KUSTER.) 1,3-Dimethyl-1,5-dibromo-4-ketobenzene 1,4-dihydride, m. 59° (75% yield); warming on the H_2O bath gives 90%

of 3-methyl-1-bromomethyl-5-bromo-4-hydroxybenzene, m. 104°. 1,3-Dimethyl-1-anilino-5-bromo-4-ketobenzene 1,4-dihydrate, yellow, m. 107° (decompn.); 1-o-toluidino deriv., yellow, m. 103° (decompn.). 2,4-Dimethyl-6-bromo-4'-aminodiphenyl ether, m. 81° (Ac deriv., m. 163°); the 3'-Me deriv., m. 128° (Ac deriv., m. 187°). C. J. WEST

Stereochemical inversions and cross-saturation processes. A. LAPWORTH AND E. N. MOTTRAM *Mem. Manchester Phil. Soc.* 71, 63-73 (1926-27).—The evidence relating to cross-substitution, or simple stereochem. inversion, and cross-satn. processes is discussed. The former appears to be general when a linking between satd. C and halogen or O is involved in a substitution process in aq. or alc. soln. This is seen, for example, in Holmberg's expts. on halogenated succinic acid (cf. *C. A.* 20, 1600, 3281), or in the changes in optical rotatory effect observed when compds. of the acetochloroglucose type are used as "intermediates" in syntheses in the sugar group, or, finally, in the contrast between the reactions of esters of different types, *e. g.*, sulfonates as compared with carboxylates (Ferns and Lapworth, *C. A.* 6, 1742). When halogens, halogen hydrides, or hypohalogen acids are added to a pair of doubly-linked C atoms, cross-satn. usually takes place and does not necessarily mean that stereochem. inversion must have occurred at some stage in the reaction. Conversely, on elimination of the same elements, cross-desatn. results. It is suggested that in the series of reactions, cyclohexene \rightarrow cyclohexene chloro- or bromohydrin \rightarrow cyclohexene oxide \rightarrow cyclohexanediol, each one is a cross-reaction, resulting finally in a *trans*-compd. Oxidation of cyclohexene by KMnO_4 , however, results in the formation of the *cis*-isomeride of cyclohexanediol. It is possible that the latter case may be best explained by the intermediate formation of a ring compd. with the Mn. B. C. A.

Dehydration of the pinacol of cycloheptanone. MARCEL GODCHOT AND MISS G. CAUQUIL. *Compt. rend.* 186, 767-9 (1928).—The dehydration of 1,1'-dihydroxydi-cycloheptane, m. 78°, is easily realized with dil. H_2SO_4 or $\text{H}_2\text{C}_2\text{O}_4$. Two products are obtained.

I m. 72°; it does not give a semicarbazone or an oxime; by reduction with Na and abs. alc., an alc. $\text{C}_{14}\text{H}_{24}\text{O}$, m. 41°, is obtained whose phenylurethane, m. 156°; its oxidation with HNO_3 (d. 1.40) at 100° gives $(\text{CH}_2)_5\text{C}(\text{CO}_2\text{H})(\text{CH}_2)_5\text{CO}_2\text{H}$, m. 116°, and $(\text{CH}_2)_6\text{C}(\text{CO}_2\text{H})_2$. II b₁₀, 149-50°, d₁₀ 0.9736, n_D²⁰ 1.525; its oxidation with KMnO_4 yields mostly pimelic acid.

A. L. HENNE

Oxidation reactions. II. Oxidation of toluene with nitric acid and nitrogen oxides in the presence of oxygen. P. ASKENASY, E. FLÖD AND CARL TROGUS. *Ann.* 461, 109-30 (1928); cf. *C. A.* 21, 3326. Repetition of Fittig's work (*Ann.* 117, 192; 120, 222 (1861)) showed that the reaction product from boiling 44.1 g. PhMe with 75 g. HNO_3 100 hrs contains BzOH , $p\text{-O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$, $o\text{-O}_2\text{NC}_6\text{H}_4\text{Me}$, CO_2 and traces of picric acid. The results with varying concns. of HNO_3 are shown as curves. Working at 180-5° and 15 atm. pressure with 22.5% HNO_3 , the PhMe reacts almost quant. in 15-20 min.; from 53 g. PhMe, with and without a catalyst (0.0275 g. V_2O_5), there were formed: BzOH , 65.6, 69.6%; $p\text{-O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$, 12.8, 12.3; $o\text{-O}_2\text{NC}_6\text{H}_4\text{Me}$, 1.9, 1.9; picric acid, 0.58, 0.78; CO_2 , 2.4, 2.4; PhMe, 7.5, 8.5; total accounted for, 90.78, 95.48. There is little difference in the results obtained at 10 and 15 atm. pressure. The reaction proceeds very slowly at 150°, is very rapid at 180-5° and above 190° shows a tendency to explode. The effect of changing the concn. of the HNO_3 from 5 to 30% is also studied. $p\text{-O}_2\text{NC}_6\text{H}_4\text{Me}$ is not oxidized by 22.5% HNO_3 on boiling 24 hrs., while some acid is formed with 35-45% acid; at 15 atm. and 180-5°, 92-5% acid is formed with 22.5% HNO_3 in 20 min. $o\text{-O}_2\text{NC}_6\text{H}_4\text{Me}$ under the same conditions of temp. and pressure gives in 18-20 min. 38.4% picric acid, 35.6% CO_2 and 17.35% $o\text{-O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$. BzOH is recovered almost quant. after heating with 22.5% HNO_3 at 180-5° under 10-20 atm. O_2 . Picric acid results in small quantities in the oxidation of various org. compds.; this is specially true of *o*-substituted C_6H_5 rings, in which at least 1 of the 2 *o*-positions is occupied by a C atom. Oxidation in the vapor phase is also discussed.

C. J. WEST

***p*-Cymene studies. X. *p*-Cymylene-2,5-diamine and certain new dyes.** ALVIN

S. WHEELER AND R. W. BOST. Univ. of North Carolina. *J. Am. Chem. Soc.* **50**, 2000-5 (1928); cf. *C. A.* **22**, 228.—Reduction of 5-[4-sulfobenzeneazo]carvacrylamine-HCl with SnCl_2 and HCl gives 77.9% of the HCl salt of *p*-cymylene-2,5-diamine, isolated in an atm. of N in a special app., yellow; *dibenzoate*, m. 280° ; oxidation with CrO_3 gives 2,5-cymo-*p*-quinone, m. 45.5° . The following salts of the amine were prepd.: *HCl*, m. 323° (decompn.); *HBr*, m. 330° (decompn.); *nitrate*, m. 186° (decompn.); *chloroacetate*, m. 144° ; *dichloroacetate*, m. 165° ; *trichloroacetate*, m. 171° ; *bromoacetate*, m. 148° (decompn.); *benzenesulfonate*, decmps. on heating; *o*-chlorobenzoate, m. 161° ; *benzoate*, m. 145° ; *3,5-dinitrobenzoate*, m. 199° (decompn.); *2,4,6-trinitrobenzoate*, m. 130° (decompn.); *picrate*, m. 207° (decompn.). With KSCN there results 2,8-bis[thioureido]-1-methyl-4-isopropylbenzene, m. $235-7^\circ$; KCNO gives 2,5-diureido-1-methyl-4-isopropylbenzene, does not m. 350° . $(\text{CO}_2\text{H})_2$ gives *p*-aminocymyloxamido acid, m. $210-1^\circ$. *Diazo* dyes were prepd. with *m*- $\text{C}_6\text{H}_4(\text{OH})_2$, $\text{C}_{27}\text{H}_{22}\text{O}_6\text{N}_4$, m. $168-70^\circ$; 2- $\text{C}_{10}\text{H}_7\text{OH}$, $\text{C}_{30}\text{H}_2\text{O}_2\text{N}_4$, m. $295-8^\circ$ (decompn.); *p*- $\text{H}_2\text{NC}_6\text{H}_4\text{SO}_3\text{H}$, $\text{C}_{27}\text{H}_2\text{O}_6\text{N}_4\text{S}_2\text{Cl}_2$, m. 100° (decompn.); 2,3,6- $\text{HO}_2\text{C}_6\text{H}_3(\text{SO}_3\text{H})_2$, $\text{C}_{30}\text{H}_{12}\text{O}_{10}\text{N}_4\text{S}_4\text{Na}_4$, m. above 340° ; $\text{C}_{10}\text{H}_7\text{COSH}$, $\text{C}_{10}\text{H}_{22}\text{O}_6\text{N}_6\text{S}_2$, m. $270-2^\circ$ (decompn.); 2- $\text{C}_{10}\text{H}_7\text{SH}$, $\text{C}_{30}\text{H}_{22}\text{N}_4\text{S}_2$, m. $138-40^\circ$; the behavior of these dyes toward wool, silk and cotton and with cold, hot and dil. H_2SO_4 is given. Two dyes of the Eurhodine class were prepd.: *p*- $\text{ONC}_6\text{H}_4\text{NMe}_2$, $\text{C}_{18}\text{H}_{22}\text{N}_4$, blue black, m. 300° (decompn.); *p*- $\text{ONC}_6\text{H}_4\text{OH}$, $\text{C}_{18}\text{H}_{17}\text{ON}_4$, dark brown, m. $200-6^\circ$ (decompn.).

C. J. WEST

Comparative effects of the nitro, carboxyl and sulfonic acid groups on the hydrolysis of aryl halides. WM. DAVIES AND EDNA S. WOOD. Melbourne Univ. *J. Chem. Soc.* **1928**, 1122-31.—A comparison of the effects of the CO_2H , SO_3H and NO_2 groups on the reaction $\text{RCl} + 2\text{KOH} = \text{ROK} + \text{KCl} + \text{H}_2\text{O}$ is reported for compds. of the type *p*- $\text{ClC}_6\text{H}_4\text{X}$, 2,4- $\text{X}_2\text{C}_6\text{H}_3\text{Cl}$, 2,4,6- $\text{X}_3\text{C}_6\text{H}_2\text{Cl}$ and 4,2- $\text{X}(\text{O}_2\text{N})\text{C}_6\text{H}_4\text{Cl}$; the order of activation of the Cl atom is $\text{NO}_2 > \text{SO}_3\text{H} > \text{CO}_2\text{H}$. The activating powers of the 3 groups are, however, very different. So great is that of the NO_2 group in comparison with the other 2 groups that only extremely rough figures can be given. In compds. of the type 2,4- $\text{X}_2\text{C}_6\text{H}_3\text{Cl}$, the Cl in the NO_2 compd. is more than 700,000 times as reactive as that in the SO_3H and more than 200,000 times as reactive as that in the CO_2H acid. The Cl atom in *p*- $\text{ClC}_6\text{H}_4\text{SO}_3\text{H}$ is slightly more mobile than in *p*- $\text{ClC}_6\text{H}_4\text{SO}_3\text{H}$. 2,4- $(\text{HO}_2\text{S})_2\text{C}_6\text{H}_3\text{Cl}$ gives a very sol. *K* salt, and an *amide*, m. $206-7^\circ$. 2,4,6- $(\text{HO}_2\text{S})_3\text{C}_6\text{H}_2\text{Cl}$ forms a very sol. *K* salt, and gives diphenylamine-2,4,6-trisulfonanilide, light gray, m. 227° (decompn.). The original should be consulted for the exptl. details and results.

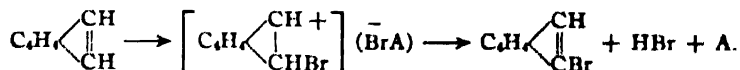

C. J. WEST

Physical properties of *o*-dichlorobenzene. T. S. CARSWELL. *Ind. Eng. Chem.* **20**, 728(1928)—*o*- $\text{C}_6\text{H}_4\text{Cl}_2$, synthesized from purified *o*- $\text{C}_6\text{H}_4\text{ClNH}_2$ through the diazonium compd., showed the following properties: Crystn pt. -16.7° , d_4^{25} 1.3112, d_4^{22} 1.3088, n_{D}^{25} 1.5518, n_{D}^{22} 1.5518.

T. S. CARSWELL

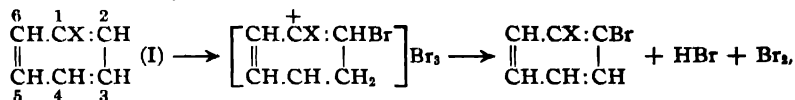

Theory of halogen substitution. P. PFEIFFER AND R. WIZNER. Univ. Bonn. *Ann.* **461**, 132-54(1928).—Gattermann (*Ber.* **22**, 1131(1889)) stated that compds. of the α,α -dianisylethylene series gave a violet color with Br vapor but that this color rapidly disappeared, the original compds. being recovered unchanged. This statement is correct as regards the color change but otherwise incorrect, for the compds. undergo bromination. The Br derivs. behave similarly until the limit is reached when no further bromination can occur. The colors observed intermediately are apparently those of unstable bromo-perbromides; this constitution is deduced from the fact that the depth of color given by a compd. with Br corresponds to that given with concd. H_2SO_4 or with HClO_4 . The reaction is formulated as

follows: $\text{R}_2\text{C}=\text{CH}_2 \xrightarrow{2\text{Br}_2} [\text{R}_2\text{C}(\text{CHBr})\text{Br}] \text{Br}_2 \rightarrow \text{R}_2\text{C}(\text{CHBr})\text{HBr} + \text{HBr} + \text{Br}_2$. It is suggested by analogy that the bromination of C_6H_6 in the presence of a Br carrier A (in the absence of which ordinary addn. occurs) may be expressed:

When $\text{C}_6\text{H}_5\text{N}$ is used as a Br-carrier, the compd. $\left[\text{C}_6\text{H}_5 \begin{array}{c} \diagup \text{CH} \cdot \text{C}_6\text{H}_5\text{N} \\ \text{CHBr} \end{array} \right] \text{Br}$ is the intermediate formed. Again, the *o,p*-directive effect of certain groups X(HO, MeO, NH_2 , etc.) receives explanation if it be assumed that in I the CH:CH linking 5,6 and the group X confer polar properties on the attached C atom (1) as similar groups are known

to do in the case of the types: $[R_2C^+-R]X$, $[R_2C^+-OH]X$, $[R_2C^+-OMe]X$, $[R_2C^+-NH_2]X$ and $[(H_2N)_2C^+-NH_2]X$. The bromination of PhX can thus be written:

p-substitution depending on a 1,4-conjugation-additive process. When X is NO_2 , the "negative" effect of this group is to cause the appearance of the positive charge in the 4-position, the position farthest from X ; as a result, *m*-substitution occurs. (*p*- $MeOC_6H_4$)₂C.CH₂, prepd. either from (*p*- $MeOC_6H_4$)₂CO and $MeMgI$ or from $AcOEt$ and *p*- $MeOC_6H_4MgBr$, is converted by Br (1 mol.) in C_6H_6 or CCl_4 , into the *β*-bromo deriv. (II), m. 84°, whose constitution follows from its oxidation to (*p*- $MeOC_6H_4$)₂CO. II is converted by Br in CCl_4 into the *β,β*-di-*Br* deriv. (III), m. 93–4°, also obtained by the action of the $MeOH$ - KOH upon the *β,β,β*-tri-*Br* deriv., m. 114° (from bromal and $PhOMe$ with concd. H_2SO_4). In $AcOH$, Br and III give the *β,β,3,3'*-tetra-*Br* deriv., m. 150°, also obtained from Br and (*p*- $MeOC_6H_4$)₂C:CH₂. Oxidation gives (3,4- Br (MeO) C_6H_3)₂CO. *p*- $MeOC_6H_4MgBr$ and Me_2CHCO_2Et give *α,α*-dianisyl-*β,β*-dimethylethylene, m. 64°. *α,α*-Dianisyl-*β*-methyl-*β*-bromoethyle, m. 57°; an excess of Br in CCl_4 gives *α,α*-dibromoanisyl-*β*-methyl-*β*-bromoethyle, m. 131°. *α,α*-Di-*p*-dimethylaminophenylethylene with 1% Et_3O-I yields an iodide periodide, dark violet, m. 107°, decomps. 150°; bromoperochloride, dark blue powder, changing to light green in a few hours; $NaClO_4$ gives the bromoperochlorate, deep blue. A table is given of the colors shown when Br , concd. H_2SO_4 or $HClO_4$ acts on a no. of *α,α*-diarylethylenes of the type $Ar_2C^+CX_2$, where X or Y is H , Me , Br or Cl . C. J. WEST

Benzylideneaniline and benzylidene-*p*-toluidine as ammonio aldehyde acetals. HAROLD H. STRAIN. Stanford Univ. *J. Am. Chem. Soc.* 50, 2218–23(1928).—Exptl. evidence is presented to show that $PhCH:NPh$ and *p*- $MeC_6H_4CH:NPh$ are aldehyde-acetals of the NH_3 system of compds. Allowed to stand in liquid NH_3 for 30–35 days there results amarine and $PhNH_2$ or *p*- $MeC_6H_4NH_2$; the reaction was completed in 10–14 hrs. by heating in the presence of NH_4Cl at 120–50°. With KNH_2 in liquid NH_3 , at room temp., the bases undergo the Cannizzaro reaction, yielding benzylphenylbenzamidine, identified as the benzenesulfonyl deriv., m. 148°, and benzyl-*p*-tolylbenzamidine, m. 127–7.5°, also prepd. synthetically. With an alkali cyanide in liquid NH_3 , these bases undergo the benzoin condensation, forming benzoinanilide, yellow, with a greenish fluorescence, softens at 185°, m. 200°, and benzoin-*p*-tolyl-*p*-toluide, m. 122°. $PhCH:NPh$ is nitridized with difficulty giving tar-like decompn. products with a small quantity of $PhCN$. When treated with small quantities of alkali, polymerized compds. are formed; $PhCH:NHPh$ gives a compd. $C_{11}H_{11}N_3$, m. 132–4°, which forms a sol. HCl salt. The polymer from *p*- $MeC_6H_4CH:NPh$, $C_{11}H_{11}N_3$, m. 136–7°. C. J. W.

4-Amino-5-bromo-1,3-dimethylbenzene. ALVIN S. WHEELER AND R. E. THOMAS. Univ. of North Carolina. *J. Am. Chem. Soc.* 50, 2286–7(1928).—1,3,5,4- $Me_2BrC_6H_3NH_2$ yields a HCl salt, which sublimes without decompn.; the *Bs* deriv. m. 186°. Through the diazo reaction the xenol, m. 228–30°, was obtained, whose *Me* ether b. 232°, d_4^{25} 1.362; *Et* ether, b. 246°, d_4^{25} 1.290. The diazo soln. with HCl and Cu gives the 4-*Cl* deriv., b. 250°. 1,3-Xyl-5-bromo-4-nitrile, m. 86–7°. 1-[5-Bromo-1,3-xyl-4-azo]-2-azonaphthol, red, m. 136°; the phenol deriv., orange, m. 166°. C. J. WEST

Second new method for the complete resolution of externally compensated acids and bases. A. W. INGERSOLL. Vanderbilt Univ. *J. Am. Chem. Soc.* 50, 2264–7(1928); cf. *C. A.* 19, 1415.—Continuing his earlier work, I. describes the resolution of a base when the half racemic salt, *d*-*B*-*dl*-A is less sol. than the inactive salt, *dl*-*B*-*dl*-A. *dl*-Isodiphenylhydroxyethylamine (I) (42.6 g.) and 48 g. *d*-camphor-10-sulfonic acid (II) in 1 l. H_2O , fractionally crystd., gives 35.2 g. of the pure *d*-I-*d*-II, m. 207–8° (all m. ps. cor.), $[\alpha]_D^{25}$ 61.2°; it is sol. in about 59 parts H_2O at 25°. *d*-I agrees in properties with that of Read and Steele (*C. A.* 21, 2254). From the more sol. fractions there was isolated *l*-I-*d*-II, m. 205–6°, $[\alpha]_D^{25}$ –37.5°; soly. in H_2O , 32 parts at 25°. A sample of base (16 g.) recovered from the intermediate fractions (46% excess *l*-I) was combined with *dl*-II in 450 cc. H_2O , so that about half of the total salt sepd. on cooling; by systematic crystn. was obtained 12.7 g. pure hydrated *l*-I-*dl*-II, m. 206–7°, $[\alpha]_D^{25}$ –50.3°; soly. in H_2O , 42 parts at 25°; from this *l*-I was obtained, m. 115.2°, $[\alpha]_D^{25}$ –125.6°. *d*-I-*dl*-II, $[\alpha]_D^{25}$ 48.2°. *dl*-I-*dl*-II, m. 198–9°. C. J. WEST

Action of cuprous hydride on diazonium salts. A combined Sandmeyer-Gattermann reaction. PANCHANAN NBOGI AND ANIL K. MITRA. Presidency College, Calcutta. *J. Chem. Soc.* 1928, 1332-3.—The action of CuH at 0° upon diazonium salts gives as a main product an aryl halide, or a phenol from a diazonium sulfate in H₂SO₄, and Ph₃ on addn. of alc. to the H₂SO₄ soln. A small quantity of the diazonium salt is, however, reduced, the corresponding hydrocarbon being formed. Results are given for a no. of amines. C. J. WEST

Interaction of benzoyl chloride and diazomethane together with a discussion of the reactions of the diazenes. WM. BRADLEY AND ROBERT ROBINSON. Univ. of Manchester. *J. Chem. Soc.* 1928, 1310-8.—BzCl and CH₂N₂ give BzCHN₂, m. 48-8.5°, yields of 91% being obtained. BzBr behaves similarly. The mechanism of the reactions of the aliphatic diazo compds. is discussed. C. J. WEST

Reaction between organomagnesium halides and aryl sulfonates. HENRY GILMAN AND LLOYD L. HECK. Iowa State Univ. *J. Am. Chem. Soc.* 50, 2223-30 (1928).—Alkylation is not the only reaction that takes place when alkyl sulfonates are treated with RMgX; alkyl halides are also formed. The following reactions are proposed to account for the formation of these compds.: $RSO_2O-Alkyl + R'MgX \rightarrow R' alkyl + RSO_2OMgX$; $RSO_2OMgX + RSO_2O-Alkyl \rightarrow Alkyl X + (RSO_2O)_2Mg$. According to these reactions the yield of alkylation product should be increased when 2 mols. of the sulfonate are used with 1 mol. of RMgX; this is verified by expt. When 2 mols. of esters are used for 1 of RMgX the R-alkyl and RX compds. are formed in essentially equiv. quantities. The correctness of the 2nd reaction was established by treating β -C₁₀H₇SO₃H with MeMgI to form β -C₁₀H₇SO₃OMgI and then treating this salt with *p*-MeC₆H₄SO₃Bu, to form BuI and (β -C₁₀H₇SO₃O)₂Mg. Various reactions are reported between sulfonates and RMgX compds. Mg cyclohexylsulfonate crystals with 6H₂O; Mg *β*-naphthalenesulfonate is anhyd. The reactions proposed above have a direct bearing on the formula for the Grignard reagent proposed by Jolibois. C. J. WEST

The action of magnesium on several *p*-bromomethylene derivatives of benzene. RAYMOND QUELET. *Compt. rend.* 186, 764-7 (1928) - *p*-Bromoallyl-, propenyl-, -Δ¹-butenyl-, -Δ³-butenylbenzene react normally with Mg. *p*-Bromostyrolene does not react. If the yield of the Grignard reagent is detd. by the MgO method or the I method, contradictory results are obtained. The low results given by the 2nd method are explained by assuming that compds. are formed analogous to *p*-BrMgC₆H₄CH(C₆H₅)CH·CHMe)CHMeMgBr. These compds. would react with H₂O, but not with I. In each case, a secondary reaction takes place which is substantially a Wurtz reaction. (*p*-C₆H₄CH·CHMe)₂, m. 185-6° has been isolated; it is little sol. in benzene, giving a blue fluorescence. A. L. HENNE

Grignard reaction. Preparation of tetraphenylphosphonium salts. JAKOB DOBONOV AND HERMANN MEDOX. Landwirtschaftl. Inst. Saratow. *Ber.* 61B, 907-11 (1928)—Ph₃P, m. 79.5°, is prepd. in a 76% yield from PhMgBr and PCl₃ in ether in a H atm. under const. cooling. If its Et₂O soln. is treated with PhMgBr in ether and a current of O is blown through the cooled mixt. during 1.5 hrs. Ph₄PBr is obtained; when the latter is anhyd. it m. 287°; it is sol. in alc. or CHCl₃, insol. in ether or C₆H₆, little sol. in cold H₂O, very sol. in hot H₂O. Ph₄POH is obtained from the bromide by long digestion with fresh Ag₂O; it is unstable; the carbonate is unstable too. The chloride crystallizes with 5H₂O; it m. 265° when anhyd. The sulfate crystallizes with 18H₂O; it does not melt sharply. The nitrate is anhyd. and m. 284°. The iodide m. 333°. A. L. HENNE

Action of thiocyanogen upon *O,N*-disubstituted hydroxylamines and primary amines. LAUDER W. JONES AND ELMER E. FLECK. Princeton Univ. *J. Am. Chem. Soc.* 50, 2018-28 (1928).—The (SCN)₂ from 11.3 g. Ph(SCN)₂ and 4.8 g. Br and 9.2 g. EtONH₂ give 40% of *O,N*-diethyl-*N*-thiocyanohydroxylamine, EtO(Et)NSCN, b₇ 45-6°; it decomps. rapidly on exposure to the air at room temp. Acid hydrolysis gives HCN, HSCN, H₂SO₄ and EtONEtH₂Cl, identified as EtONEtCONHPh. Alk. hydrolysis gives AcH, EtNH₂, NH₃ and K₂S₂O₈. *O,N*-Dibenzylcarbethoxyhydroxamic ester, b₇ 200-3°. *O,N*-Dibenzylhydroxylammonium thiocyanate, m. 91°, and *O,N*-dibenzyl-*N*-thiocyanohydroxylamine, m. 50-2° (47% yield), result from PhCH₂ONH(C₆H₅) and (SCN)₂. Alk. decompn. of EtONH₂ gives AcH and EtNH₂ when a 2% KOH soln. is heated at 180°; PhCH₂ONHCH₂Ph likewise gives (at 150°) BzH and PhCH₂NH₂. Ph₃CNH₂ and (SCN)₂ give triphenylmethylammonium thiocyanate, m. 173°, and triphenylmethylthiocyanamine, m. 142° (55% yield); the final product of the rearrangement of the latter with CaO is Ph₃C·NPh. Benzylthiocyanamine is an oil, which could not be purified; with HCl it gives PhCH₂NH₂Cl; with picric acid, the corresponding picrate. Evapn. to dryness of a soln. of PhCH₂ON(C₆H₅)H.HCl and KCNO gives 30% of

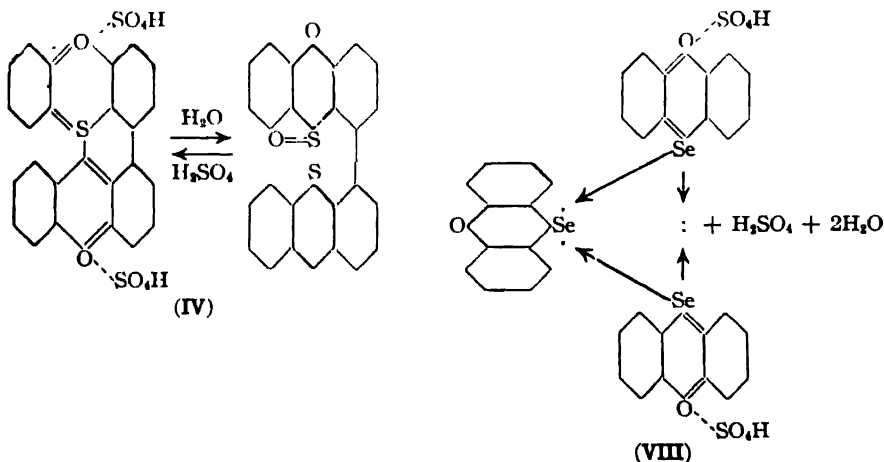

α, α' -benzylbenzylthiourea, m. 98–9°; α, α' -benzylbenzylthiourea, similarly prepd. in 24% yield, m. 94–5°. When the thiocyanate is dry-distd., the products are BzH and $\text{PhCH}_2\text{CSNH}_2$.

C. J. WEST

Diphenylamine- and triphenylamine-arsonic acids. II. O. WINTERSTEINER AND H. LIEB. *Ber.* 61B, 1126–35 (1928).—*p*- or *m*-Arsanilic acid does not condense with PhBr in the presence of Cu and K_2CO_3 in PhNO_2 or AmOH. *o*-Arsanilic acid, after a long heating at 130–90° with PhBr and CO_2K_2 , a trace of Cu and CuI or KI_2 give 50% *o*- $\text{PhNHC}_6\text{H}_4\text{AsO}_3\text{H}_2$ (I). After a long heating at 165° is obtained *o*- $\text{Ph}_2\text{NC}_6\text{H}_4\text{AsO}_3\text{H}_2$ (II), which is sepd. from I by its insoly. in Me_2CO ; it decomps. 150°. A similar condensation with acetoarsanilic acid yields easily *o*- $\text{PhNAC}_6\text{H}_4\text{AsO}_3\text{H}_2$ (III), decomp. 150°. *o*-Arsanilic acid and *p*- $\text{C}_6\text{H}_4\text{Br}_2$ yield *o*-(*p*- $\text{BrC}_6\text{H}_4\text{NH}$) $\text{C}_6\text{H}_4\text{AsO}_3\text{H}_2$ (IV) m. 80°, and *o*-[(*p*- BrC_6H_4) $_2\text{N}$] $\text{C}_6\text{H}_4\text{AsO}_3\text{H}_2$ (V), m. 215°. *o*-Arsanilic acid condenses with *o*- $\text{BrC}_6\text{H}_4\text{CO}_2\text{H}$, yielding quant. *o*- $\text{HO}_2\text{CC}_6\text{H}_4\text{NHC}_6\text{H}_4\text{AsO}_3\text{H}_2$ (VI), decomp. 237°; with *m*- $\text{BrC}_6\text{H}_4\text{CO}_2\text{H}$, the corresponding condensation product (VII) decomp. 238°. The condensation with *p*- $\text{BrC}_6\text{H}_4\text{CO}_2\text{H}$ is more difficult but the corresponding product (VIII) is obtainable and decomp. 210°. *p*- and *m*- PhNO_2 give a 60% condensation yield; *o*-(*p*'- $\text{O}_2\text{NC}_6\text{H}_4\text{NH}$) $\text{C}_6\text{H}_4\text{AsO}_3\text{H}_2$ (IX) decomp. 245–50°, while the *m*'-compd. (X) decomp. 205–10°, the *o*'-deriv. (XI) decomp. 245°, and is obtained by heating at only 100°. By melting one of the 3 nitrodiphenylamines with H_3AsO_3 , the yield is only 10% max., and the AsO_3H_2 group goes into the *p*-position. III and concd. HNO_3 are yellow, then green; addn. of H_2SO_4 makes the color blue. IV and HNO_3 are green becoming red after H_2SO_4 addn. V becomes yellow and greenish brown, then brown by analogous treatment; its AcOH soln. becomes green with a drop of H_2SO_4 . VI and HNO_3 are brown; addn. of H_2SO_4 makes the color purple. IX is red with H_2SO_4 ; HNO_3 addn. makes the color yellow.

A. L. HENNE

Cyclic organo-metallic compounds. V. Phenoxselenine and phenoxthionine from phenoxtellurine. Selenylum and thionylum compounds. H. D. K. DREW. *J. Chem. Soc.* 1928, 511–24; cf. *C. A.* 22, 2150.—Phenoxtellurine (I) (3 g.) and 0.35 g. S, heated until reaction sets in and then boiled 10 min., give 2.1 g. phenoxthionine (II), purified by adding a few drops of Br to the CHCl_3 soln., when it m. 58° (Mauthner, *Ber.* 39, 1344 (1906), gives 60–1°). II, warmed with a slight excess of H_2O_2 in AcOH, gives the oxide (III), m. 158–9°; reduction with Zn and AcOH gives II. The prolonged action of H_2O_2 or the action of CrO_3 or KMnO_4 upon II gives the dioxide, m. 147–8°, which is very resistant to reducing agents and is not affected by hot AcOH-HCl. II in cold concd. H_2SO_4 gives a deep violet soln.; after 3 hrs., when the evolution of SO_2 is

complete, decompn. with ice gives mol. proportions of II and III; since neither of these is stable towards H_2SO_4 , they must be combined as a *thionylum compd.* in the colored soln. III in concd. H_2SO_4 gives an intensely purplish violet soln., but SO_2 was not evolved; decompn. with ice gives pure II and a brown amorphous product, m. 215–20° (decompn.), which gives a blue soln. with H_2SO_4 , which is considered to be a complex of the type IV. When III is heated with concd. H_2SO_4 0.5 hr. on the water bath, II and IV are obtained. When the soln. of III in H_2SO_4 is kept only 5 min. before de-

compn. with ice, both **II** and **III** may be isolated, although some **IV** is produced. **I** and powd. Se, boiled gently 0.5-1 hr., give a S-yellow product contg. about 2 mols. **V** and 1 mol. **I**, sepd. by transforming the **I** into its insol. di-Br compd.; *phenoxselenine* (**V**) m. 87-8° and has a faint odor of rose leaves; the halogens in CHCl_3 give halides: *dichloride*, light yellow, m. 127° (decompn.); *dibromide*, orange-red, m. 147-8° (decompn.). With H_2O_2 **V** yields a *dihydroxide*, which loses H_2O at 100° *in vacuo* over H_2SO_4 , giving the *oxide* (**VI**), m. 171-2°, transformed into the *dihydroxide* with H_2O ; both vigorously decomp. H_2O_2 . The deep olive-green soln. of **V** in concd. H_2SO_4 evolves SO_2 ; decompd. with ice after 2 hrs., the soln. gives 57.4% of the original wt. of **V** and **VI** equiv. to 41.2% of **V**; the green soln. may thus consist of triphenoxselenylium dibisulfate (**VII**) together with rather less than a mol. proportion of diphenoxselenylium dibisulfate, both probably in combination with H_2SO_4 mols. **V** (1 g.) in 6 cc. concd. H_2SO_4 , warmed 5 min., cooled and treated with 4 cc. H_2O gives Cu-red **VII** *sulfuric acid dihydrate* (**VIII**), forming a purplish black powder, m. 168°; the H_2SO_4 soln. is olive-green, becoming green on warming. **VIII** is stable in moist air for only a few hrs., being then gradually hydroxylated with loss of color. Cautious diln. of the H_2SO_4 soln. with H_2O gives crystals of **VIII** as well as dark purple crystals, which may be **VIII** deprived of the mol. of attached H_2SO_4 , or a diphenoxselenylium compd. On treatment with cold H_2O **VIII** breaks up quant. into H_2SO_4 , **V** and **VI**.

C. J. WEST

Diphenylene sulfide. CH. COURTOT, L. NICOLAS AND TCHANG HAN LIANG. *Compt. rend.* **186**, 1624-6 (1928); cf. *C. A.* **20**, 2155.—*Diphenylene sulfide* (**I**) on nitration gives *nitrodiphenylene sulfide* (**II**), m. 184°, and *diphenylene sulfinone*. *Aminodiphenylene sulfide* (**III**), m. 133°, from **II** by reduction, gives *chlorodiphenylene sulfide* (**IV**), m. 113-4°, *bromodiphenylene sulfide* (**V**), m. 125-6°, and *iododiphenylene sulfide* (**VI**), m. 87-8°, by the Sandmeyer reaction. With Br_2 in CHCl_3 **I** gives **V** and 2,7-*dibromodiphenylene sulfide* (**VII**) m. 229°. With Mg **V** and **VII** give products from which *diphenylene sulfide-carboxylic acid*, m. 255°, and *-dicarboxylic acid*, m. 320°, are obtained. With SOCl_2 **II** gives **IV**. **V** is similarly obtained. With NH_3 and CuCl **V** gives **III**. 2,7-*Diaminodiphenylene sulfide* gives **VII**, *dichlorodiphenylene sulfide*, m. 205-6°, and *diiododiphenylene sulfide*, m. 219-20°, by the Sandmeyer reaction. Nitration of **V** gives *bromonitrodiphenylene sulfide* (**VIII**), pale yellow needles, m. 264-5°, and *bromodiphenylene sulfinone*, white, m. 171-2°. Reduction of **VIII** gives *bromoaminodiphenylene sulfide* (**IX**), m. 150-1°, which gives **VII** by the Sandmeyer reaction. The absorption spectra of these compds., with the exception of the CO_2H acids, were detd. from $\lambda/2500$ to $\lambda/4300$. The presence of 1 halogen has a bathochromic and hyperchromic effect, least marked with **I**. The effect is increased with 2 halogens, most marked with **I**. The effect of OH , NH_2 and NO_2 is more marked than that of 2 halogens. The bathochromic effect increases with the unsatn. of the S in the series sulfide, sulfinone, sulfone.

PAUL J. CULHANE

Nitration of aromatic thiocyanates and selenocyanates. FREDERICK CHALLENGER AND ARNOLD T. PETERS. Univ. Manchester. *J. Chem. Soc.* **1928**, 1364-75.—In the nitration of *o*- $\text{MeC}_6\text{H}_4\text{SCN}$ the principal product is the 5- NO_2 deriv., m. 117.5-8.5°; the 2nd product is the 4- NO_2 deriv., m. 70-1°; both of these were prepd. in 80% yields through the Sandmeyer reaction. The influence of the SCN group is, therefore predominant. *Phenyl selenocyanate*, b_p 134°, b. 250° (decompn.), results in 50% yield from PhN_2X and KSeCN ; nitration gives the *p*- NO_2 deriv., with a small quantity of the *o*-deriv. Nitration of *p*- $\text{MeC}_6\text{H}_4\text{SeCN}$ gives some 2-nitro-*p*-tolueneseleninic acid, m. 151°, and, as the principal product, *di* 2-nitro-*p*-tolyl diselenide, m. 60°, also obtained by the reduction of the acid with Zn and HCl and by the action of KOH on the SeCN deriv. Nitration without oxidation occurred at -10°, the principal product being the 2- NO_2 deriv., yellow, m. 69-70°; a small quantity of the 3- NO_2 deriv., yellow, m. 150°, is also formed. *p*- $\text{ClC}_6\text{H}_4\text{SeCN}$ and HNO_3 at 3° give principally *di*-*p*-chlorophenyl diselenide with some *p*-chlorobenzeneseleninic acid. At -10° there results principally the diselenide, with a small quantity of the 2- NO_2 deriv., pale yellow, m. 127°. HNO_3 and *p*- $\text{BrC}_6\text{H}_4\text{SeCN}$ give only *p*-bromobenzeneseleninic acid, m. 113°. *p*-Dithiocyanobenzene, m. 100°, slightly volatile with steam; nitration gives a yellow NO_2 deriv., m. 143-4°. *p*-Thiocyanoselenocyanobenzene, m. 109-10°, somewhat volatile with steam. HNO_3 at 3° gives *p*-thiocyanobenzeneseleninic acid, m. 154°. *p*- $\text{NCSC}_6\text{H}_4\text{NHAc}$ and HNO_3 at 3° give 2-nitro-4-thiocyanacetanilide, yellow, m. 138-9°, and a small quantity of 2-nitro-4-thiocyananiline, orange, m. 113°. Prolonged action of HCl on the latter probably gives *di*-3-nitro-4-aminophenyl disulfide, red, m. 169°; this crysts. with Me_2CO , yellow, which loses the Me_2CO at 100°, giving the red compd. 4-Chloro-3-nitrophenyl thiocyanate, m. 63°, from the free base through the diazo reaction; 4-Br deriv., pale yellow, m. 83°; 2-nitro-4-thiocyanophenyl selenocyanate, yellow, m. 147°, gives a purple

color with EtOH-KOH. *p*-Selenocyanacetanilide, m. 206°; HNO₃ at -20° gives the 2-NO₂ deriv., yellow, m. 157°; the corresponding aniline, orange, m. 118°.

C. J. WEST

Cyclic disulfides derived from diphenyl. HARRY J. BARBER AND SAMUEL SMILES. King's College, London. *J. Chem. Soc.* 1928, 1141-9.—A diazotized soln. of 32 g. *o*-H₂NC₆H₄SO₃H (500 cc.) contg. an excess of H₂SO₄ was stirred and warmed with 42 g. KI, giving 80% of *o*-IC₆H₄SO₃Na. *Di-o*-iodophenyl disulfide, m. 133°; 2-iodophenyl Me sulfone, m. 109°, was obtained from the sulfonic acid, m. 108°, by alk. methylation. 2-Iodotoluene-5-sulfonic acid forms a Ba salt, crystg. with 1.5H₂O; the chloride, m. 61-2°; the amide, m. 135°. 4-Iodotoluene-3-sulfonic acid forms a K salt crystg. with 1H₂O; chloride, m. 68°; amide, m. 161-2°. Reduction of the chloride with HI and H₂SO₄ gives di-4-iodo-*m*-tolyl disulfide, m. 104-5°. 1-Iodonaphthalene-2-sulfonic acid forms an anhyd. Ba salt; chloride, m. 94°; sulfonic acid, m. 143°; di-1-iodo-2-naphthyl disulfide, m. 154°. 2-IC₆H₄SO₃Na, boiled with finely divided Cu and a little CuSO₄ and the residue treated with PCl₅, gives about 75% of diphenyl-2,2'-disulfonyl chloride, m. 138°; the dianilide, m. 186°. Reduction with Zn and HCl gives 50-60% of 2,2'-dithioldiphenyl, m. 78-9°. ClCH₂CO₂Na gives 2,2'-dicarboxymethylthioldiphenyl, m. 201-2°. FeCl₃ and the dithiol give almost quant. diphenylene-2,2'-disulfide, yellow, m. 113°; Cu at 250° gives dibenzothiophene; HNO₃ gives the disulfoxide, m. 128°. Diphenylene-2,2'-dithiolcarbonate, m. 101.5°. The dithiol and BzH with HCl give diphenylene-2,2'-mercaptol of BzH, m. 105-6°; the Me₂CO deriv., m. 95°; the benzil deriv., m. 198°. 4,4'-Dimethylthioldiphenyl-2,2'-disulfonyl chloride, m. 117-8°; Zn and HCl give 60% of *m*-MeC₆H₄SH, identified as *m*-tolyl *p*-nitrothiobenzoate, pale yellow, m. 96°. 3,3'-Dimethylthioldiphenyl, m. 50°. 4,4'-Dichlorodiphenyl-3,3'-disulfonyl chloride, m. 179°; 4,4'-dichloro-3,3'-dimethylthioldiphenyl, m. 130°. Diphenyl-4,4'-disulfonic acid, m. 143° (decompn.); mineral acids convert it into an amorphous material of high mol. wt. 1,1'-Dinaphthyl-2,2'-disulfonic acid, analyzed as the K salt; chloride, m. 202-3°. 1,1'-Dinaphthylene 2,2'-disulfide, m. 202°, results from Cu and the disulfide, bright yellow, m. 214°. (*o*-IC₆H₄)₂S and Cu at 180° give thianthrene. C. J. WEST

Guaiacol cacodylate. A. ANGELETTI. *Giorn. farm. chim.* 76, 165-72(1927).—Besides the compd AsMe₂OOH.HOC₆H₄OMe, which is completely decompd. in H₂O, there is a eutectic, m. 18°, contg. 87.3% of guaiacol.

B. C. A.

The strength of the bond between phenolic ethers and an ethylene bridge. H. THOMS AND F. A. HEYDEN. Univ. Berlin. *Festschrift A. Tschirch* 1926, 211-20; *Chem. Zentr.* 1927, I, 2729-30.—The strength of bond between 2 phenolic ethers which are united by an ethylene group was studied by means of eugenol Et ether. By hydrogenation with Pd on BaSO₄ as catalyst, the allyl group was converted into the Pr group of ethylenedieugenol. The hydrogenated compd., which had a pearly aspect, m. 101°. By dissolving in AcOH and adding HNO₃, a di[nitrohydroeugenol] ethylene ether, was formed, m. 167.5°. Suspended in AcOH, added to SnCl₄ in AcOH into which HCl gas was passed, warmed, NaOH added, the liberated base treated with HCl, formed the HCl salt of the amino deriv., m. 245°. It was proved that the NO₂ and the NH₂ group in each nucleus entered the *p*-position to the MeO group. Hydrogenation of the allyl group of the di[eugenol]ethylene ether with Na in EtOH gave an orange odor, a result of a partial cleavage. Cleavage is not brought about by bases in different concns., and therefore in the organism rupture of the ethylene bridge probably does not take place. It probably does take place, however, by the action of nascent H in alc. alkalies. The cleavage products included the compd. C₁₂H₁₆O₃, an ethyleneglycol-[2-methoxy-4-propyl-1-phenyl]ether, and *m*-PrC₆H₄OMe. Besides this cleavage, a partially sym. cleavage occurred, whereby *m*-PrC₆H₄OMe and (CH₂OH)₂, were formed. C. C. D.

Chloromethyl benzyl ether and benzylformal. P. CARRÉ. *Compt. rend.* 186, 1629-30(1928); cf. *C. A.* 20, 581.—Benzyl alc. (I) with HCHO and HCl gas gives chloromethyl benzyl ether, ClCH₂OCH₂Ph (II), b₁₁, 103°, decompg. on distn. at ordinary pressure, and benzylformal, (PhCH₂O)₂CH₂ (III), also obtained by heating I with III. III disproportionates on heating to 330°, giving HCHO, PhMe and BzH. P. J. C.

Isomerism of the styryl alkyl ketones. IV. 4-Hydroxy- and some derivatives of 2-hydroxystyryl alkyl ketones. ALEXANDER MCGOOKIN AND DONALD JAMES SINCLAIR. Univ. of Liverpool. *J. Chem. Soc.* 1928, 1170-7; cf. *C. A.* 20, 2833.—The green Na salt of 5,5'-dibromo-2,2'-dihydroxydistyryl ketone seps. from the red soln. of the monostyryl Me ketone in alkali; acidification gives the free ketone, bright yellow, m. 188°; this is also obtained by the usual condensation methods. The mother liquor gives a colorless form, m. 174.5°, which gives a yellow color in alkali. 2-Hydroxy-4-methoxystyryl Et ketone, m. 123°, from 2,4-HO(MeO)₂C₆H₃CHO, MeCOEt and alkali; the alk. soln. is yellow, turning orange in 5 days. The Pr homolog exists in a yellow and a colorless form, both m. 111-2°.

2-Hydroxy-3-methoxystyryl *Et* ketone, m. 86.5°; the hydrated form, pale yellow, m. 77-9°; the *Pr* homolog m. 82.5°. 3-Nitrostyryl *Me* ketone, pale yellow, m. 99-100°. 4-Hydroxystyryl *Me* ketone, pale lemon-yellow or colorless, m. 111-2°. 4,4'-Dihydroxy-distyryl ketone, yellow, m. 237-8°. 4-Hydroxystyryl *Et* ketone, yellow and colorless needles, m. 115°; *Pr* homolog, yellow or colorless, m. 90°, the yellow hydrate m. 80-3°. 2-Hydroxystyryl *iso-Pr* ketone, yellow, m. 107°, readily passing into the colorless modification, m. 107°; the *tert-Bu* homolog, m. 128°, also exists in a colored and colorless modification; the *isobutenyl* homolog, m. 141°. These ketones belong to 3 classes: those which contain the group $\text{CH}:\text{CHAc}$, whose fission products recombine in alk. soln. to form the distyryl ketones; those which contain the group $\text{CH}:\text{CHCOCH}_2\text{R}$, where R is any alkyl group, whose fission products recombine in alk. media with the formation of high-melting, unsatd. substances of undetd. nature; those represented by the 2-hydroxystyryl ketones described above, on which alkali has no action (other than solvent action) and which are not attacked by boiling concd. HCl. C. J. WEST

Action of bromine on β -phenylbenzalacetophenone. R. BARRÉ AND E. P. KOHLER. Harvard Univ. *J. Am. Chem. Soc.* 50, 2036-40 (1928) - Br and $\text{Ph}_2\text{C}:\text{CHBz}$ in CHCl_3 give a mixt. of the α -Br deriv. I, m. 88.9°, and 1,2-dibromo 1,3-diphenylindene (II), m. 104-5°; the yield of I and II depends upon the presence and the concn. of HBr, which is formed during the bromination. If the CHCl_3 soln. is refluxed immediately after the addn. of the Br, the yield of I is about 90%; if the soln. is allowed to stand at room temp. for 15 hrs., II is also formed. II also results by the action of HBr on I in glacial AcOH. I is not affected by O_3 after 2 hrs.; reduction with Zn dust gives $\text{Ph}_2\text{CHCH}_2\text{Bz}$. II and O_3 give α - $\text{C}_6\text{H}_5\text{Bz}_2$; with boiling EtOH II gives the 1-EtO deriv., m. 130-1°. C. J. WEST

Comparative stability of different isomers with respect to their absorption spectra. Transpositions in the 1-aryl-2-phenyl-2-ethyl-1-butanol series. NMR. RAMAT-LUCAS AND ANAGNOSTOPOULOS. *Compt. rend.* 186, 1626-9 (1928); cf. C. A. 22, 2712 - The 1-aryl-2-phenyl-2-ethyl-1-butanols (I), from the corresponding ketones, Na and EtOH, when passed over infusorial earth at 300-350° at reduced pressure gave 1-aryl-1-phenyl-2,2-diethylethylenes (II). At 400-450° 1-aryl-2-phenyl 1,2-diethylethylenes (III) were obtained. The hydrocarbons II obtained by dehydration and by synthetic methods had practically the same absorption spectra. The curves for the hydrocarbons III obtained by dehydration were displaced towards the visible compared with those obtained by synthesis. This was due to the preponderant formation of the stable forms of the geometric isomers at higher temps. Compds. here prepd. for the 1st time are: 1-*p*-tolyl-2-phenyl-2-ethyl-1-butanone, m. 86°, b_{18} 205° (oxime, m. 205°; semicarbazone, m. 169°); 1-anisyl-2-phenyl-2-ethyl-1-butanone, m. 56°, b_{18} 222° (oxime, m. 180°); 1-*p*-tolyl-2-phenyl-1-butanone, m. 35°, b_{11} 185° (semicarbazone, m. 161°); 1-anisyl-2-phenyl-1-butanone, m. 45°, b_{20} 215-20° (oxime, m. 154°; semicarbazone, m. 118°); 1,2-diphenyl-2-ethyl-1-butanol, b_{20} 209° (phenylurethan, m. 157°); 1-*p*-tolyl-2-phenyl-2-ethyl-1-butanol, b_{11} 205° (phenylurethan, m. 166°); 1-anisyl-2-phenyl-2-ethyl-1-butanol, b_{20} 234° (phenylurethan, m. 122°); 1,1-diphenyl-2-ethyl-1-butanol, b_{11} 186°; 3-*p*-tolyl-4-phenyl-3-hexanol, b_{18} 190°; 1,1-diphenyl-2-ethyl-1-butene, b_{11} 160°; 1-*p*-tolyl-1-phenyl-2-ethyl-1-butene, b_{11} 172°; 1-anisyl-1-phenyl-2-ethyl-1-butene, b_{11} 190°; 3,4-diphenyl-3-hexene, b_{14} 168°; 3-*p*-tolyl-4-phenyl-3-hexene, b_{11} 170°; 3-anisyl-4-phenyl-3-hexene, b_{12} 204°. PAUL J. CULIANE

Synthetic homologs of dl-ephedrine. J. F. HYDE, E. BROWNING AND ROGER ADAMS. Univ. of Ill. *J. Am. Chem. Soc.* 50, 2287-92 (1928). Substituted α -amino propiophenones were prepd. from a bromo ketone and an amine. Compds. of the type $\text{BzCHRNHMe}:\text{HCl}$, where R is (m. p. of the HCl salt given) H, 219°, Me, 176.7°, Et, 190.2°, *Pr*, 183.5-4.5°; BzCH_2NHBu , 214.5°; $\text{BzCH}(\text{NBu}_2)\text{Et}$, 138.40°; of the type $\text{BzCH}(\text{NMe})\text{NHR}$, where R is Et, 183°, *Pr*, 180°, *iso-Pr*, 213.3-5° (free base b_2 105-10°), Bu, 158.9° (free base, b_2 140.2° (some decomposition)), Am, 150°; $\text{BzCH}(\text{MeNEt}_2)$, 167-8°. Reduction of the amino ketones with Pt oxide gives about 90% of α -phenyl- β -methylamino alcs. Compds. of the type $\text{PhCH}(\text{OH})\text{CHRNHMe}$, where R is (m. p. of base and HCl salt given) H, 75.6°, 105.6°; Me, 76.7°, 189-90°; Et, 89-90°, 201-2°, *Pr*, 76.7°, 224-5°; $\text{PhCH}(\text{OH})\text{CH}_2\text{NHBu}$, 58.9°, 218.20°; $\text{PhCH}(\text{OH})\text{CH}(\text{NBu}_2)\text{Et}$, —, 114.6°; compds. of the type $\text{PhCH}(\text{OH})\text{CHMeNHR}$, where R is (m. p. of HCl salt given) Et, 190.1°, *Pr*, 218°, *iso-Pr*, 193°, Bu, 220-1°, Am, 219°; $\text{PhCH}(\text{OH})\text{CHMeNEt}_2$, 205.6°. Blood sugar is increased as the alkyl group on the N is made larger; it is decreased as the alkyl group on the β -C is increased in size; the ketones showed a similar action; the dialkylamino compds. produced no physiol. action. The only homolog which gave a dependable increase in blood sugar was $\text{PhCH}(\text{OH})\text{CHNHMe}$. C. J. WEST

Tautomerism of the α -diketones. The constitution of the two forms of methylbenzylglyoxal. HENRI MOUREU. *Compt. rend.* **186**, 503-5 (1928); cf. *C. A.* **22**, 1341.—Two forms, *A* and *B*, of methylbenzylglyoxal are known. *B* oxidizes in the air, is sol. in alk. solns., gives instantaneously a brown salt with FeCl_3 , a cryst. salt, m. 184-5°, with SbCl_5 , a *Bz* deriv., m. 82-3°, fixes 2 atoms Br in the cold and evolves a gas with the Grignard reagents; *A* does not add Br, reacts only very slowly with SbCl_5 or FeCl_3 , evolves but little gas with a Grignard reagent. The formula $\text{PhCH}_2\text{COCOMe}$ is proposed for *A*, while *B* should be $\text{PhCH} \cdot \text{C(OH)COMe}$.

A. L. HENNE

The action of sulfuric acid on aromatic acids. Sulfo-aromatic acids. JEAN B. SENDERENS AND JEAN ABOULENC. *Compt. rend.* **186**, 1497 9 (1928).—*m*-Sulfobenzoic acid is best prepd. by heating BzOH with 4 parts of 20% fuming H_2SO_4 for 3 hrs. at 200°. Sulfo-4-*o*-phthalic acid is prepd. by heating *o*- $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_2$ or its anhydride with 4 parts of 20% fuming H_2SO_4 at about 215°. The sulfonation of *o*-toluic acid is effected by heating it with 5 or 6 parts of H_2SO_4 (66° B ϵ .) for 3 or 4 hrs. at 150-160°. $\text{PhCH}_2\text{CO}_2\text{H}$ and $\text{PhCH}:\text{CHCO}_2\text{H}$ cannot be sulfonated by 66° B ϵ . H_2SO_4 . Sulfohydrocinnamic acid is obtained by treating $\text{PhCH}_2\text{CH}_2\text{CO}_2\text{H}$ with 8 parts of 20% fuming H_2SO_4 .

REYNOLD C. FUSON

Thyroxine. II. H. BAGGESGAARD-RASMUSSEN. *Dansk Tids. Farm.* **2**, No. 3 66-9 (1928); cf. *C. A.* **22**, 968. -B-R. has already suggested the constitution of thy-

roxine to be $\text{HO} \begin{array}{c} \text{I} \\ \diagup \quad \diagdown \\ \text{C} \quad \text{C} \\ \diagdown \quad \diagup \\ \text{I} \end{array} \text{O} \begin{array}{c} \text{I} \\ \diagup \quad \diagdown \\ \text{C} \quad \text{C} \\ \diagdown \quad \diagup \\ \text{I} \end{array} \text{CH}_2\text{CH}(\text{NH}_2)\text{CO}_2\text{H}$. The reason for this as-

sumption was that this compd. gives reactions characteristic of diiodo-substituted phenols where the I atoms are in the *o* position to the OH group, also that on fusing with an alkali pyrogallol is formed. Further proof for the correctness of this formula was obtained through the method of synthesis, which was as follows: *p*-nitroaniline $\rightarrow \text{I}_2(\text{H}_2\text{N})\text{C}_6\text{H}_4\text{NO}_2$, which, diazotized and treated with KI in acid, $\rightarrow \text{I}_3\text{C}_6\text{H}_4\text{NO}_2$ and condensed with *p*- $\text{MeOC}_6\text{H}_4\text{OH} \rightarrow \text{MeOC}_6\text{H}_4\text{OC}_6\text{H}_4\text{I}_2\text{NO}_2 + \text{HI}$. In this compd. the NO_2 group is changed to CHO and then condensed with hippuric acid as follows:

$\text{RNO}_2 \xrightarrow{\text{SnCl}_2} \text{RNH}_2 \xrightarrow{\text{Diazotize}} \text{RN}_2\text{Cl} \xrightarrow{\text{CuCN}} \text{RCN} \xrightarrow{\text{Reduce}} \text{RCHNH} \xrightarrow{\text{H}_2\text{O}} \text{RCHO}$.
 $\text{MeOC}_6\text{H}_4\text{OC}_6\text{H}_4\text{I}_2\text{CH} \xrightarrow{[\text{O} + \text{H}]} \text{C}(\text{NHOCPh})\text{CO}_2\text{H} \rightarrow \text{MeOC}_6\text{H}_4\text{OC}_6\text{H}_4\text{I}_2\text{CH} \cdot \text{C}(\text{NHOCPh})\text{CO}_2\text{H}$. By boiling with HI and red P, this is changed into $\text{HOCC}_6\text{H}_4\text{OC}_6\text{H}_4\text{I}_2\text{CH}_2\text{CH}(\text{NH}_2)\text{CO}_2\text{H}$. The 1st C_6H_5 group readily takes up 2 atoms I, proving the formula for thyroxine as given above.

O. A. NELSON

Synthesis of certain iodoalkoxy acids and the mechanism of the reactions by which they are formed. ERNEST L. JACKSON AND L. PASIUT. Western Reserve Univ. *J. Am. Chem. Soc.* **50**, 2249-60 (1928).— $\text{PhCHClCHICO}_2\text{H}$ (I) reacts with MeOH, PrOH, iso-PrOH, BuOH and tert-BuOH to yield the corresponding α -iodo- β -alkoxyphenylpropionic acids. A more suitable method for the prepn. of the iodoalkoxy acids was found to be the reaction of ICl with $\text{PhCH} \cdot \text{CHCO}_2\text{H}$ and the appropriate alc. This reaction has been applied to the above alcs. By the reaction of $\text{MeCH}:\text{CHCO}_2\text{H}$, ICl and MeOH, $\text{MeCH}(\text{OMe})\text{CHICO}_2\text{H}$ is formed. The $\text{PhCH}(\text{OMe})\text{CHICO}_2\text{H}$ and the corresponding EtO derivs. were also prepd. by reaction of Cl with solns. of $\text{PhCH} \cdot \text{CHCO}_2\text{H}$ and I or an alkali chloride, in the appropriate alc. That a β -lactone is not an intermediate compd. in the formation of the iodoalkoxy acids from I is shown by the prepn. of the $\text{PhCH}(\text{OMe})\text{CHICO}_2\text{Me}$ through the reaction of MeOH with the Me ester of I. Also the iodoalkoxy acids are not formed by the elimination of HCl from I followed by the addn. of the alcs. to the double linkage thus produced, since MeOH reacts with $\text{PhCHClCMeICO}_2\text{H}$ to give the β -MeO deriv. The iodoalkoxy acids are produced either by the direct replacement of the Cl atom by the alkoxy groups, or by the disson. of ICl from the mol., followed by its reaction with the alcs. to produce the hypiodites, which then add to the double linkage of the unsatd. acid. Facts supporting the latter mechanism have been submitted. The following derivs. of $\text{PhCH}_2\text{CHICO}_2\text{H}$ were prepd.: β -MeO, m. 168-9° (*Me ester*, m. 68-9°); α -methyl- β -methoxy, m. 169-70°; β -EtO, m. 137-8°; β -PrO, m. 110-1°; β -iso-PrO, m. 113-4°; β -BuO, m. 93-4°; β -iso-BuO, m. 89-90°; β -tert-BuO, m. 113-4°; iodomethoxybutyric acid, m. 83-4°.

C. J. WEST

The effect of nitrosulfuric acid on the ethyl ester of *p*-nitrocinnamic acid. G. GUASTALLA. *Atti accad. sci. Torino* **63**, 128-32 (1928).—G. found in trying further to nitrate the Et ester of *p*-nitrocinnamic acid "A" that an oxidation product, $p\text{-O}_2\text{NC}_6\text{H}_4\text{CHO}$, was formed instead. "A" was made by the action of fuming HNO_3 on $\text{PhCH}:$

CHCO_2Et at $25-30^\circ$ and dilg. with H_2O when a mixt. of the *o*- and *p*-compds. seps. The *p*-compd. may be isolated by dissolving the product from 60 cc. of $\text{PhCH}:\text{CHCO}_2\text{Et}$ in 400 cc. EtOH , boiling and allowing to cool, giving *p*-nitrocinnamic ester "B," b. 135° . Ten g. "B" was treated with 40 g. of 92% H_2SO_4 and 20 g. of 98% HNO_3 below 25° , cooled, dild. and allowed to stand 6-7 days, when the oil solidified; it b. $50-100^\circ$, and has the odor of bitter almonds. That it was *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{CHO}$ was proved through the phenylhydrazone (N 17.3%), the α - $\text{C}_{10}\text{H}_7\text{NH}_2$ deriv. (N 9.5%), and the semicarbazone (N 26.7%).

A. W. CONTI†

New synthesis of tropic acid. MARC CHAMBER. *Compt. rend.* 186, 1630-1 (1928).—Tropic acid (I), m. 118° , is obtained in 50+ % yield from the condensation of $\text{PhCHBrCO}_2\text{Et}$, Zn dust and trioxymethylene in C_6H_6 to $\text{BrZnOCH}_2\text{CHPhCO}_2\text{Et}$. This decompd. with H_2O gives *Et tropate*, which on sapon. and crystn. from benzene and then from H_2O gives I.

PAUL J. CULHANE†

Constituents of Myoporium laetum, Forst. (The "ngaio"). III. The oxide rings of ngaione. FREDERICK HENRY McDOWALL Univ. College, London. *J. Chem. Soc.* 1928, 1324-31; cf. C. A. 21, 2263. —Ngaioi is unchanged after heating with 4 parts H_2O 10 hrs. at 250° . Catalytic reduction (Pt black) of ngaioi gives the *oxido-glycol*, $\text{C}_{15}\text{H}_{28}\text{O}(\text{OH})_2$, d_{20}^{20} 0.966, n_D^{20} 1.4664, slightly yellow oil, which gives a jade-green color with vanillin and HCl . Distn. of the product at 0.5 mm. ($160-80^\circ$) gives a compd. with d_{20}^{20} 0.9312, n_D^{20} 1.4707, H_2O being lost in the process. Tetrahydrongaione dioxide and HCl in AcOH give the compd. $\text{C}_{15}\text{H}_{28}\text{OClOAc}$, dark oil which does not solidify at -20° ; the Cl is lost by successive treatments with Zn and 80% EtOH and Zn and AcOH at 100° ; the product is a mixt. of acetates, formed by the opening of 1 oxide ring. HI and tetrahydrongaioi give a dark brown, unstable oil, $\text{C}_{15}\text{H}_{28}\text{I}_2(\text{OAc})_2$ (I); with Zn and 80% EtOH there results a compd., $\text{C}_{15}\text{H}_{28}\text{O}(\text{OAc})_2$, b_{22} $168-72^\circ$, d_{20}^{20} 0.868, n_D^{20} 1.4442, and a 2nd product, b_{22} above 172° , n_D^{20} 1.4488; hydrolysis with EtOH-KOH gives a mixt. of unsatd. hydrocarbons and monohydric alcs. One fraction b_{22} $166-73^\circ$, d_{20}^{20} 0.845, n_D^{20} 1.4524. In 1 expt., there was obtained the compd. $\text{C}_{15}\text{H}_{28}\text{O}(\text{OH})_2$, b_{22} $200-15^\circ$, n_D^{20} 1.4655. Reduction of I with Pd-HaSO_4 and H gives an I free product which, on hydrolysis, gives 2 fractions, b_{22} $155-65^\circ$ and $165-70^\circ$, a 3rd fraction, b_{22} $170-80^\circ$, d_{20}^{20} 0.904, n_D^{20} 1.4735, and a 4th, b_{22} $180-95^\circ$, d_{20}^{20} 0.924, n_D^{20} 1.4754. Reduction of I with Zn and EtOH , the resulting acetates distd. and catalytically reduced, gives the alc., $\text{C}_{15}\text{H}_{28}\text{OH}$, b_{22} $168-72^\circ$, d_{20}^{20} 0.841, n_D^{20} 1.4474; it did not absorb Br and only slowly decolorized dil. KMnO_4 in the cold. With PCl_5 followed by reduction with Zn and alc., and with Na and EtOH , there results a *paraffin*, $\text{C}_{15}\text{H}_{32}$, b_{22} $140-5^\circ$, d_{20}^{20} 0.796, n_D^{20} 1.4431; the product contained 2.3% O. Tetrahydrongaione and III in glacial AcOH give $\text{C}_{15}\text{H}_{28}\text{OI}(\text{OAc})$, yellowish oil; reduction with Zn and hydrolysis give 3 fractions, b_{22} $150-70^\circ$, $170-95^\circ$, 195° , n_D^{20} 1.4484, 1.4529, 1.4640, unsatd. and yielded semicarbazones and are therefore keto alcs. Reduction of tetrahydrongaioi with HI and red P gives a compd., $\text{C}_{15}\text{H}_{28}\text{OI}_2$ or $\text{C}_{15}\text{H}_{28}\text{OI}$; heating the alc. with HI for 20 hrs. and reduction with Zn and alc. gives a mixt. of hydrocarbon and alc., b. $220-50^\circ$. An isomer of ngaioi b_{22} $188-90^\circ$, d_{20}^{20} 1.013, n_D^{20} 1.4794. A fraction b_{22} $160-70^\circ$, d_{20}^{20} 0.9485, n_D^{20} 1.4894, analyzes for $\text{C}_{15}\text{H}_{28}\text{O}$, is probably a mixt. of mono- and dicyclic oxides. C. J. WEST

Formation of 3-*p*-menthone and 3-*p*-menthol from Δ^3 -*p*-menthene. A. KÖRZ and G. BUSCH. Univ. Göttingen. *J. prakt. Chem.* 119, 1-42 (1928).—Treatment of 8-*p*-menthanol with KHSO_4 at 200° gives Δ^3 -*p*-menthene, which when heated with Cl_2 - CCl_2H yields 4-*p*-menthanol. Consecutive treatment of Δ^3 -*p*-menthene with BzO_2H at -18° , EtONa at -10° and H_2SO_4 at -7° affords *p*-menthene oxide (I), b_{11} $70-5^\circ$, d_{14} 0.8989, $[\alpha]_D^{25}$ $45-40^\circ$, n_D^{25} 1.44809, reduced catalytically to *p*-menthane. Hot MeOH , PrOH , BuOH - and AmOH-HCl convert I into 3-*p*-menthone, while the action of HOCl is to form an impure *menthene chlorohydrin* (*chloromenthol*). It was not possible to esterify chloromenthol and oxidation expts. did not yield a ketone, thus indicating a *tert*. HO group, *i. e.*, 1 in position 4. Reduction with H and Pd black and dil. EtOH gives some 3-*p*-menthol (*H phthalate*, m. $98-100^\circ$). Most of the reduction expts. described give halogen-free products, although, in a medium of AcOH and AcONa , a Cl -contg. fraction b_{11} $72-93^\circ$ was obtained which, when treated with moist Ag_2O , yielded a product, b. 200° , with a strong menthol odor (*neomenthol*?). When chloromenthol is boiled for 3 hrs., HCl and I are produced, while heating with MeOH and PrOH and 3-*p*-menthol under pressure at $120-200^\circ$ affords 3-*p*-menthone (40-85%). Reduction of chloromenthol with Zn dust and AcOH gives 3-*p*-menthone and the action of AcCl and $\text{C}_6\text{H}_5\text{N}$ is to form *chloromenthene*, b_{11} $92-8^\circ$, d_{11} 0.9726 (89%). Δ^3 -*p*-Menthene with

PCl_5 yields a small quantity of chloromenthene, which when treated with an excess of Ag_2O or 50% KOH furnishes 3-*p*-menthone. Reduction of 2-chlorocyclohexanol with Na and EtOH gives 2-ethoxycyclohexanol (87%), b_D^{20} 82–90°, while similar treatment of chloromenthol gives *p*-menthene oxide (74%).

Optical activity and the polarity of substituent groups. VIII. Growing-chain effects and the *o*-effect in benzoic esters. H. GORDON RULE, WM. HAY and JACK PAUL. Univ. Edinburgh. *J. Chem. Soc.* 1928, 1347–61; cf. *C. A.* 22, 1342.—The rotatory powers of a no. of the homologous menthyl alkoxyacetates and menthyl H dicarboxylates have been investigated. The max. in the rotation curves of the 1 series correspond to minima in the other. This indicates that the terminal alkoxy and CO_2H groups of the growing chains produce opposite changes in rotatory power when they return to the neighborhood of the asym. atom. Similar effects are noted in the influence of substituents on the acidity of geometrically isomeric acids. Hence it is concluded that the characteristic influence of *o*-substituents in the optically active benzoic esters is propagated through space. The rotatory powers of the menthyl H dicarboxylates exhibit pronounced alternation, both in the homogeneous state and in soln. This alternation disappears in the Na salts. It is suggested that the alternation is a superimposed sec. effect due to assocn. of the ester-acids through the medium of the CO_2H group. *l*-Menthyl propoxyacetate, b_D^{20} 161°, d_4^{24} 0.9448, $[\alpha]_{5461}^{18}$ 69.44°. *Butoxyacetic acid*, b_D^{20} 115–6°, in 84% yield from 75 g. BuOH , 8 g. Na and 36 g. $\text{ClCH}_2\text{CO}_2\text{Na}$; *chloride*, b_D^{20} 108–10°; *l*-menthyl ester, b_D^{20} 172 5°, d_4^{20} 0.9397, $[\alpha]_{5461}^{20.6}$ 65.83°. *Amyloxyacetic acid*, b_D^{20} 134° (77% yield); *chloride*, b_D^{20} 103°; *l*-menthyl ester, b_D^{20} 148°, $d_4^{20.6}$ 0.9340, $[\alpha]_{5461}^{21.5}$ 61.99°. *Hexyloxyacetic acid*, b_D^{20} 143–4°; *chloride*, b_D^{20} 106–8°; *l*-menthyl ester, b_D^{20} 187°, $d_4^{24.3}$ 0.9270, $[\alpha]_{5461}^{21}$ 58.25°. *Heptyloxyacetic acid*, $m.$ 7.5–8.5°, b_D^{20} 156°; *chloride*, b_D^{20} 116°; *l*-menthyl ester, b_D^{20} 200°, d_4^{24} 0.9221, $[\alpha]_{5461}^{23}$ 55.11°. *Octyloxyacetic acid*, $m.$ 12.5–13.5°, b_D^{20} 166° (68% yield); *chloride*, b_D^{20} 125–6°; *l*-menthyl ester, b_D^{20} 183°, d_4^{28} 0.9214, $[\alpha]_{5461}^{17.8}$ 52.09°. The *l*-menthyl H esters of the satd. di- CO_2H acids were prepd. by the half hydrolysis of the di-ester by EtONa . *l*-Menthyl H glutarate, d_4^{21} 1.0318, $[\alpha]_{5461}^{21}$ 36.63°; *adipate*, d_4^{20} 1.0252, $[\alpha]_{5461}^{20}$ 33.47°; *trimellate*, d_4^{19} 1.0141, $[\alpha]_{5461}^{19}$ 31.73; *suberate*, $d_4^{19.2}$ 1.0049, $[\alpha]_{5461}^{19.2}$ 29.45; *azelate*, d_4^{20} 0.9952, $[\alpha]_{5461}^{20}$ 28.63°; *sebacate*, d_4^{20} 0.9923, $[\alpha]_{5461}^{20}$ 27.37°. Values for d and α are given for several temps. and wave lengths and in the case of the di- CO_2H esters for solns. in CHCl_3 , EtOH and C_6H_6 and for the Na salt in H_2O and EtOH .

C. J. WEST

Crystalline dihalogen derivatives of pinene. GEORGES BRUS. *Compt. rend.* 186, 87–9(1928).—From Cl and pinene, $[\alpha]_D^{25.6}$ Aschan (*C. A.* 14, 3751) obtained 2.6% of an orthorhombic bipyramidal dichloride (I), $m.$ 173–4°, $a:b:c = 0.8587:1:1.9320$. From Cl and pure pinene, $[\alpha]_D^{48}$ 1°, B. obtained 15% of a different dichloride (II), monoclinic, $m.$ 170–1°, $a:b:c = 1.337:1:1.384$. Addn. of Br to pinene yielded bornyl bromide, $m.$ 94°, liquid products and a cryst. dibromide, $\text{C}_{10}\text{H}_{16}\text{Br}_2$ (III), $m.$ 169–70°, which with Zn and EtOH yielded tricyclene. The cryst. dibromide of Pariselle (*C. A.* 15, 3287) was not obtained. III has hexagonal crystals with faces $p(001)$, $m(100)$ predominant. The clearest of numerous pyramidal faces are b^1 and b^2 . $\frac{c}{a} = 2.00$.

Angle between normals: pb^1 80.5°; pb^2 63.5°. Since III is not isomorphous with I or II, no conclusion can be drawn as to the constitution of I or II by comparison with III.

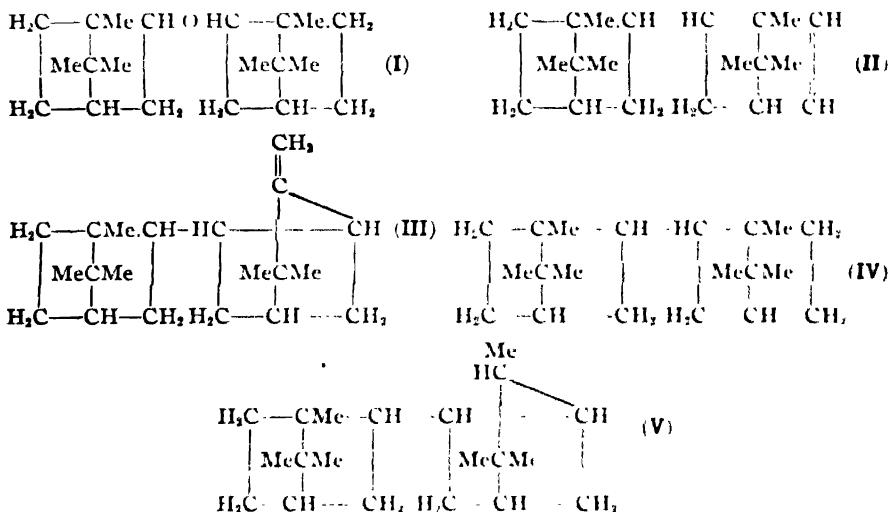

MARGARET W. MCPHERSON

The ultra-violet absorption curves of pulegone and isopulegone. JEAN SAVARD. Univ. Zurich. *Bull. soc. chim.* 43, 524–9(1928).—S. has detd. the ultra-violet absorption curves for pulegone (I) and isopulegone (II), finding I to have a max. at $1/\lambda = 41,254$ corresponding to the C:C group and at 30,664 for the C:C.CO group. II not having this latter group does not show the band, but as with I, it has a max. for the C:C at 41,237. In mixts. of I and II the band for C:C is const. and that for C:C.CO moves toward the violet and disappears at 20% of I. The curves for pure I and pure II intersect in 2 points, through which all of the curves for the mixts. also pass. The curve for pulegone from distn. of pennyroyal (III) follows that of a mixt. (IV) of 85% of I and 15% of II, of which it has been proved to consist, up to the 2nd intersection ($1/\lambda = 36,300$) but from there on going to a max. at 41,152 whereas IV goes to a max. of 41,254. If III is shaken with KOH , its absorption becomes exactly that of the mixt. IV, hence enolization is suggested to explain the variation.

A. S. CARTER

The dehydration of borneol. TETSUAKU IKEDA. *Sci. Papers Inst. Phys. Chem. Research (Tokyo)* 7, 48–61(1928).—Three hundred g. of *d*-borneol is refluxed with 150

g. ZnCl_2 in C_6H_6 during 3 hrs. The products obtained are a little camphene and 20% of resinous non-volatile matter, 60% of which crystd. out at room temp., leaving a liquid behind. The crystals, m. $43-44^\circ$, after a purification from alc. + H_2O , b_{718} 317° , b_{10} $160-2^\circ$, n_D^{45} 1.48101, $[\alpha]_D$ 65.6° , sol. in Me_2CO , Et_2O , CHCl_3 , petroleum ether, C_6H_6 , PhMe , EtOAc , less sol. in cold MeOH or EtOH , hardly sol. in cold glacial AcOH and Ac_2O , do not react with Br , dil. KMnO_4 , Na , Ac_2O . The formula I is proposed, and the compd. has been called "bornyl ether (dibornyl ether)." I gives camphor with HNO_3 , borneol with HI , bornyl acetate with Ac_2O and H_2SO_4 ; its mol wt. detn in camphor shows that 2 mols. are associated; the correct mol. wt. is obtained in boiling Et_2O . The liquid portion was a mixt of I and unsatd. hydrocarbons. Sixty g. of borneol, 60 g. of ZnCl_2 and 50 cc. of C_6H_6 were boiled for 21 hrs.; a more important quantity of camphene was obtained, together with 32 g. of a brown liquid, of which 50% b_{10} 163° (fract. 1) and 36% b_{10} $169-74^\circ$ (fract. 2). Fraction 1 had $[\alpha]_D^{21}$ 3.2° , d_4^{30} 0.9411, n_D^{30} 1.50761 and 1 double bond for $\text{C}_{20}\text{H}_{32}$. Fraction 2 had $[\alpha]_D^{21}$ 2.7° , d_4^{30} 0.9441, n_D^{30} 1.50899 and 1 double bond per $\text{C}_{20}\text{H}_{32}$. Both are diterpenes, are sol. in Et_2O , petroleum ether, little sol. in alc. and glacial AcOH or Ac_2O , absorb Br_2 , resinify with HNO_3 . Formula II or III is proposed for fraction 1. The catalytic hydrogenation of II yields a mixt of a cryst and a liquid product, both having the formula $\text{C}_{20}\text{H}_{34}$; formula IV or V is proposed for the crystals, m. $80-4^\circ$. Fraction 2 was considered as a mixt of II and some other diterpene. It is the first time that diterpenes have been obtained from borneol.

A. I. HENNE

The formation of camphene from pinene hydrochloride. TETSUAKI IKEDA. *Sci. Papers Inst. Phys. Chem. Research (Tokyo)* 7, 62-73 (1928). Pinene-HCl vapors are passed over various metallic oxides, at variable temps. and variable speeds. Camphene is formed in each case, but the majority of the oxides isomerize it and polymerize it immediately, so that the yield in camphene is small. A too high temp. and too low velocity have the same effect. A 91.2% yield of pure camphene was obtained with PbO at 250° and with BaO at 300° . The yield is somewhat less with CuO at 250° . No catalytic oxidation takes place during the reaction.

A. I. HENNE

Dynamic isomerism. XXVII. Absorption spectra of prototropic compounds. Physical properties of the stable and labile forms of benzoylcamphor. THOMAS M. LOWRY, CHARLES A. H. MACCONKEY AND HENRY BURGESS. Univ. of Cambridge. *J. Chem. Soc.* 1928, 1333-47, cf. C. A. 22, 723. Exact details are given for the prepn. of the 2 forms of benzoylcamphor; the following phys. properties are reported; the order is enol, ketone, equil. mixt., equil. proportion of enol. m. p., 89.5° , 112° , 84° , ---; α_{D}^{20} in EtOH , 331° , 152° , 258° , 10% ; in Me_2CO , 339° , 145° , 248° , 53% ; in C_6H_6 , 315° , 50° , 257° , 78% ; $\alpha_{\text{D}}^{20}/\alpha_{\text{D}}^{20}$ (rotatory dispersion), 2.393, 1.555, ---; soly. (g./100 g. soln.), EtOH at 17° , 3.37, 2.95, 5.83, 58%; Me_2CO , 17° , 19.0, 19.3, 36.4, 53%;

C_6H_6 , 17° , 37.3, 16.9, 43.1, 87% (the 3rd value in this set has for the solid phase the enol). Mol. extinction coeff. in EtOH ($M/10,000$) are given. Contrary to an earlier statement "that the 2 isomeric forms of benzoylcampbor give bands at the same wave length, but of unequal intensity," it has been found that the absorption bands are of nearly the same intensity, but differ widely in wave length. The absorption of the equil. mixt. in very dil. alc. solns. corresponds closely with that of a mixt. of 2 parts of enol and 1 part of ketone. van't Hoff's relation between the solubilities of the 2 forms and their equil. concns. has been tested for solns. in EtOH, Me_2CO and C_6H_6 and found to hold good within $\pm 8\%$. The ratio of the initial and final solubilities of the enolic form indicates that the equil. mixt. in a satd. alc. soln. contains about 58% of the enol, in close agreement with the proportion, 59%, deduced from the optical rotations of the solns.

C. J. WEST

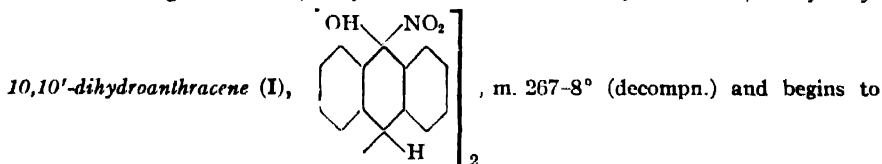

Preparation of benzophenone by means of organomagnesium derivatives. Mechanism of the reaction between the organomagnesium derivative and their carbonated derivatives. D. IVANOFF. *Compt. rend.* 186, 442-4 (1928); cf. *C. A.* 21, 3893.— Ph_2CO is prepd. in a 60% yield by treating 2 mols. of $PhMgX$ with 1 mol. of CO_2 at -20° , then shaking for 8 hrs. at 0° in a H atm. A 35% yield is obtained with $(BzO)_2Mg$ and $PhMgBr$. As it was believed that $Ph_2C(OMgX)_2$ was the intermediary product, it was treated with several acid chlorides, in order to obtain the corresponding esters $Ph_2C(OCOR)_2$ but not a trace of ester could be obtained. Conclusion: Ph_2CO is in a free state, and it has been found possible to distil it off the mixt. of $PhCO_2MgX$ and $RMgX$, before treating with H_2O . If the same mixt. is extd. in a Soxhlet app. with C_6H_6 or petroleum ether, no Ph_2CO is obtained. The intermediary compd. is $Ph_2CO \cdot xMgBr_2$. Ph_2CO is easily obtained from this compd. by treating it with an aliphatic ketone

A. L. HENNE

Photodecomposition of triphenylmethyl. SYDNEY T. BOWDEN AND WM. J. JONES. Univ. College, Cardiff. *J. Chem. Soc.* 1928, 1149-58.—This work was undertaken to ascertain whether ultra violet light is active in effecting autoxidation and reduction of Ph_3C , to det. the effective region of the visible spectrum in causing photodecompn. and to exam. the behavior of the free radical in various solvents. In ultra-violet light Ph_3C does not undergo appreciable autoxidation and reduction, either in the solid state or in soln. in C_6H_6 . The region of the visible spectrum which is most active in effecting the photodecompn. is the green-blue, viz., 5300-4000 Å. U. This corresponds to the region of greatest absorption. In yellow light Ph_3C does not undergo autoxidation and reduction. The nature of the solvent was found to exert a pronounced influence on the course of the photochem. reaction. In $PhMc$ decolorization was more rapid than in C_6H_6 ; in 1,3,5- $C_6H_3Me_3$ and m - $C_6H_4Me_2$ it was even faster; and in C_6H_4 it was most rapid of all. No perceptible loss in color was observed in SO_2 solus. The photochem. change in the solid state is of a low order.

C. J. WEST

Nitration of anthracene to bisnitrohydroanthranol (9,9'-dinitro-9,9'-dihydroxy-10,10'-dihydroanthracene). J. S. TURSKI AND A. BERLANDSTEIN. *Roczniki Chem.* 7, 457-66 (1927). —To a homogeneous mixt. of 50 g. com. pure (98%) distd. and dried anthracene in 200 g. AcOH and 80 g. Ac_2O 39 g. HNO_3 (d. 1.488) was added drop by drop during 2 hrs. at $7-8^\circ$. After 4 hrs.' stirring and 2 days' standing at room temp. the mixt. was heated to $50-5^\circ$, filtered, the deep yellow compd. sepd. from anthracene by cautious treatment with glacial AcOH, recrystd. and dried at 120° . 9,9'-Dinitro-9,9'-dihydroxy-

sublime 120° . The yield of the crude product, m. $240-50^\circ$, is 35 g. Anthraquinone, which is present in the crude product, may be easily removed with 70% H_2SO_4 . The pure product is sparingly sol. in org. solvents, sol. with decompn. in dil. hot NaOH. The Na salts are easily hydrolyzed. The NO_2 is not reduced by Na_2S or $SnCl_2-NaOH$ at $60-70^\circ$. The compd. burns explosively at high temp. or in contact with a flame. The mol. wt. (by b. p.) is 453-35. Oxidation with CrO_3 -AcOH yields anthraquinone quant. The meso-position of the NO_2 is thus established. Of the 2 formulas possible: that of a bisanthrol $C_{18}H_{16}N_2O_4$ and that of a bisanthrene $C_{18}H_{14}N_2O_4$, the latter is less probable because the compd. shows no fluorescence. A compd. $C_{18}H_{22}N_2O_{10}$, m. 290° and resembling I in all other properties, is obtained when the product of nitration is

heated to 50-5° after 3 hrs.' standing. It was given the provisional formula of *I dini-trate*.

MARY JACOBSEN

Tautomerism of brilliant cresyl blue. WALTER C. HOLMES. Dept. Agr., Washington, D. C. *J. Am. Chem. Soc.* **50**, 1989-93(1928).—A 0.1% soln. of brilliant cresyl blue in a *M*/15 acetate buffer soln. of 0.6 *M* NaCl content, having a *p*_H value of 3.42 is shaken with an equal vol. of CHCl₃; in this ext. most of the dye is present in its violet form. If the solid dye is dissolved in CHCl₃, the greater part of the dye is present in its blue form. The former tautomer is chemically inert whereas the latter is reactive. When the blue form is converted to the dye base and the dye regenerated the product is not the original dye but its mono-Me homolog. These facts are held to support H.'s hypothesis that the tautomerism is between structure of addn. product type and structure of NH₄ salt type.

C. J. WEST

New method for the preparation of phenolsulfonephthalein and bromosulfonephthalein. R. FREAS AND E. A. PROVINR. La. State College. *J. Am. Chem. Soc.* **50**, 2014-7(1928).—The procedure consists in heating 10 g. saccharin, 25 g. PhOH and 21 g. concd. H₂SO₄ at 120° for 48 hrs.; the yield is about 25%. AlCl₃, ZnCl₂, FeCl₃ and H₂PO₄ did not give as good results as H₂SO₄.

C. J. WEST

Mononitrobenzils and the heteronuclear dinitrobenzils. FREDERICK D. CHATTAWAY AND EDWARD A. COULSON. Queens College, Oxford. *J. Chem. Soc.* **1928**, 1080-8.—4-Nitrobenzil (I), m. 142°, is obtained in 42% yield by treating 100 g. benzoin in 500 cc. Ac₂O contg. 100 cc. concd. H₂SO₄ at -10° with 55 g. KNO₃ and oxidizing the semi-solid mass by boiling with 3 parts (by wt.) of concd. HNO₃; the Me₂CO mother liquors, on diln. with EtOH, give a mixt. of the 3- and 2-NO₂ derivs., from which the 3-NO₂ deriv. (II) was extd. with boiling EtOH; the mother liquors give the 2-NO₂ deriv. (III); the yields of the last two are about 1% each. Oxidation of I with CrO₃ in AcOH gives BzOH and *p*-O₂NC₆H₄CO₂H. I gives 2 isomeric phenylhydrazones, yellow, m. 200° (less sol. in alc.), and orange, m. 162°. The osazone, orange, m. 216°. 2-*p*-Nitrophenyl-3-phenylquinoxaline, m. 161°. Oxidation of II gives BzOH and *m*-O₂NC₆H₄CO₂H. Further nitration gives a mixt. of the 3,3'- and 3,2'-di-NO₂ derivs. III, on oxidation, gives BzOH and *o*-O₂NC₆H₄CO₂H. Further nitration gives 3,2'- and 2,2'-di-NO₂ derivs. Further nitration of I (13 g.) gives 7.4 g. 3,4'- and 1.7 g. 2,4'-di-NO₂ derivs. Benzoin (20 g.) in 60 cc. HNO₃ at 25-30° for 6 hrs. gives 4 g. 3,4'-, 0.5 g. 3,2'-, 0.2 g. 4,4'- and 0.5 g. 2,4'-dinitrobenzil. 3,4'-Dinitrobenzil exists in an unstable, deep yellow form, m. 127°, and a stable, pale yellow form, m. 137°; melting the unstable gives the stable form. The phenylhydrazone, orange, m. 182°; the osazone, orange-red, m. 287° (decompn.); 2-*m*-nitrophenyl-3-*p*-nitrophenylquinoxaline, m. 221°. 2,4'-Dinitrobenzil, pale yellow, m. 135°, it is phototropic and turns green in the sunlight. It yields 2 isomeric phenylhydrazones, bright yellow, m. 224° and orange, m. 201°; 2-*o*-nitrophenyl-3-*p*-nitrophenylquinoxaline, m. 186°. 2,2'-Dinitrobenzil phenylhydrazone, deep yellow, m. 199°; 2,3'-di-NO₂ deriv., deep yellow, m. 193°; 2-*m*-nitrophenyl-3-*o*-nitrophenylquinoxaline, very pale yellow, m. 168°.

C. J. WEST

Di-*tert*-butyltetraphenylethane. JAMES B. CONANT AND NEWELL M. BIGELOW. Harvard Univ. *J. Am. Chem. Soc.* **50**, 2041-9(1928).—Ph₃CClCMe₃, m. 71-2°, yields with 40% Na-Hg a brick-red Na salt, which gives with CO₂ *tert*-butyldiphenylacetic acid, m. 160° (60% yield); *p*-nitrobenzyl ester, m. 77°. Treating the Na deriv. with (Me₂CClBr), gives di-*tert*-butyltetraphenylethane, m. in the air at 40-50°, in N at 138-41°; after 12-18 hrs. in the air it becomes a sticky, brown mass. A 0.05 mol. soln. in PhBr absorbs O₂ as follows: 2 min., 70%; 5 min., 100%; 8 min., 122%; 25 min., 126%; 20 hrs., 165%. The ethane was cleaved by K-Na in Et₂O and C₆H₆ and by 40% Na-Hg in the same solvents. On heating a 0.05 mol. soln. in BzOEt, a reversible color change indicative of disson appears. On heating for a few min. in soln. at 100°, in the absence of air, it disproportionates completely. These results show that the effect of the *tert*-alkyl group in promoting the disson of the C linkage is similar to the effect of the *sec*-groups studied in the dixanthyl series. Ph₃CClCMe₃, shaken in Et₂O with 2 g. Na-K for 24 hrs., gives the isomeric ethane, m. 145°; this did not react with O₂ or with Na-K after shaking 12 hrs. in Et₂O. The isomeric chloride or Ph₃CCMeCMe₃:CH₃ yields a dark red K salt, which is not identical with the metallic deriv. above, since with CO₂ it yields an acid, C₁₈H₂₀O₂, m. 218-24° (decompn.), whose *p*-nitrobenzyl ester was an amorphous yellow powder. Decompn. of the K salt with (Me₂CClBr), gives an oil, which did not absorb O₂ in PhBr soln.; with CO₂ the acid, m. 218-24°, was obtained.

C. J. WEST

Molecular dissymmetry dependent on restriction of rotation about a single bond. Optically active benzenesulfonyl-8-nitro-1-naphthylglycine. WM. HOBSON MILLS AND KENNETH ALLAN CALDWELL ELLIOTT. Univ. of Cambridge. *J. Chem. Soc.* **1928**,

1291–1302.—If the mol. dissymmetry of certain diphenic acids is due to obstruction of the rotation of the $2C_6H_5$ nuclei of the diphenyl mol. about a common axis by substituent groups in the 6- and 6'-positions, it should be possible to obtain evidence of a similar restriction of rotation in other classes of compds. and especially among the *peri*-disubstitution derivs. of $C_{10}H_8$. This idea was tested with I. 1-Benzenesulfonylamido-8-nitronaphthalene, m. 198–9° (81% yield); the dibenzenesulfono deriv., m. 199°, is a by-product. With $BrCH_2CO_2Et$ and $EtONa$ there results 75% of *Et N-benzenesulfonyl-8-nitro-1-naphthylaminoacetate*, m. 173°; hydrolysis with dil. H_2SO_4 in $AcOH$ gives 81% of *N-benzenesulfonyl-8-nitro-1-naphthylglycine* (I), m. 214°. *Brucine l-I*, crystg. with 1 H_2O , m. 195–6°; $\alpha_{D_{40}}$ changes from -3.86° to -0.18° in 48 min. at 15.5° . The *brucine d-I*, crystg. with $3H_2O$, m. 195–6°, shows a change in $\alpha_{D_{40}}$ from 3.25° to -0.18° in 41 min. at 14.8° . *l-I* (from 0.378 g. brucine salt in $CHCl_3$) shows a change in $\alpha_{D_{40}}$ at 14.9° from -3.50° to -0.02° , while the *d-acid* at 15.3° shows a similar change from 4.19° to -0.05° , the slight final activity being due to a trace of unremoved brucine. In consequence of their ready autoracemization the brucine salts of the optically active modifications of I are evidently obtained as the result of processes of activation rather than of resolution. When equiv. quantities of brucine and *dl-I* are dissolved separately in $CHCl_3$ and the 2 solns. mixed, the initial *l*-rotation of the mixt., due to the brucine, is observed to fall gradually to an equil. value; the amt. of change depends on the temp., being greater at lower temps.; this was due to partial activation of I. *Et benzenesulfonyl-1-naphthylaminoacetate*, m. 89° (83.5% yield); *benzenesulfonyl-1-naphthylglycine*, m. 188–9° (89% yield); treatment with brucine as above gave no indication of mutarotation. C. J. WEST

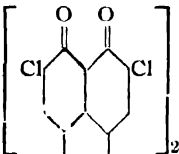

Acidic and basic catalysis of acetylation reactions. JAMES B. CONANT AND GEORGE M. BRAMANN. Harvard Univ. *J. Am. Chem. Soc.* 50, 2305–11 (1928).—Measurements are reported of the rate of acetylation of β - $C_{10}H_7OH$ by Ac_2O in glacial $AcOH$ solns. of definite H-ion activity. The rate varies nearly a million-fold and is dependent on the acidity or basicity of the medium. The max. rate is at $p_H(HOAc) -4.5$, the min. at about $p_H(HOAc) +2.0$; over this range the rate is approx. proportional to the H-ion activity. Between 2.0 and 5.0 the rate increases again, showing that the process is 1 which is subject to both acid and basic catalysis. C. J. WEST

Transformation products of anthranols and hydroxythionaphthene. F. KROLL-PFEIFFER, F. BRANSCHIED, F. THORN AND K. SCHNEIDER. Univ. Marburg. *Ann.* 462, 46–72 (1928); cf. C. A. 18, 1124.—10-Methoxy-9-anthryl Ph ketimide (I) forms a mol. complex with $PhCN$, $C_{27}H_{17}ON.HCl.PhCN$, red needles. *Ac deriv.* of I, pale yellow, m. 204–5°; HCl gives anthrone and $BzOH$. 10-Methoxy-9-anthryl *p*-tolyl ketimide, greenish yellow, m. 150° (HCl salt, yellowish red needles; *Ac deriv.*, pale yellow, m. 147°; $PhCN$ mol. compd., red); *m*-tolyl deriv., yellow, m. 127°; benzyl deriv., yellow, m. 202–3° (*Ac deriv.*, greenish yellow, m. 199–200°); *Et deriv.* HCl , pale yellow; *p*-chlorophenyl deriv. (II), pale green, m. 147–8° (*Ac deriv.*, pale yellow, m. 176–7°; $PhCN$ mol. compd., Cr_2O_3 -colored ppt.). $AcOH$ or HCl decomps. II into anthrone and *p*- $ClC_6H_4CO_2H$; cold H_2SO_4 , however, gives *p*-chlorobenzoylanthranol, pale brownish yellow, m. 206–8°; $EtOH-NaOH$ gives a deep bluish red soln., from which dil. H_2SO_4 ppt. *p*-chlorobenzoylanthranol, S-yellow. I and cold concd. H_2SO_4 give 10-hydroxy-9-anthryl Ph ketimide sulfate, red, which begins to hydrolyze during the washing with H_2O , losing N; Ac_2O gives the *di-Ac deriv.*, pale yellow, m. 206–7°. Sapon. of the ketimide gives a mixt. of benzoylanthrone, pale yellow, m. 155–7°, and benzoylanthranol, S-yellow, m. 140° (rapid heating); *Me ether*, pale green, m. 175–7° (decompn.); *Ac deriv.*, pale yellow, m. 194°. Anthranol *Me ether* (15 g.), 20 g. $AlCl_3$ and 30 cc. HCN give 15 g. 10-methoxy-9-anthracenealdehyde (III), golden, m. 165°; phenylhydrazone, yellow, m. 138–9°; oxime, yellow, m. 142–3°; the corresponding 10-*EtO deriv.*, greenish yellow, 93–4°. III with 10 parts concd. HCl yields anthrone, dianthrone, anthraquinone and HCO_2H . Anthrone (4 g.) and $CHCl_3$ with $NaOH-EtOH$ give 2.8 g. 10-hydroxyanthrylmethylene-9-anthrone (IV), dark red, and a small quantity of a compd., $C_{20}H_{16}O_3Cl_2$, pale green, m. 226–7°. *Me ether* of IV, orange, m. 221–2°. Heating IV in 5 parts $PhNO_2$ for 20 min. gives dianthrondimethemethane, m. 360°, which is reduced by Zn and $AcOH$ to IV. 3-Hydroxythionaphthene-2-aldehyde thioindogen (V) (*Ac deriv.*, yellow, m. 220°), heated with 7–8 parts $PhNO_2$, gives a bronze product, not further changed by continued heating with $PhNO_2$ and not reduced by Zn and $AcOH$. Hydroxythionaphthene (VI), HCN and HCl give 3-hydroxythionaphthene-2-aldimide, m. 145–50°, rapid heating); slowly heated to 135–55°, V is formed. 3-Methoxythionaphthene-2-aldehyde, b_p 185°, m. 84–5° (phenylhydrazone, m. 117–8°); this does not result from the methylation of the HO aldehyde, the product being 3-methoxythionaphthene-2-aldehyde-2'-thioindogen, orange, m. 218–20°. VI, $CHCl_3$ and HCl give

3-hydroxy-2,3'-dithionaphthene, m. 132-3°; soln. in H_2SO_4 , deep blue; Na salt, pale green leaflets; Me ether, m. 96-7°; 3-hydroxythionaphthenyl 2-ether, yellow, m. 198-9°.

C. J. WEST

Perylene and its derivatives. XVI. A. ZINKE, K. FUNKE AND H. IPAVIC. *Monatsh.* **48**, 741-54 (1927); cf. C. A. **20**, 1077; **21**, 1810.—Chlorination of perylene in ice-cold CCl_4 suspension affords a compd., $\text{C}_{20}\text{H}_{11}\text{Cl}_6$, m. 235° after previous darkening and sintering. Similar treatment of 3,9-dichloro- or 3,9-dibromoperylene gives, the compds. $\text{C}_{20}\text{H}_9\text{Cl}_7$ and $\text{C}_{20}\text{H}_9\text{Cl}_6\text{Br}_2$, m. 260° (decompn.) and 240° (decompn.), resp. When perylene is chlorinated in PhNO_2 at 130-40° there is formed hexachloroperylene (cf. C. A. **19**, 1568), while in presence of anhyd. AlCl_3 and PhNO_2 decachlorotetrahydroperylene, m. above 400°, is produced. This compd. is converted by fuming H_2SO_4 at 150-60° into octachlorooctahydroperylene-3,4,9,10-diquinone, m. above 400°, which when reduced with alk. $\text{Na}_2\text{S}_2\text{O}_4$ and treated with the appropriate aryl chloride affords the tetra-Bz, m. 322.5° (decompn.), and tetra-*p*-bromobenzoyle, m. 375° (decompn.), derivs. of tetrachloroperylene 3,4,9,10-diquinol. The Bz deriv is hydrolyzed and oxidized at the same time by warm concd. H_2SO_4 into tetrachloroquinone-3,4,9,10-diquinone (annexed formula), also produced from the above octachloroquinone by reduction with amalgamated Zn and HCl - AcOH . Reduction of the octachloroquinone with warm alk. $\text{Na}_2\text{S}_2\text{O}_4$ followed by atm oxidation affords a green substance (probably a quinhydrone) which when treated with cold concd. H_2SO_4 yields a dark brown substance, $\text{C}_{20}\text{H}_5\text{O}_4\text{Cl}_8$. Treatment of the octachloroquinone with boiling aniline furnishes a compd., $\text{C}_{28}\text{H}_{25}\text{O}_4\text{N}_3\text{Cl}_4$, m. 305-7° (decompn.), while distn. with Zn dust and ZnCl_2 gives perylene.

α -Furfurylamines. J. E. ZANETTI AND C. O. BECKMANN. Columbia Univ. *J. Am. Chem. Soc.* **50**, 2031-3 (1928).—The reaction of α -furfuryl bromide and $\text{EtOH}\cdot\text{NH}_3$ (satd. at 0°) for 1 week gives a mixt. of the 3 amines, sepd. by fractional distn. Difurfurylamine, b_1 102-3°; trifurfurylamine, b_1 136-8°; the colorless oils turn yellow on standing. The HCl salts, chloroplatinates, red and orange, and the chloroaurates, yellow, were prepd.

C. J. WEST

Rupture of the furan nucleus. II. R. TAKAMOTO. *J. Pharm. Soc. Japan* **48**, 366-70 (1928); cf. C. A. **21**, 3362.—Reduction of furylethylamine oxalate (m. 171-2°) which was obtained by electrolytic reduction of furylnitroethylene (C. A. **22**, 2354), with PtO_2 and H_2 gave, as a result of the rupture of the furan ring, γ -hydroxyhexylamine (I), $b_{16.3}$ 126° (yield 90.8%); chloroplatinate, m. 183-4°. I and PBr_3 gave γ -bromohexylamine-HBr (II), m. 89-90°. The free base (III) b_{22} 26-7°, b_{761} 154-5°. Picrate, m. 126-7°. Heating of III with satd. aq. KOH resulted in the closing of the 7-membered ring and gave hexamethylenimine, b_{248} 27-7.5°.

NAO UVEI

Autoxidation and the action of antioxidants. XXVII. The action of different catalysts on the autoxidation of furylethylene. CHARLES MOUREU, CHARLES DUFRAISSE AND JOHN R. JOHNSON. College of France, Paris. *Bull. soc. chim.* **43**, 586-90 (1928); cf. C. A. **21**, 2896.—The behavior of furylethylene (I) is very similar to that of styrene (II), its rate of autoxidation, however, being very much greater than that of II and even greater than that of BzH or $\text{CH}_2\text{:CHCHO}$, the O compd. so formed catalyzing polymerization. The following antioxidants are in the order of their increasing effectiveness: 0.001 β -naphthol, 0.007 phloroglucinol, 0.007 resorcinol, 0.00001 hydroquinone, 0.00035 hydroquinone, 0.007 α -naphthol, 0.0007 hydroquinone, 0.001 hydroquinone, 0.001 pyrogallol, the period of stability varying from about 1 day with 0.001 part of β -naphthol to 20 days with 0.001 part of pyrogallol. I contg. 0.001 hydroquinone became 43% nonvolatile in 3 years, whereas without the antioxidant, resinification was complete in a few days. Curves are given illustrating the oxidation rates in the presence of these and other compds.

A. S. CARTER

α -Furfuryl chloride (furyl-2-methyl chloride) and its derivatives. I. Preparation and properties of α -furfuryl chloride and a few α -furfuryl ethers. W. R. KIRNER. Rice Inst. *J. Am. Chem. Soc.* **50**, 1955-61 (1928).—Detailed directions are given for the prepn. of α -furfuryl chloride (I) from the alc., SOCl_2 and $\text{C}_4\text{H}_9\text{N}$ (63% yield); I b_{28} 49.1-9.4°, b_{28} 54.0-4.4°, d_{20}^{20} 1.1804, d_{20}^{20} 1.1783, n_D^{20} 1.4941 (Abbé). I is a relatively unstable substance but is obviously more stable than the corresponding bromide and iodide. The Cl atom possesses a high order of reactivity, comparable to that of the Cl in PhCH_2Cl . Ethers were prepd. by treating a given wt. of I in 75 cc. of dry Et_2O with 100% excess of dry KOH and 200% excess of the desired alc. Me, b_{761} 134-5°, d_4^{20} 0.1063, n_D^{20} 1.4570, 66% yield (the same order will be used below); Et, b_{770} 149.5-50.5°.

0.9844, 1.4523, 81%; Pr, b_{777} 168–70°, 0.9658, 1.4523, 79%; Bu, b_{777} 189–91°, 0.9516, 1.4522, 78%; allyl, b_{777} 173.5–4.5°, 1.0025, 1.4718, 88%; benzyl, b_1 108–9°, 1.0865, 1.5372, 83%; α -furfuryl, b_1 88–9°, 1.1405, 1.5088, 84%; cinnamyl, b_1 141–2°, 1.0802, 1.5661, 85%. C. J. WESER

Furylangelic acid. ALBERT S. CARTER. Univ. of Wisconsin. *J. Am. Chem. Soc.* **50**, 2299–305 (1928).—The so-called furylangelic acid of Baeyer (*Ber.* **10**, 1364 (1877)), which is obtained in 80% yields from furfural, PrCO_2Na and $(\text{PrCO})_2\text{O}$, m. 95.5–7° (B. gives 87–8°); O_2 gives CO_2 , EtCO_2H and possibly EtCOCO_2H , indicating that the acid is probably α -ethyl- β -furylacrylic acid; KMnO_4 oxidation gave furoic acid, AcOH and EtCO_2H . Reduction gives furylvaleric acid, b_{14} 174° (Tönnies, *Ber.* **12**, 1200 (1879)); with Br and Ag_2O this gives butyrofuronic acid, m. 149–50° (T. gives 140–2°), which should be 1-hepten-3-one-1,5-dicarboxylic acid. Reduction of this acid with HI and red P gives ethylpimelic acid and 3-heptanone-1,5-dicarboxylic acid, m. 83–4.5° (*Et ester*, b_{26} 198–200°); the latter was also obtained from furylangelic acid with HCl in EtOH, as the Et ester. C. J. WESER

Synthesis of indole derivatives. I. Synthesis of physostigmol ethyl ether. S. KIMATSU AND S. SUGASAWA. *J. Pharm. Soc. Japan* **48**, 348–55 (1928).—4- $\text{EtOC}_6\text{H}_4\text{NH}_2$ was converted into the corresponding diazonium chloride and poured into an EtOH-NaOH soln. of $\text{AcCH}_2\text{CO}_2\text{H}$ to give *Et* β -methylpyrrolacemate *p*-ethoxyphenylhydrazone (I), 4- $\text{EtOC}_6\text{H}_4\text{NHN}:\text{C}(\text{CH}_2\text{Me})\text{CO}_2\text{Et}$, orange-yellow, m. 113–4°. Boiling of I in 10% EtOH- H_2SO_4 resulted in the ring closure and gave *Et* 5-ethoxyscatole-2-carboxylate (II), m. 168–9°. The sapon. of II with 5% EtOH-NaOH gave the free acid (III), m. 184–5° (decompn.). When III was heated at 200°, CO was given off and it gave norphysostigmol *Et ether* (IV), m. 65–6°, which was purified by steam distn. and then by crystn. from EtOH. *Picrate* m. 133°. IV, Na and MeI gave physostigmol *Et ether* (V), m. 86°, also purified by steam distn. and by crystn. from EtOH. It was noted that the m. p. of IV is 20° lower than that of its *N*-Me derivs. (V). This is an unusual case in indole derivs. It was first thought that the Me group might have migrated from position 1 to 2. But the synthesis of 5-ethoxy-2,3-dimethylindole, m. 114–5°, showed this was not the case. Therefore this is one of the 2 cases where the *N*-Me compd. has a higher m. p. than the corresponding nor-compd., the other example being the 3- α -aminophenyl-1-methylindole of Kermack and Slater (*C. A.* **22**, 1355). NAO UYER

Tendency of wandering and relative firmness of union of organic radicals in the transformations of alkylated hydroxypyrazolines. K. V. AUWERS AND F. DERSCH. Univ. Marburg. *Ann.* **462**, 104–34 (1928).—This work starts from the observation of Knorr and Jochheim (*Ber.* **36**, 1275 (1903)) that by the action of concd. H_2SO_4 1-phenyl-3,4,4-trimethyl-5-hydroxypyrazoline yields 1-phenyl-3,4,5-trimethylpyrazole and extends the observations to other derivs. The following derivs. of 1-phenylpyrazol-5-one were prepd.: 3-methyl-4-propyl, m. 101–2°; 3-methyl-4-isopropyl, b_{11} 186–90°, m. 116–7°, in 6.2 g. yield from 5.7 g. $\text{AcCH}(\text{CHMe}_2)\text{CO}_2\text{Et}$ and 3.5 g. PhNHNH_2 ; 3-methyl-4-butyl, b_{12} 210°, m. 93.5–4.5°, in 9 g. yield from 18.6 g. $\text{AcCHBuCO}_2\text{Et}$ and 10 g. PhNHNH_2 ; 3,4-dimethyl-4-ethyl, b_{12} 163–5°, b_{760} 301°, m. 25.5–7.5°, in 6 g. yield from 8.6 g. $\text{AcCMeEtCO}_2\text{Et}$ and 5.4 g. PhNHNH_2 ; 3,4-dimethyl-4-propyl, b_{13} 185–9°, in 40 g. yield from 31 g. $\text{AcCMePrCO}_2\text{Et}$ and 18 g. PhNHNH_2 ; 3,4-dimethyl-4-isopropyl, m. 66–75°, from *Et methylisopropylacetacetate phenylhydrazone*, m. 111–3°; 3,4-dimethyl-4-butyl, pale yellow oil, b_{20} 205°, d_4^{20} 1.039, n_D^{20} 1.53519, n_D^{25} 1.54023, n_D^{30} 1.55339 at 16.1°, in 16 g. yield from 20 g. $\text{AcCMeBuCO}_2\text{Et}$ and 10.8 g. PhNHNH_2 ; 3,4-dimethyl-4-allyl, b_{12} 189°, $d_4^{16.7}$ 1.0708, $n_D^{16.7}$ 1.54995, n_D^{20} 1.55564, n_D^{25} 1.56978 at 16.7°; 3,4-dimethyl-4-benzyl, m. 81–2°; 3-methyl-4,4-diethyl, b_{11} 170°, m. 51–2°, in 15 g. yield from 20 g. $\text{AcCEtCO}_2\text{Et}$ and 11.6 g. PhNHNH_2 ; 3-methyl-4-ethyl-4-propyl, b_{12} 181°, in 23.5 g. yield from 25 g. $\text{AcCEtPrCO}_2\text{Et}$ and 13.5 g. PhNHNH_2 ; 3-methyl-4,4-diisopropyl, b_{13} 184° (55% yield); 3-methyl-4,4-diethyl, thick yellow oil, b_{11} 192°; 3-ethyl-4,4-dimethyl, b_{11} 177°, b_{760} 310°, in 10 g. yield from 17.2 g. *Et* α , α -dimethylpropionylacetate, b_{18} 83°, and 10.8 g. PhNHNH_2 . *Et* α -propylpropionylacetate, b_{30} 127°; α -*Et deriv.*, b_{40} 138–42°; 20.5 g. of this ester and 10 g. PhNHNH_2 give 8.5 g. of the 3,4-diethyl-4-propyl deriv., b_{40} 203–8°, $d_4^{19.5}$ 1.0352, $n_D^{19.5}$ 1.54083, n_D^{20} 1.54634, n_D^{25} 1.56018 at 19.5°. *Et* α , α -dimethylbutyrylacetate, b_{18} 99–104°; 14 g. of this ester and 8.1 g. PhNHNH_2 give 9 g. of the 3-propyl-4,4-dimethyl deriv., b_{30} 205°. *Et dibenzylacetacetate phenylhydrazone*, m. 112–3°; this could not be converted into a pyrazolone. Heating the 3-methyl-4-benzyl deriv. with PhCH_2Cl and Na gives a compd., m. 139–40°, which analyzes for the dibenzyl deriv., but its structure was not established. Reduction with Na and AmOH gives the following 1-phenyl-5-hydroxypyrazolines: 3,4-dimethyl-4-ethyl (I), m. 97–8° (0.8 g. based on 2 g. starting material); 3,4-dimethyl-4-propyl (II), m. 98° (0.7 g.);

3,4-dimethyl-4-butyl, m. 104.5-6° (1 g.); 3,4-dimethyl-4-allyl, m. 95.5-7.5°; 3,4-dimethyl-4-benzyl, m. 121°; 3-methyl-4,4-diethyl (III), m. 94-5° (0.6 g.); 3-methyl-4,4-diisopropyl (IV), m. 87-9.5° (0.4 g.); 3-ethyl-4,4-dimethyl (V), m. 78.5-9.5° (0.8 g.); 3-propyl-4,4-dimethyl (VI), m. 85-6° (0.8 g.). The following derivs. of 1-phenylpyrazole were prepd. either from the 1,3-diketone and PhNHNH₂ or by heating the corresponding pyrazolone with PBr₃ and a little yellow P: 3-methyl-4-propyl (VII), b₁₀ 155-64°; picrate, m. 111-2.5°; HgCl₂ compd., m. 180° (decompn.); HCl salt, hygroscopic, m. 84-91°; 3-methyl-4-isopropyl, b₁₀ 160-5°; picrate, light yellow, m. 100.5-1.5°; HBr salt, hygroscopic, m. 144°; 3-methyl-4-butyl, b₁₀ 170°; picrate, light yellow, m. 90-3°; 3,5-dimethyl-4-ethyl, b₁₀ 159°, m. 79-80°; picrate, m. 114.5-5°; HgCl₂ compd., m. 135-9°; 3-methyl-4,5-diethyl (VIII), b₁₀ 170°; picrate, light yellow, m. 89.5-40.5°; HgCl₂ compd., m. 142.5-3.5°; 3-methyl-4-ethyl-5-propyl, b₁₀ 175°; picrate, m. 53-65° and after standing several days or heating to 100° 84-5°; HgCl₂ compd., m. 126-7°; 3,5-dimethyl-4-propyl, b₁₀ 166°; picrate, m. 99-100°; HgCl₂ compd., m. 127.5-8.5°; 3,4-dimethyl-5-propyl, b₁₀ 190-2°, b₁₁ 160°; picrate, bright yellow, m. 75-6°; HgCl₂ compd., m. 102-4°; 3-methyl-4-propyl-5-ethyl, b₁₀ 172°; picrate, dull yellow, m. 85-7°; HgCl₂ compd., m. 136-7°; 3,5-dimethyl-4-isopropyl, b₁₀ 194°, m. 36-7°, d₄²³ 1.0208, n_D 1.55233, n_D 1.55810, n_B 1.57220 at 23.7°; picrate, citron-yellow, m. 92.5-3.5°; HgCl₂ compd., m. 128-30°; 3,5-dimethyl-4-butyl, b₁₀ 180-4°; 3,5-dimethyl-4-allyl, b₁₀ 205°, d₄²³ 1.0300, n_D 1.56332, n_H 1.56932, n_B 1.58435 at 17.4°; picrate, light yellow, m. 87-9.5°; 3,5-diethyl-4-propyl, b₁₀ 180-5°, d₄²³ 0.9930, n_D 1.53955, n_H 1.54474, n_B 1.55789 at 23.7°, from 4-propyldipropionylmethane, b₁₀ 100°, m. 160-1°; picrate, bright yellow, m. 103.5-5.5°; HgCl₂ compd., m. 102-5°. One g. III with concd. H₂SO₄ gives 0.45 g. VIII; IV gives a product from which VII was isolated as the picrate; 1 g. I gives 0.47 g. 1-phenyl-3,4-dimethyl-5-ethylpyrazole; 1 g. V gives 0.3 g. 1-phenyl-3-ethyl-4,5-dimethylpyrazole, b₁₀ 156°, b. 282° (picrate, m. 110-1°); HgCl₂ compd., m. 130.30.5°; 1-phenyl-3-methyl-4-ethyl-4-propyl-5-hydroxypyrazolone and H₂SO₄ gave in 1 expt. 1-phenyl-3-methyl-4-ethylpyrazole while in another a phenylmethyl-ethylpropylpyrazole was obtained, b. 205-7°, b₁₀ 173-5°, whose HgCl₂ compd. m. 133-5°. 1-Phenyl-3,4-diethyl 4 propyl-5-hydroxypyrazole and H₂SO₄ give IX. VI gives 1-phenyl-3-propyl-4,5-dimethylpyrazole, pale yellow, b₁₀ 180-5°, d₄²¹ 1.0120, n_D 1.54884, n_H 1.55435, n_B 1.56837 at 21.3°; picrate, light yellow, m. 72-4°; HgCl₂ compd., m. 110-1°. II gives 1-phenyl 3,4-dimethylpyrazole.

C. J. WEST

Replaceability of certain methylene groups and the relation of constitution to the stability of a C : C linkage. H. V. MOYER AND P. B. DAINS. Univ. of Kansas. *J. Am. Chem. Soc.* 50, 2293-7(1928).—4-Benzal-3-phenylisoxazolone (5 g.) and 4 g. diphenylformamidine, heated at 145° until melted and then at 120° for 45 min., give 2.5 g. 4-anilinomethylene-3-phenylisoxazolone; the piperonal, anisal-, m-nitrobenzal- and cinnamylidenephénylisoxazolones behaved similarly; furalalphenylisoxazolone gave negative results. Benzal and piperonal derivs. of 1-phenyl-3-methylpyrazolone give 4-anilinomethylenepyrazolone, m. 154°; 1,3-diphenylbenzalpyrazolone gives a similar deriv., m. 140°. 3-Hydroxy-1-phenyl-4-benzalpyrazolone, m. 275°, gives 1-phenyl-3-hydroxy-4-anilinomethylenepyrazolone, yellow, m. 272-3°; this was also obtained from the anisal deriv. 3-Phenyl- and 3-methyl-4-benzalpyrazolone do not react with diphenylformamidine. 3-Methyl-4-anilinomethylenepyrazolone, yellow, m. 204°, is obtained with difficulty. Benzal-3-phenylrhodanine, m. 192°, reacts with the formamidine to give the 5-anilinomethylene compd., m. 247°. The cinnamylidene deriv. was unaffected at temps. below 200° and above this temp., yielded only decompn. products. Benzal-di-o-tolylthiazolidone did not react after heating at 220° for 5 hrs. Benzalbenzyl cyanide, m-nitrobenzalacetylacetone and cinnamylidenacetylacetone did not react with the formamidine nor did acetyl coumarin. Benzalacetophenone gives 5% of the anil, m. 168°; p-chlorophenylimide, m. 167°; p-tolylimino deriv., m. 170°. The anil was obtained in 80% yield by heating the ketone with PhNH₂ and AcONa.

C. J. WEST

Color and chemical constitution. XXIII. Pigments of flowers. JAMES MORR. *Trans. Roy. Soc. S. Africa* 16, 121-30(1928); cf. *C. A.* 21, 2893.—M. has shown elsewhere that color is a mol. and not an at. function and that the position of an absorption band depends on the distance between 2 active positive centers in the mol.; e. g., two O, two N, an O and a N, and an O or a N and an unsatd. C atom. Eight hundred times this distance, expressed in Å. U., gives the band position. Anthocyanins show a regular gradation of shade as the anthocyanins are simplified to the parent substance by the gradual removal of hydroxyls. The greatest effects are produced by the removal of hydroxyls from positions 4' and 7. In his exptl. work M. used double oxonium chlorides with

chlorines on positions 1 and 4', although he suggests that the second HCl may be on any one of 3 pairs of unsatd. C atoms. The differences shown are claimed to be due to inactive hydroxyls, *i. e.*, those non-ionized in acid. Fifteen anthocyanidins were used and the centers of the bands range from 392 in flavylium chloride to 545 in delphinidin. M. has prepd. by Pratt and Robinson's method three new anthocyanidins without, however, giving exptl. details. *Resochrysinidin* (I), the 7-HO compd. with the band center at 435, is yellow; *protolapargonidin* (II), the 4'-HO compd., band center 438, is also yellow; *resoapigeninidin* (III), the 7,4'-(HO)₂ deriv., has its band center at 465 and is orange. The chlorides were isolated as chocolate-colored powders, insol. in ether but sol. in acid. M. believes the MeO group in other anthocyan derivs. is a mere "load" in acid soln. like the hydroxyl and has but little more effect on color. In solns. with p_H 5-6 I, II and III are apricot-orange. The central absorption is 487, 481, 489, resp. Delphinidin under these conditions gives 545 and 590. Without giving details M. indicates that he prepd. and examd. the following 2-phenylquinoline derivs.: the 7- and 4'-NH₂; 7,4'-(NH₂)₂; 5,7,4'-(NH₂)₃. The 4'-Me₂N and the 4'-HO compds. also were used. A comparison of these compds. with the corresponding O compds. indicates that the absorptions were 10 to 20% lower and that the quinoline compds. are not changed as the medium changes from acid to nearly neutral. A probable explanation of the "rise" in color in the oxonium as compared with the NH₄ type compds. is that a mutually combined configuration is possible in the former but not in the latter, *i. e.*, the pyrone O and the O of the HO group in positions 7 and 4' may be united through space or so affected that the 7- and 4'-O atoms are quinoid. Plant pigments also show a 3rd shade in definitely alk. solns. Here the hydroxyls act as positive centers and not as "loads" as they do in acid solns. The center of the absorption of II is at 538, of III at 540. Both are rose-colored. Delphinidin shows absorption centers at 690 and at 590. The compds. in this state are carbinols with a hydroxyl at 4 and ionized phenolic hydroxyls, and are not oxonium compds. Excess of alkali opens the ring at the central O and gives straight-chain compds. An elaborate table of 18 substances is given showing that gradual increases in the distance between the auxochrome and another active center in the mol., termed by M. the "hapton," here the oxonium atom, cause shifts in the center of the absorption bands, *i. e.*, give "height" to the color. Buck and Heilbron (*C. A.* 17, 2882) failed to report a strong band M. observed in the red, 675 for the 4', and 700 for the 3',4'-HO compds. of the 2-styrylbenzopyrylium series. Though having no connection with plant pigments, a table of 9 members is included showing the effect of S, O and NH in place of the ring CH:CH in otherwise similar compds.

G. ALBERT HILL

Purification of pyridine and α -picoline [2-methylpyridine] by fractional distillation. A. L. WILKIE AND B. D. SHAW. *J. Soc. Chem. Ind.* 46, 469-71T (1927).—Purification is effected by distg. the crude bases, after dehydration, through 2 fractionating columns of the Dufton type; the top portion of the 1st column and the whole of the 2nd, being encased in hot-air jackets, may be maintained at any desired temp. With 500 cc. of crude bases, after two distns., there was obtained more than 270 cc. of pure pyridine b_{760} 115.3°, d_{40}^{25} 0.9778 (cf. Heap, Jones and Speakman, *C. A.* 16, 97); the methiodide prepd. without purification from this product m. 116-7° (decompn.), while that from pyridine mixed with 5% of α -picoline softened at 100° and m. completely at 114°. α -Picoline, purified in the same manner, b_{760} 128-8.6°, d_{40}^{25} 0.9401, methiodide, m. 226-8°.

B. C. A.

Reduction of pyridine hydrochloride and pyridinium salts by means of hydrogen and platinum-oxide platinum black. XVIII. T. S. HAMILTON AND ROGER ADAMS. Univ. of Ill. *J. Am. Chem. Soc.* 50, 2260-3 (1928); cf. *C. A.* 22, 3144.—C₅H₇N in most solvents poisons Pt oxide-Pt black and no reduction takes place. C₅H₇N.HCl can be reduced readily, abs. EtOH being the best solvent, with glacial AcOH 2nd. H₂O inhibits the reduction markedly. With 0.1 mole C₅H₇N.HCl, 150 cc. solvent and 0.15 g. catalyst the reduction is complete in 6-7 hrs.; with 0.3 g. catalyst, in 1 hr.; and with 0.5 g. catalyst, in 30 min. The yield is quant. in all cases. Increase in the temp. from room to 50° decreases the time from 7 hrs. to 2 hrs. Small quantities of Fe salts and other mineral salts did not affect the reduction. Examples are given of the reduction of pyridinium and quinolinium salts. C₅H₇N gives hexahydro derivs.; C₈H₇N, tetrahydro derivs.

C. J. WESS

Dipiperidyls. C. R. SMITH. U. S. Dept. Agr. *J. Am. Chem. Soc.* 50, 1936-8 (1928).—The dipyridyls were reduced quant. to the corresponding dipiperidyls by H and Pt oxide catalysts; γ,γ -dipiperidyl, m. 172°; α,α -deriv., b. 259°; α,β -deriv., b. 269, m. 152°. β,β -deriv., b. 282°; m. 105°; β,γ -deriv., b. 270°, m. 159°; the dinitroso derivs. m. 149°, 159°, 88°, 102° and 149°; the PhNSC compds. m. 225°, 178°, 233°.

200°, 202°. The *picrate* of the β,γ -deriv. blackens at 200° but does not m. at 230°; the *chloroplatinate* turns gray at 235° but does not m. at 250°. C. J. WEST

The mercuric derivatives of isoquinoline. T. UKAI. *J. Pharm. Soc. Japan* **48**, 374-6(1928).—Isoquinoline and $\text{Hg}(\text{OAc})_2$, heated at 150-60°, gave a *compd.* $\text{C}_9\text{H}_7\text{N}\cdot\text{HgCl}$, m. 195-8°, which appears to be 8- or 5-chloromercuriisoquinoline. N. U.

Synthesis of 8-methyl-7-bromoquinoline and 8-methyl-5-bromoquinoline. T. UKAI, S. HASHIMOTO AND M. HIGASHI. *J. Pharm. Soc. Japan* **48**, 371-4(1928).—By using Skraup's synthesis on 2,6-Br(H_2N) $\text{C}_6\text{H}_3\text{Me}$ and 4,2-Br(H_2N) $\text{C}_6\text{H}_3\text{Me}$, 8-methyl-7-bromoquinoline (m. 47-8.5°; *HCl* salt, m. 223-4°; *dichromate*, decamps. 198-10°), and 8-methyl-5-bromoquinoline (m. 37-8°; *HCl* salt m. 102-3°; *dichromate*, decamps. 117-9°) were prepd. NAO UYRI

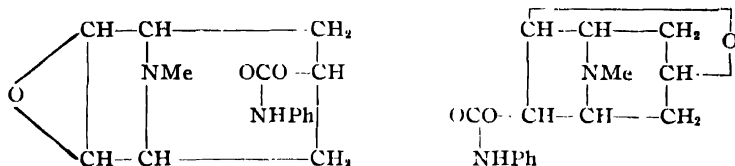

Synthetic glucosides from pyrimidine derivatives. AMANDUS HAHN AND W. LAVES. *Z. Biol.* **85**, 280-8(1926).—After 2-ethylmercapto-6-hydroxypyrimidine (12 g.) and PhNHMe (10 g.) were kept for 7 hrs. at 130-40° and the mixt. was poured into 150 cc. ether, white crystals rapidly settled out. These crystals (10 g.) were dissolved in 60 cc. boiling water, and 100 cc. of 10% AgNO_3 soln. was added; the Ag salt of 2-methyl-anilino-6-hydroxypyrimidine sepd. out immediately in amorphous flakes. To this hot mixt. 2.5% aq. NH_4OH was added slowly with stirring, thereby transforming the flakes into crystals. Further addn. gave the amorphous Ag salt of mercapto-hydroxypyrimidine (2 g.). When the filtrate was again brought to boiling and 2% NH_4OH added until neutral to litmus, the Ag salt of 2-methyl-anilino-6-hydroxypyrimidine sepd. out in amorphous form. The ppt. was pressed as dry as possible, washed in 200 cc. alc. and dried at 70°. This salt (24 g.) was dissolved in a xylene soln. of acetobromoglucose (32 g.) by heating at 155° in an oil bath. The AgBr which sepd. was filtered off and the residue treated with steam *in vacuo*. The residue after steam distn. was taken up with alc. On cooling the tetraacetyl-d-glucoside of 2-methyl-anilino-6-hydroxypyrimidine sepd. as beautiful crystals (m. 145°, *l*-rotatory, does not reduce Fehling soln.) Similar reactions gave 2-methyl-anilino-5-methyl-6-hydroxypyrimidine and 2-ethylmercapto-6-hydroxypyrimidine. F. K.

Azoxines. V. HENRI GOLDSTEIN AND ALFRED WARNÉRY. *Helv. Chim. Acta* **11**, 489-95(1928); cf. *C. A.* **22**, 1777. Turpin (*J. Chem. Soc.* **59**, 714(1891)) found that picryl chloride (I) reacts with $\alpha\text{-H}\cdot\text{N}\cdot\text{C}_6\text{H}_4\text{OH}$ in the presence of alkali to give picryl- α -aminophenol. This reaction has been applied by G. and W. to the naphthophenazoxine series. 1,2- $\text{C}_{10}\text{H}_6(\text{NH}_2)\text{OH}$ reacts with I in the presence of KOH to give 1,3-dinitro- α -naphthophenazoxime (II), m. 279°, sol. in C_6H_6 and glacial AcOH with reddish brown color, with KOH gives a violet-blue soln., H_2SO_4 blue. II on reduction with SnCl_2 and oxidation with FeCl_3 gives the base 1-amino- α -naphthophenazoxime (III). On treating the perchlorate of III with Ac_2O (anhyd. ZnCl_2 used as catalyst) the 1-acetamido- α -naphthophenazoxime is formed; the perchlorate is violet with bronze reflection. 1,3-Dinitro- β -naphthophenazoxime and its deriv. 1-amino- β -naphthophenazoxime are prepd. similarly to the α -derivs. II and III. 2,3- $\text{C}_{10}\text{H}_6(\text{NH}_2)\text{OH}$ with I gives 2',4',6'-trinitro-phenyl-2-amino-3-naphthol, m. 205°, orange; in presence of alkali, lin-1,3-dinitronaphthophenazoxime (IV), m. 313°, brick-red, with alc. KOH violet. On reduction IV gives lin-1-aminonaphthophenazoxime (V); the perchlorate in concd. H_2SO_4 gives a bluish violet changing to red, orange, and finally brownish yellow as the soln. is dild. with H_2O . On treating V with Ac_2O and ZnCl_2 , 1-acetamidonaphthophenazoxime is formed. 2,3- $\text{C}_{10}\text{H}_6(\text{NH}_2)\text{OH}$ heated with the *p*- $\text{Me}\cdot\text{C}_6\text{H}_4\text{SO}_3\text{H}$ ester of 2,4,1- $\text{C}_{10}\text{H}_6(\text{NO}_2)_3\text{OH}$ (Ullmann and Bruck, *C. A.* **3**, 435) gives [2',4'-dinitro-1'-naphthyl]-2-amino-3-naphthol, m. 205°, orange. G. and W. have been unsuccessful in their attempts to eliminate HNO_2 from this substance. HELEN COLLINS

Alkaloids of *Ouorparia rhynchophylla* Matsum. H. KONDO, T. FUKUDA AND M. TOMITA. *J. Pharm. Soc. Japan* **48**, 321-37(1928).—From the tendrils and stems of *Ouorparia rhynchophylla*, Matsum, a new alkaloid *rhynchophylline* (I) has been isolated. It has the compn. $\text{C}_{22}\text{H}_{24}\text{N}_2\text{O}_4$, m. 216°, $[\alpha]_D^{25}$ -14.7° (CHCl_3). *Chloroaurate*, m. 134°, decamps. 155°. *Chloroplatinate*, decamps. 238°. It contains 2 MeO, 1 NH group and 1 tertiary N. Sapon. of I with EtOH-KOH gives an acid, decomp. 245° (sinters at 180°). The structure of I can best be expressed by $\text{C}_{10}\text{H}_8\text{O}(\text{---CO---})\text{---OMe}_2$ ($<\text{NH}>(\text{---N}^+)$). There is a difference of 1 MeO between I and yohimbine, and a close resemblance between the 2, but I differs from the quinine alkaloids in many respects. NAO UYRI

The constitution of pseudoscorpine. MAX POLONOVSKI AND MICHEL POLONOVSKI. *Bull. soc. chim.* **43**, 590-603(1928); cf. *C. A.* **22**, 1361, 1592. The reactions of ψ -scopine (I) and its derivs. differ from those of *scopoline* (II) so greatly that they cannot be satisfied by a simple question of stereoisomerism as would exist if I were the ψ -form of II.

The evidence given in the previous papers is supplemented with exptl. details. **I** gives 2 esters with HSO_3Cl , one an ester of **II** and the other an ester of scopine. **I** gives only 1 ester, m. over 300° . **I** does not react with Na, whereas **II** yields an unstable Na deriv. When treated with PhNCO , **I** yields a phenylurethan (**III**) which is neutral, m. 229° ; *HCl* salt of **III** m. 244° ; chloroaurate of **III** slightly sol. in H_2O , m. 210° . **II** yields a phenylurethan (**IV**) which is definitely alk. This p_{H} difference requires more than stereoisomerism to be explained and the following structures are suggested for **III** and **IV**, resp.:

A. S. CARTER

Constitution of matrine. VIII. Dihydro- α -matrinidine. H. KONDO, E. OCHIAI AND T. AIHARA. *J. Pharm. Soc. Japan* **48**, 337–48 (1928); cf. *C. A.* **21**, 2135. —Catalytic reduction of α -matrinidine (**I**) with H_2 and colloidal Pd gave dihydro- α -matrinidine (**II**). Chloroaurate, decomps 202° . *HCl* salt, decolorizes at 310° . **II** and MeI gave dihydro- α -matrinidine-MeI (**III**). Chloroplatinate does not decomp. 260° . **III** and AgOH gave the methohydroxide (**IV**) of **II**, which on vacuum distn. gave des-*N*-methyl-dihydro- α -matrinidine (**V**), $\text{C}_{13}\text{H}_{24}\text{N}_2$, b_{p} $120-7^\circ$, chloroplatinate, decomps 282° , together with a weakly basic substance and a volatile base. The reduction of **V** with H_2 and Pd gave des-*N*-methyltetrahydro- α -matrinidine (**VI**), b_{p} $130-40^\circ$. MeI and **VI** gave des-*N*-methyltetrahydromethyl- α -matrinidine-MeI (**VII**). Chloroplatinate, decomps. 300° ; chloroaurate of the methochloride, m. 195° . Vacuum distn. of the methohydroxide (**VIII**) of **VI** gave besides des-*N*-dimethyltetrahydromethyl- α -matrinidine (**IX**), b_{p} $135-40^\circ$ (styphnate, softens at 60° and decomps 85° ; methochloride, decomps. 233°), Me_3N and a weakly basic compd. (**X**), $\text{C}_{12}\text{H}_{21}\text{N}$, b_{p} 110° . **IX**, Pd-C and H_2 gave des-*N*-dimethyl-hexahydromethyl- α -matrinidine (**XI**), b_{p} $115-6^\circ$, which with MeI gave the methiodide (**XII**). The chloroplatinate of the methochloride decomps. 272° . Vacuum distn. of the methohydroxide (**XIII**) of **XI** gave des-*N*-trimethylhexahydromethyl- α -matrinidine (**XIV**), $\text{C}_{16}\text{H}_{34}\text{N}_2$, b_{p} $125-31^\circ$ (chloroplatinate of the methochloride, decomps. 251°), a weakly basic substance $\text{C}_{13}\text{H}_{23}\text{N}$, b_{p} 96° , and Me_3N . Catalytic reduction of **XIV** gave des-*N*-trimethyloctahydromethyl- α -matrinidine (**XV**), b_{p} $120-30^\circ$, which with MeI gave the methiodide. Chloroplatinate of the methochloride, decomps 240° . Vacuum distn. of the methohydroxide (**XVI**) gave a base $\text{C}_{17}\text{H}_{33}\text{N}_2$, b_{p} $125-35^\circ$ (chloroplatinate of the methochloride decomps. 238°) and a weakly basic compd. $\text{C}_{13}\text{H}_{23}\text{N}$, b_{p} 95° . The above reactions are in complete harmony with the structure of **I** proposed in paper VII (*J. Pharm. Soc. Japan* **537**, 907).

NAO UYER

Alkaloids of some Indian aconites. (A. balfourii, A. deinorrhium and "chumbi aconite"). THOMAS A. HENRY AND THOMAS M. SHARP. Wellcome Chem. Res. Labs. *J. Chem. Soc.* **1928**, 1105–21; cf. *C. A.* **21**, 3623. —Both *Aconitum balfourii* and *A. deinorrhium* give pseudoaconitine (**I**), the yield from the latter being 0.4% of the air-dry roots. **I** m. 214° , $[\alpha]_{\text{D}}^{20}$ 17.06° (EtOH, c 1.18), 22.75° (CHCl_3 , c 4.76); the formula provisionally adopted is $\text{C}_{36}\text{H}_{61}\text{O}_{12}\text{N}$. *HCl* salt, m. $179-82^\circ$, $[\alpha]_{\text{D}}^{20}$ -18.1° (H_2O c 3.37); it crystals with 4 mols. H_2O but on standing in the air loses 1 H_2O . Oxalate, m. 216° ; perchlorate, m. 239° ; picrate, orange yellow, m. 196° . Hydrolysis of **I** gives pseudoaconine, $\text{C}_{28}\text{H}_{49}\text{O}_8\text{N}$, crystg. with 1 mol. Me_2CO , m. $93-4^\circ$, $[\alpha]_{\text{D}}^{20}$ 38.7° (H_2O , c 1.69); tetra-Ac deriv., m. 228° , $[\alpha]_{\text{D}}^{20}$ -8.1° (EtOH, c 0.956). Oxidation of **I** with HNO_3 (d. 1.42) for 6 hrs. at room temp. to 45° , gives a pale yellow compd. (**II**) and a bright yellow compd. (**III**). **II**, $\text{C}_{33}\text{H}_{40}\text{O}_{16}\text{N}_4$, blackens at 260° and decomps. 270° ; in the oxidation, the Ac group is unchanged but the veratroyl residue has been nitrated in position 6; the no. of MeO groups has been reduced to 5, 2 of which are in the nitroveratroyl radical; the MeN: group has been converted into a :NNO group; the remaining N is probably present as a NO₂ group, indicating the presence of a C_6H_5 ring in the nucleus. Of the 2 remaining O atoms, 1 is present as a OH group, since AcCl at 100° gives the compd. $\text{C}_{37}\text{H}_{48}\text{O}_{17}\text{N}_4$, m. $227-30^\circ$, contg. 3 Ac groups, the NO group being replaced by an Ac; hydrolysis by EtOH-KOH gives AcOH, 6-nitroveratric acid and a 3rd product, which could not be obtained cryst. Hydrolysis of **II** gives AcOH, 6-nitroveratric acid and the compd. $\text{C}_{22}\text{H}_{31}\text{O}_{10}\text{N}_3$ (**IV**), m. $165-70^\circ$ (decompn.), $[\alpha]_{\text{D}}^{20}$

30.9° (EtOH, c 0.59), with MeONa this yields the salt, $C_{22}H_{33}O_{11}N_3Na$, produced by the addn. of NaOH, which implies the presence of a lactim group in IV and also in II. While I, II and IV do not give the pyrrole pine-shaving test, the Na salt readily does so. The reaction of IV with $TiCl_3$ indicates the presence of a NO and a NO_2 group. IV and AcCl give a compd. $C_{26}H_{35}O_{12}N_3$, m. 257° (decompn.), in which the mol. of IV is probably changed, since it is not regenerated on hydrolysis. III, probably $C_{24}H_{34}O_{11}N_3$, has not been obtained definitely cryst.; it slowly decomps. at 195°; it contains a NNO group, which is removed by AcCl but a cryst. product could not be isolated. Hydrolysis of III gives AcOH, 6-nitroveratric acid and an amorphous, orange product. Oxidation of I with Cr_2O_3 gives the compd. $C_{24}H_{34}O_{11}N$, decomps. 255°, $[\alpha]_D^{20}$ 67.95° (HCl salt foams at 180°, $[\alpha]_D^{20}$ 39.5° (EtOH, c 1.006)); it rapidly dissociates on warming; *picrate*, yellow, m. 229–30°; *chloroaurate*, yellow, decomps. 185°. Hydrolysis of this oxidation product gives AcOH, veratric acid and a pink compd., m. 175–7°, which should be the compd. $C_{22}H_{33}O_7N$, though consistent analyses could not be obtained. *Chumbi aconite* roots contained 1.1% and the leaves 0.2%, of alkaloid; the alkaloid m. 203°, $[\alpha]_D$ 16.3°, analyzes for $C_{24}H_{34}O_{11}N$ and appears to be isomeric with the japaconitine of Dunstan and Read and aconitine from *A. napellus*; it resembles aconitine more than japaconitine. The HBr salt m. 175°, $[\alpha]_D$ –34.8°; the HCl salt m. 174°, $[\alpha]_D$ –35.9°; the HI salt m. 225°. Hydrolysis of the amorphous alkaloid gave evidence supporting the view that the cryst. alkaloid was aconitine.

C. J. WEST

Chemical nature of digitalic acid. P. BOURCET AND A. FOURTON. *Bull. sci. pharmacol.* 35, 345–7; *Compt. rend.* 186, 1577–8(1928).—The studies of Morin, Walz and Kolipinski are reviewed. Conclusion: The various substances called digitalic acid consist of succinic acid with more or less of impurities.

L. W. RIGGS

Nature of the hydrocarbon group of thymonucleic acid. P. THOMAS AND J. MAFREI. *XII Int. Cong. Physiol.* 1926, 159. —The 6-C sugar of thymonucleic acid is considered to be related to glucuronic acid.

B. C. A.

Some new procedures for obtaining hemin derivatives. I. O. SCHUMM. *Z. physiol. Chem.* 176, 122–6(1928).—Although hemin loses Fe and yields porphyrin when boiled with $AcCO_2H$ alone, a mixt. of $PhNH_2$ and $AcCO_2H$ or $N_2H_4 \cdot H_2O$ does not convert it into porphyrin but merely saturates the side chains. The product gives the spectrum of mesohemin. Treatment of this with $N_2H_4 \cdot AcOH$ removes the Fe with formation of mesoporphyrin. An Fe-porphyratin corresponding spectroscopically to the above intermediate may be obtained by boiling a soln. of hemin in $PhNH_2$ with AcOH and Fe powder. If hemin is boiled with pure $N_2H_4 \cdot H_2O$ such transformation does not occur. The reaction takes place when $N_2H_4 \cdot H_2O$ is added to hemin in boiling *p*-toluidine or $PhOH$, or to a boiling suspension of hemin in glycerol, glycol, $AmOH$, olive oil or liquid paraffin, or when hemin is heated with $N_2H_4 \cdot H_2O$ under pressure at 200°. Hemin undergoes a characteristic alteration when melted with pyrogallol or resorcinol. At first a product is formed which behaves spectroscopically like mesohemin. Further heating yields an Fe-porphyratin which behaves like the Fe complex of copratoporphyrin. The progress of this 2-stage reaction can be followed accurately by means of a grating spectrometer. On removal of the Fe by $N_2H_4 \cdot AcOH$ a porphyrin is then obtained which shows all the properties of copratoporphyrin. The above chem. method represents a distinct advance over the tedious and unpleasant prepn. of copratoporphyrin by means of bacterial putrefaction.

A. W. DOX

The bile acids. XX. MARTIN SCHENCK AND HENRY KIRCHHOFF. *Z. physiol. Chem.* 176, 187–99(1928); cf. C. A. 22, 2361. —The blue NO deriv., $C_{24}H_{35}N_3O_6$, prepd. by the action of HNO_3 on the diisoxime of bilianic acid, becomes colorless when treated with NaOH in excess, and from the alk. soln. a tribasic acid $C_{24}H_{35}NO_6$ (I) seps. on addn. of HCl. In the formation of this acid the 3 CO_2H groups and the lactam structure of the NO deriv. remain intact and a mere substitution of OH for NO takes place. The substance occurs in 2 isomeric modifications with different soly. and cryst. form, m. 200–5° and 260° (decompn.), resp., each of which may be converted into the other. When the dioxime of bilianic acid is treated with HNO_3 the soln. gradually becomes blue, gas is evolved, and the addn. of H_2O ppts. the reaction product which by recrystn. from 60% AcOH is obtained in light blue lustrous needles, m. 236–8° (decompn.). It contains 3 CO_2H and a NO group and has the formula $C_{24}H_{35}NO_6$. It is decolorized with loss of NO by excess of dil. NaOH, and from the alk. soln. the addn. of HCl ppts. bilianic acid, m. 276°. The dioxime yields the same tribasic acid (I) when oxidized by $KMnO_4$. Both the diisoxime and the blue NO deriv. when subjected to prolonged treatment with HNO_3 at ordinary temp. give a blue soln., which becomes green and finally yellowish brown. Addn. of H_2O then ppts. a substance $C_{24}H_{35}N_3O_{10}$, m. 212–4° (decompn.). It

is a tetrabasic acid, one of the acidic groupings probably being an OH in proximity to the NO.

A. W. DOX

The constitution of the bile acids. XIII. Catalytic reduction of some ketone acids of the bile acid group. W. BORSCHÉ AND E. FESKE. *Z. physiol. Chem.* **176**, 109-21 (1928); cf. *C. A.* **22**, 88.—The hydrogenations were performed in the Skita app., with Pt catalyst, a pressure of 3 atm. and a temp. of 90–100°. The solvent was AcOH twice distd. over KMnO_4 . Dehydrocholic acid, $\text{C}_{24}\text{H}_{44}\text{O}_8$, yielded cholic acid, $\text{C}_{24}\text{H}_{46}\text{O}_8$, which showed optical rotation identical with that of natural cholic acid. The higher rotation previously observed for the hydrogenated product is now attributed to a contamination with dihydroxyketochoholic acid, which has a *d*-rotation twice as great. Distn. of this synthetic cholic acid yielded a cholatrienic acid identical with that predp. from natural cholic acid. Hydrogenation of dehydrodesoxycholic acid, $\text{C}_{24}\text{H}_{42}\text{O}_8$, yielded desoxycholic acid, $\text{C}_{24}\text{H}_{40}\text{O}_8$, with the same rotation as the natural product, and the Me esters of the two were identical. In the same way 7,12-diketocholic acid yielded 7,12-dihydroxychoholic acid. Other reductions performed were: bilianic acid, $\text{C}_{24}\text{H}_{44}\text{O}_8$, to reductobilianic acid, $\text{C}_{24}\text{H}_{46}\text{O}_7$, m. 243° (*Me ester*, m. 135°), which on oxidation by CrO_3 in cold AcOH yielded bilibanic acid; desoxybilianic acid, $\text{C}_{24}\text{H}_{42}\text{O}_8$, to 7-hydroxylithobilianic acid, $\text{C}_{24}\text{H}_{44}\text{O}_7$ (*tri-Me ester*, m. 105°); pyrodesoxybilianic acid, $\text{C}_{23}\text{H}_{40}\text{O}_8$, to tetrahydropyrodesoxybilianic acid, $\text{C}_{23}\text{H}_{42}\text{O}_8$, m. 211–3° (*Me ester*, m. 168°), the next lower homolog of desoxycholic acid; isobilianic acid, $\text{C}_{24}\text{H}_{44}\text{O}_8$, to reductobilibanic acid, $\text{C}_{24}\text{H}_{46}\text{O}_7$. Treatment of the latter with 0.5 *N* NaOH converted it into 7,12-dihydroxylithobilianic acid, $\text{C}_{24}\text{H}_{46}\text{O}_8$, m. 162° with foaming and dehydration to the original reducto acid. Oxidation of reductoisobilibanic acid by CrO_3 in AcOH or by coned. HNO_3 removed 2 O with formation of isobilibanic acid. This analyzed low in C and its oxime and di-Me ester oxime high in N, indicating a simultaneous formation of isobilianic acid, which was difficult to remove.

Treating methane to form hydrocarbons of higher carbon content. GEORGES OLIVIER (to Soc. anon. le Petrole synthetique). U. S. 1,677,363, July 17. See *Can.* 274,783 (*C. A.* **21**, 3907).

Catalytic production of oxygenated organic compounds. I. G. FARBERMIND. A.-G. Brit. 280,522, Nov. 15, 1926. Oxides of C are passed with H over an Fe catalyst contg. small addns. of alkalis and alk. earths at a temp. below 300° (suitably about 200°) either under ordinary pressure or under reduced or slightly increased pressure. The products may comprise resinous O-contg. substances, paraffinic compds., oily liquids, alc. and an aq. soln. of org. acids.

Halogen derivatives of the benzanthrone series. OTTO BRAUNSDORF, EDUARD HOLZAPFEL and PAUL NAWIASKY (to Grasselli Dyestuff Corp.). U. S. 1,677,545, July 17. Halogen compds. are formed by reaction of a halogen (or reagent splitting off halogen) on benzanthranyl mercaptans or benzanthrone disulfides or sulfides or other thio ethers of benzanthrone, *e. g.*, alkyl or aryl thioether of the general formula X-S-Y (in which X represents a benzanthranyl residue, substituted or not, and Y represents a substituted or unsubstituted alkyl, aryl, aralkyl, or aliphatic acylidyl group, or H). Examples are given of the production of a dibromo-Bz-1,Bz-1'-benzanthranyl disulfide, a dichloro-Bz-1,Bz-1'-benzanthranyl sulfide, a dichlorodiaminobenzanthranyl sulfide, a dibromo- and monobromo-Bz-1,Bz-1'-benzanthranyl sulfide, a tribromobenzanthranyl sulfide and a dibromo-Bz-1-benzanthranythioglycolic acid.

Amino alcohols. W. MERCK, K. MERCK, L. MERCK, W. MERCK and F. MERCK (TRADING AS THE FIRM OF E. MERCK). Brit. 280,574, Nov. 10, 1926. Catalytic hydrogenation of aryl aminoalkyl ketones to the corresponding carbinols is effected by use of a Ni catalyst. Examples are given for the production of: phenyl-*N*-methylaminomethylcarbinol, phenylaminomethylcarbinol, phenyl-*N*-methylaminomethylcarbinol and racemic adrenaline.

Monoalkylaminophenols. W. TRAUBE and E. HILLRIEGEL. Brit. 280,553, Nov. 15, 1926. Thiourea compds. of aminophenols (hydroxyphenylthioureas) are desulfurized, the resulting hydroxyphenylcyanamides are alkylated, and the cyano group is split off. Examples and details are given.

Solid diazo salts of *o*-aminophenol ethers. FERDINAND KELLER and KARL SCHMITZ-SPAHN (to Grasselli Dyestuff Corp.). U. S. 1,677,558, July 17. Diazo salts are obtained by double decompn. reaction of inorg. acid diazo salt solns of *o*-aminodiphenyl ether and its unsulfonated substitution products, either with a *p*-chlorobenzenesulfonic metal salt or with free *p*-chlorobenzenesulfonic acid. The salts thus formed sep. from their solns. as cryst. whitish to yellowish or brownish ppts. and can be easily filtered and dried.

Pyridine bases. H. T. BÖHME A.-G. Brit. 280,511, Nov. 10, 1926. A mixt. of aldehydes (or aldehyde-forming substances) and NH_3 is passed under a pressure of about 50 atm. and at a temp. of about 200–400° over catalysts such as oxides or carbides of Al, Fe, Cr, W or U or oxides of rare earth metals to form pyridine bases. A product composed mainly of picolines is formed when a mixt. of AcH and NH_3 (or of C_2H_2 , H_2O vapor and NH_3) is used, with W carbide as catalyst. By use of a gaseous mixt. of CH_2O , AcH and NH_3 , pyridines and picolines are obtained.

Tetrazoles. A. BOEHRINGER (TRADING AS C. H. BOEHRINGER SOHN) Brit. 280,529, Nov. 10, 1926. Azides or free hydrazoic acid is caused to react on esters of oximes such as the sulfonic esters or the so-called Beckmann transformation products of these esters (or the components necessary to the formation of the esters), either in water or org. solvents, in neutral or slightly acid soln. or in the presence of basic substances of org. or inorg. character. Examples are given for the production of: (1) 1,5-dimethyl-1,2,3,4-tetrazole from the benzenesulfonic ester of acetoxime and Na azide; (2) 1-benzyl-5-methyltetrazole from the *p*-toluenesulfonic ester of benzyl methyl ketoxime and Na azide; (3) 1,5-diphenyltetrazole from benzophenone oxime by esterifying with aq. alc. NaOH and PhSO_2Cl , adding Na azide and warming, or by treating a mixt. of benzophenone oxime and hydrazoic acid in CHCl_3 with thionyl chloride; (4) 1,5-pentamethylenetetrazole together with ϵ -leucine lactam from cyclohexanone oxime in NaOH, PhSO_2Cl and Na azide; (5) 1,5-pentamethylenetetrazole from cyclohexanone oxime and (a) PhSO_2Cl pyridine or NaOH, and CHCl_3 followed by Na, K or NH_4 azide, (b) hydrazoic acid in C_6H_6 , PhSO_2Cl and Na azide, (c) pyridine, P oxychloride, and Na azide.

Converting cyanonaphthalenesulfonic acids into other compounds. RICHARD HERZ, FRITZ SCHULTE and WERNER ZERWECK. U. S. 1,677,086, July 10. Cyanonaphthalenesulfonic acids contg. at least 1 sulfonic group in *o* or *p* position to the cyano group are heated with alk. reagents to effect exchange of the sulfonic group for another univalent radical, e. g., Na 2-cyanonaphthalene 1-sulfonate is mixed with powd. KOH and paraffin and the mixt. is heated to about 140° with stirring and after some time the mass is cooled, diluted with water and filtered and the filtrate is acidified; a colorless compd. seps. which forms long needles when recrystd. from dil. alc. m. 179° and corresponds to the formula, $\text{C}_{10}\text{H}_7\text{OH}(1).\text{CN}(2)$. Several other examples are given of reactions of the same general type. Cf. *C. A.* 22, 2170.

Acetic acid. H. SUIDA. Brit. 280,501, Nov. 9, 1926. In processes such as described in Brit. 230,447 (*C. A.* 19, 3272) there are employed as solvents acylated or acetylated products formed from compds. such as glycol, glycerol, BuOH , heavy wood tar oils, or brown coal creosotes or other alcs. and phenols. Am butyrate, hexyl acetate and AmOAc also may be used. Acetylation of the solvent may be effected in the same app. used for the extn. and production of concd. HOAc.

Acetic acid from acetaldehyde. HOWARD W. MATHESON (to Canadian Electro Products Co., Ltd.). U. S. 1,676,454, July 10. In oxidizing AcH with O while retaining the HOAc formed in the reaction liquid, after an initial rise in temp. and pressure at the beginning of the reaction, the pressure and temp. are further increased as the acid content of the mixt. increases during the continuance of the reaction.

Nitropyridinearsonic acids. ARTHUR BINZ and CURT RATH. U. S. 1,675,402, July 3. See Brit. 275,590 (*C. A.* 22, 2244).

Aryl-substituted quinoline-4-carboxylic acids. ALFRED HAUSMANN (to C. H.

Boehringer Sohn Chemische Fabrik). U. S. 1,676,862, July 10. In producing products of quinoline-4-carboxylic acid aryl-substituted in the second position, 1 mol. of pyrrolic acid is caused to react, in the presence of a solvent such as alc. with more than 1.5 mols. of a condensation product from an aromatic amine such as PhNH_2 and an aromatic aldehyde such as BzH .

2-Hydroxynaphthalene-3-monosulfo-6-carboxylic acid. FRIEDRICH KRECKE (to Grasselli Dyestuff Corp.). U. S. 1,676,698, July 10. This compd. is produced by heating 2-hydroxynaphthalene-6-carboxylic acid with H_2SO_4 or oleum and dilg. with water. It is sol. in hot water, difficultly sol. in dil. acids, its di-Na salt crystallizes in compact needles, and a blue fluorescence is shown by its solns. with dil. alkali carbonate and by its difficultly sol. neutral Ca salt.

1-Methoxynaphthalene-2-carboxamide. RICHARD HERZ, FRITZ SCHULTE and WERNER ZERWECK (to Grasselli Dyestuff Corp.). U. S. 1,676,692, July 10. This compd. is produced by heating KOH, MeOH and Na 2-cyanonaphthalene-1-sulfonate. It is a colorless powder, crystg. from water or dil. alc. as long colorless needles, m. $156-7^\circ$, insol. in alkalies.

Valerylresorcinol. ALFRED R. L. DOHME (to Sharp & Dohme, Inc.). U. S. 1,677,116, July 10. This compd., $\text{C}_6\text{H}_3(\text{OH})_2\text{CO}\cdot\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$, is made by reaction of valeric acid on resorcinol in the presence of ZnCl_2 . It is a cryst. compd., m. $58-60^\circ$ and b_{6-7} $190-2^\circ$.

Isobutyrylresorcinol. ALFRED R. L. DOHME (to Sharp & Dohme, Inc.). U. S. 1,677,117, July 10. This compd., $\text{C}_6\text{H}_3(\text{OH})_2\text{CO}\cdot\text{CH}(\text{CH}_3)_2$, is made by reaction of isobutyric acid on resorcinol in the presence of ZnCl_2 . It is a cryst. solid, m. $67-68.5^\circ$ and b_{6-7} $173-5^\circ$.

Chlorinating methane by use of antimony pentachloride. ERICH KRAUSE (to Holzverkohlungs-Industrie A.-G.). U. S. 1,677,831, July 17. Reaction of CH_4 with SbCl_5 at a temp. of about 300° forms CH_3Cl and other products.

Paraformaldehyde. KARL SATOR and WILHELM PFANNMÜLLER (to I. G. Farbenind. A.-G.). U. S. 1,677,730, July 17. In producing polymerized CH_2O , water is removed from a gas mixt. contg. CH_2O and water, e. g., by cooling, and the solid product is sepd. from the remaining gases. Cf. C. A. 22, 1163.

Polymerized styrene, etc. IVAN OSTROMUISLENSKII (to Naugatuck Chemical Co.). U. S. 1,676,281, July 10. Styrene or similar compds. such as *o*- and *p*-methylstyrene or sym. *m,m*-dimethylstyrene are emulsified, e. g., with aq. NH_3 and oleic acid, and polymerization may then be effected by heating, e. g., at 140° for 12-24 hrs. MeOH may be used to ppt. the product, and the latter may be used for making various molded articles and may be mixed with pigments or other materials.

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

Transport numbers of proteins. DAVID M. GREENBERG. Univ. of California. *Trans. Am. Electrochem. Soc.* (preprint), Sept., 1928.—Transport numbers for casein and the A, B and C fibrins dissolved in 0.1 *N* acids or bases indicate that definite compds. are formed between the acid or base and the protein. The electrode deposit is found to be (1) proportional to the current, and (2) inversely proportional to the amount of acid or base combined with the protein or to the charge carried by the protein. The transport numbers vary inversely as the mobility of the cation. These results indicate a salt-like behavior rather than the current colloidal theory of protein behavior. Complex formation between the protein and the hydroxides of the alkaline earth series is indicated by the exptl. evidence. C. J. BROCKMAN

Biochemical effect of high-frequency currents on rabbits. ALBERTO SCALA AND NICOLA SETTE. Univ. Rome. *Ann. Igiene* 36, 642-58 (1926); *Chem. Zentr.* 1927, I, 313.—Rabbits subjected to currents of high frequency immediately or very shortly excrete urine, the alk. and Ca content of which are abnormally low. The current hydrolyzes the colloidal complexes of all tissues, with liberation of acids, insofar as the complexes are not already injured through other agencies. As a result, the tissues become more strongly hydrophilic and the colloid components tend to form solns. or dispersions, Ca exercising an inhibitory action in this respect. In summer, bases in-

stead of acids are liberated, which render the organism alk. in reaction, because the high frequency hydrolyzes the second zone of electropositive ions of the tissue colloids when the first zone of electronegative ions is exhausted through the effect of high temps. The high frequency has the same influence as x-rays on rabbits, though the magnitude of the effect is smaller. The increased hydrolytic activity results in ammoniuria, and the disturbance of the equil. of the colloids of the kidney tissues results in albuminuria.

C. C. DAVIS

The fixation of nitrogen in the synthesis of protein in nature, and biological interest in the physiological oxidation reactions and their reversibility. F. KNOOP. Univ. of Freiburg. *Munch. med. Wochschr.* 73, 2151-3(1926); *Chem. Zentr.* 1927, I, 1027.—In 1910 K. succeeded, with the aid of nascent H, in forming small quantities of phenylalanine from the corresponding ketonic acid. With the aid of Pt and Pd as catalysts, K. has now succeeded in isolating up to 70% amino acids of the most varied types at room temp. and atm. pressure, i. e., under conditions existing in the living cell. Ketonic acids fix NH_3 with addn. of 1 mol. of H_2 much more easily than does H alone, with the formation of hydroxy acids. Accordingly where ketonic acids and NH_3 meet in the cell under conditions favorable to hydrogenation, amino acids form very readily. Amino acids were also isolated from the products of the action of cysteine on ketonic acids and NH_3 .

C. C. DAVIS

The enzyme index of catalase and protease during digestion. E.^o IVANIZKIJ-VASILENKO. *Uchenye zapiski saratovskogo gosudarstvennogo univ.* 3, 301-20(1925); *Chem. Zentr.* 1927, I, 1180.—The variations of the catalase index are sometimes independent of the absorption of nutrients. A meal of meat or of milk increases the index only after 2 hrs. After the removal of the pancreas, the index diminishes (expts. on cats).

C. C. DAVIS

Catalase, anticalase and phyllocatalase in animal tissue under various physiological and pathological conditions. I. Determination of catalase in blood. E. GAGARINA AND W. JANKOWSKI. *Zhurnal ekspl. Biol. Med.* 1926, 33-51; *Chem. Zentr.* 1927, I, 1193; cf. C. A. 21, 3636.—Besides catalase, anticalase and phyllocatalase are also present in the blood, which disturb the detn. of catalase in the blood. Expts. by G. and J. were directed toward eliminating the disturbing factors. Maintaining blood dild. from 1:25 to 1:50 for 30 min. in a thermostat at 37° with and without the addn. of EtOH had no influence on the action of the catalase. On the other hand the latter action diminished at dilns of 1:500 and 1:1000. The diminution can be prevented by EtOH even at dilns of 1:50,000. Subsequent addn. of EtOH activated again a greater part of the inactivated catalase, but not the total quantity. C. C. D.

Vital force. P. C. E. MEERTM TERWOGT. *Chem. Weekblad* 25, 306-7(1928).—A philosophical discussion suggested by the centenary of Wohler's synthesis of urea. The statement frequently met with in textbooks that this great discovery has resulted in banishing the concept of vital force from chemistry is true only insofar as mere chem. substances are concerned. Schopenhauer's view that the phys. and chem. forces at work in the animal organism are interrelated and directed by a vital force necessary for the existence of a purposive organism still holds. The creation of an organism by the chemist, although conceivable, is a vision belonging to the category of perpetual motion and squaring the circle.

A. W. DOX

Comparative investigations on light absorption in the ultra-violet by α -amino acids. EMIL ABDERHALDEN AND ERNST ROSSNER. *Z. physiol. Chem.* 176, 249-57(1928).—Detns. were made of the ultra-violet absorption of amino acids, mixts. of amino acids, mixts. of amino acids and their corresponding anhydrides, and hydroxyamino acids for the purpose of ascertaining any noteworthy variations. The results were for the greater part negative. Similar curves but at slightly different locations were obtained for: proline and hydroxyproline, and for phenylalanine, tyrosine and dihydroxyphenylalanine. With mixts. of amino acids the curves plotted between concns. of the components and A. U. of max. absorption showed no irregularity, while with mixts. of amino acids and their anhydrides the curves assumed a somewhat logarithmic form.

Cozymase and the activation of fresh yeast fermentation by yeast extract. KARL MYRBÄCK AND HANS V. EULER. *Z. physiol. Chem.* 176, 258-68(1928).—The substance which increases the fermentation velocity of living yeast without increasing the no. of cells, and which is designated as "Factor Z," is essentially different from cozymase. It is readily sol. in 94% EtOH, is not pptd. by $\text{Ba}(\text{OH})_2$ or $\text{Pb}(\text{OAc})_2$, but pptd. by $\text{Pb}(\text{OAc})_2 + \text{NaOH}$, is diffusible through collodion, and is not affected by autolysis. While a quantity of boiled yeast ext. contg. 2 cozymase units accelerates the fermentation of fresh yeast more than 100%, purified cozymase of 30 units is without effect.

Conversely, solns. which contain no cozymase activate fresh yeast. Kostychev's assumption that added cozymase activates fresh yeast fermentation is erroneous and is therefore not relevant to the discussion of the question whether the fermentation by dried yeast is due to the presence of living cells.

The chromoproteins. The acid-binding power of globin. N. ISHIYAMA. *Z. physiol. Chem.* 176, 294-300(1928).—The chromoproteins are salts in which basic proteins are combined with acidic prosthetic groups. Thus hemoglobin consists of approx. 96% globin and 4% hemochromogen. It is readily split into these components by addn. of acid, but the free hemochromogen is so easily altered that when recombination occurs the resulting ppt. is a salt of hematin with globin. The globin-HCl salt obtained by cleavage of hemoglobin has an av. HCl content of 5.07%. If combined in the same mol. proportions, the H_2PO_4 content of globin phosphate should be 12.55%, which is in agreement with the values 11.80 and 12.07 actually found. Mineral acids, therefore, combine with globin in stoichiometric proportions. For org. acids, however, the binding power is lower. Eosin forms a salt with globin and this contained 32.10 and 32.59% eosin instead of the calcd. 37.98% on the basis of I content. Taurine, a still weaker acid, forms a globin salt with 1.16% taurine instead of 15.59%. This diminished binding power of globin for weak acids explains the low hemochromogen content of hemoglobin.

Specificity of animal proteases. XIV. Comparison of the activation performance of enterokinase of various origin. ERNST WALDSCHMIDT-LEITZ AND OSAMU SHINODA. *Z. physiol. Chem.* 176, 301-13(1928).—Kinase preps. from the intestinal mucosa of all the animals tested (pig, horse, steer, sheep, dog, cat, rabbit, goat, ape and sea lion) activate trypsin from pig pancreas. Noteworthy differences exist only in the activation performance of the individual kinases toward sea-lion trypsin, the activity of which is increased to a much greater extent by kinase from dog, rabbit and ape than by that from pig and steer. The differences in velocity of hydrolysis, which are considerable, are shown in the cleavage of both casein and clupein. One might be inclined to infer an identity of the various kinases, except for the non-equivalence of the systems: sea-lion trypsin-pig kinase and sea-lion trypsin-steer kinase, on the one hand, and sea-lion trypsin-dog, rabbit and ape kinase on the other hand. The sea lion represents a different order of mammals and before a sp. difference in its kinase can be considered established, other members of this order must be examd.

A. W. Dox

Methylglyoxalase and cozymase. ALFRED GOTTSCHALK. *Z. physiol. Chem.* 176, 314-6(1928).—Dried bottom yeast which has been freed from cozymase by washing is no longer capable of converting $AcCHO$ into lactic acid. With a very low content of cozymase the dried yeast has only a slight action on $AcCHO$. The methylglyoxalase activity of yeast is, therefore, dependent on the presence of cozymase. The three known components of the yzyme complex, the activity of which requires the complementary action of cozymase, are now phosphatase, aldehyde-mutase or reductase and methylglyoxalase.

The iron porphyratins. The reversible side-chain reaction of the hematins and the behavior of hemin and the hematins toward acids. Preparation of hemateric acid from hemin and organic acids. O. SCHUMM AND E. MERTENS. *Z. physiol. Chem.* 177, 15-23(1928); cf. *C. A.* 22, 245.—The reversible side-chain reaction of α -hematin (hematin \rightarrow dimethoxyhematin di-Me ester \rightarrow hematoporphyrin \rightarrow hemateric acid \rightarrow hemin) has now been performed also with β -hematin and hemin. The conversion of dimethoxyhematin di-Me ester, after removal of Fe, into hemateric acid (3rd stage) may be effected either by boiling HCl or more rapidly by $AcOH$ contg. a little H_2SO_4 . The view previously expressed, on the basis of spectrochem. analysis, that the unsatd. side chain of hemin becomes only partially satd. after prolonged boiling with $MeOH$ contg. 1% HCl is now confirmed by elementary analysis. The Fe complex obtained by this procedure is the tetra-Me deriv. of the Fe complex of Nencki's hematoporphyrin, now designated dimethoxyhematin di-Me ester. The reaction circle can be shortened to 2 stages by boiling this product (1st stage) several hrs. with $AcOH$, whereby reversion to the hematin stage occurs. By boiling with HCl this di-MeO deriv. and the Fe complex of Nencki's hematoporphyrin are converted into a hematin-like substance which differs from true hematin in its greater resistance to $N_2H_4 \cdot AcOH$. The same or an analogous substance is formed from hematin by boiling HCl, but from hemin only by prolonged boiling. In the action of boiling acids on hemin great differences are shown not only between 25% H_2SO_4 and HCl, but also between various org. acids. $AcOH$, 10% oxalic, 70% lactic and $AcCO_2H$ manifest an almost sp. behavior in each

AcOH maintains the original structure, oxalic forms 2 distinct porphyrins one of which is hemateric acid, lactic forms predominantly hemateric acid, while pyruvic easily splits off Fe from pure hemin with formation of hemateric acid but from hemin dissolved in PhNH₂ no Fe is split off although the substance is definitely altered. Malonic, succinic, tartaric and citric acids in 10% soln. do not convert hemin or hematin into a porphyrin or cause otherwise any noteworthy change. The hematins are distinguished to a certain extent by their varying resistance to boiling HCl. For the prepn. of hemateric acid in good yield the treatment of hemin with AcCO₂H is recommended.

Glycocyclamase. JUNJI KARASHIMA. *Z. physiol. Chem.* **177**, 42 (1928).—Beef liver contains an enzyme which hydrolyzes glycoylamine into glycine and urea. The enzyme was not found in the kidney, pancreas, spleen or lung. It is possible that glycoylamine is an intermediate product of arginine metabolism. Its homolog, guanidinobutyric acid, is known to undergo a similar enzymic cleavage into urea and aminobutyric acid, and both of these guanidino acids might be formed in successive stages in the oxidation of arginine. The enzyme was not found in chicken liver or kidney. A. W. D.

Odor and constitution among the mustard oils. G. M. Dwyson. *Perfumery Essent. Oil Record* **19**, 88-91 (1928); cf. *C. A.* **22**, 1436.—The expts. previously described have now been extended to an examn. of the influence of halogen substituents on the odor of mustard oils. In order suitably to correlate the results obtained, it is necessary to adopt some theory of odor perception. The many exptl. findings on the phenomena of odor lead definitely to the conclusion that direct contact of the odorous substance with the processes connected with odor perception is necessary before perception can take place. The relation of odor intensity to vapor pressure at high diln. has been established, and in addn. it is known that all odorous substances exert a definite vapor pressure, while apparently odorless substances may be caused to excite the sensation of odor by the simple method of irrigating the olfactory processes with their isotonic salt solutions. Odor intensity then depends on the vapor pressure at lower dilns., the intensity increasing as the vapor pressure increases until a point is reached beyond which the increase of concn. produces little or no increase in the strength of perception of the odor, i. e., the olfactory satn. point. The mere existence of such a point indicates that such a process of odor perception must be bound up with actual mol. contact rather than with other phenomena. If odor perception is due to the intramol. vibrations of the mols. concerned, then there is a very sound parallel between the 3 senses of sight, hearing and smell, and one is able to correlate differences of odor with variations in mol. vibration. Variety in smell may, therefore, be due to 2 causes. In the first place it may be due to simple variations in olfactory frequency, or it may be due to the superposition of 2 or more olfactory frequencies leading to the receipt by the brain of a multiple effect—a process analogous in many ways to the perception of a musical concord or discord or of a mixed tint. It seems not improbable then that odor is as capable of fundamental measurement as any other property, and that when it is possible to measure the intramol. vibrations assocd. with a particular mol., then one can define mathematically its odor. In applying these considerations to the question of mustard oils and their odors it is essential that the idea of surface action be kept to the front, since it is capable of furnishing the reason for the apparently large variations of odor caused by comparatively slight constitutional changes. With *p*-chloro-, *p*-bromo- and *p*-iodo-phenyl mustard oils there is practically no difference between their odors, each having a powerful anise odor which appears to be sweeter with the Br compd. than with the Cl compd., the I compd. having the softest odor of the 3. With the *m*-, and *o*-substituted phenyl mustard oils a considerable difference is observed between the various halogen derivs. Thus, the *o*-Cl compd. has a very keen "mustard oil" odor, which is less apparent with the corresponding Br compd., and almost non-existent with the I compd. A similar set of relations is apparent with the *m*-compds. Touching the relation of orientation and odor in the monohalogen-substituted phenyl mustard oils it appears there are at least 2 fundamental intramol. vibrations assocd. with these oils, one with the pungent or "true mustard oil" odor (primary osmic frequency) and the 2nd with the sweeter or anise odor (secondary osmic frequency). In phenyl mustard oil the primary osmic frequency almost completely overwhelms the secondary, but it appears that any substituent in the *p*-position (Me, Cl, Br, I, CN, OMe, OEt, COOEt and COMe) have been successfully tried) either completely suppresses the primary osmic frequency or else alters it to such an extent that it is shifted out of the limits of odor perception. Interesting light is thrown on this matter when it is considered from the standpoint of chem. reactivity of the NCS group. The presence of a halogen substituent invariably accelerates the reaction between the mustard oil and alc., but this

acceleration is by no means produced when Me or MeO groups replace the halogen. This points to the fact that amplitude of the intramol. vibrations is connected with the reactivity, which is not greatly influenced by their frequency, and that in the mustard oils the *p*-substituent does not lead to complete suppression of the primary olfactory frequency, but merely shifts it out of the limits of odor perception. The application of the above theory to the presence of 2 or more halogen atoms in the same Ph residue simplifies any consideration of their behavior. On the assumptions that a *p*-substituent shifts the primary olfactory frequency outside the limit of odor perception, and does not appreciably affect the secondary osinic frequency; that an *o*-substituent tends to act as the *p*-group with respect to the shift in olfactory frequency, but to a smaller extent; and finally that a *m*-group tends to produce a shift in primary olfactory frequency in an opposite direction to that produced by an *o*- or *p*-group, one should predict that both dichlorophenyl mustard oils in which a *p*-group is present would retain their anise odor, but that the 3,4-deriv. would possess a more pungent odor than that of the corresponding 2,4-compd., that the 3,5-dichloro compd. would be wholly pungent, the 2,6-deriv. wholly sweet in odor, and the 2 remaining isomers (2,5- and 2,3-dichloro-derivs. of an equally pungent odor) both more pungent than the 2,4-deriv., but less so than the 3,5-compd. Five of these isomers have now been prepd. and examd. in a high state of purity, but so far the 2,6-compd. has not been obtained. The other 5 dichlorophenyl mustard oils fulfill the predicted odors with the possible exception of the 3,5-derivs. which are less pungent than the simple *m*-chlorophenyl mustard oil. In this case, however, the apparent difference is in all probability due to differences in volatility resulting in a difference in intensity rather than in nature. Investigation of the F compds. is at present under way.

W. O. E.

Odor and constitution among the mustard oils. G. MALCOLM DYSON. *Perfumery Essent. Oil Record* 19, 171-4(1928). cf. preceding abstract.—The author's previous work has now been extended to include compds. contg. both halogen and Me groups together. The conclusions which may be drawn from the investigation are: (1) The "pungent" and "anise" aspects of the olfactory sensation are probably due to sep. frequencies, and that *m*-substitution is more conducive to pungency than is *p*-substitution, which in all cases leads to the appearance of the "anise" note. (2) It seems clear that the chloro group is a more powerful alterant of olfactory frequency than the Me group, since in 4-methyl-3-chlorophenylthiocarbimide the pungent note almost overwhelms the anise odor, a state of things which is reversed in 3-methyl-4-chlorophenylthiocarbimide. The results of the present study uphold the generalization that the effect of the substituent groups upon the odor of aromatic mustard oils is governed by 3 empirical rules, as follows: (a) The effect is dependent on the orientation of the groups, *p*-substituents causing a marked anise note, *m*-groups contributing pungency, and *o*-groups having their effect mainly on the floral character of the odor. (b) The nature of the odor is dependent more upon orientation than upon the nature of the substituent group. (c) Where the Me and chloro groups occur together in the same mustard oil, the effect of the chloro group is invariably more strongly marked than that of the Me group.

I. The accurate measurement of the proportion of corpuscles and serum in blood.

II. The volume of red blood corpuscles in venous and oxygenated blood and after exposure to various saturations of carbon dioxide. F. H. SMIRK. *Brit. J. Exptl. Path.* 9, 81-9(1928).—By centrifuging small quantities of blood which have been drawn into capillary U-tubes between layers of paraffin an accurate microhemocrit method was developed in which the tension of the blood gases is unchanged. If blood is allowed to stand in capillary tubes of Jena and ordinary glass for 2 or more hrs. the percentage vol. of corpuscles diminishes slightly in both types of glass, but more so in ordinary glass. This difference is not more than 2% after 5 hrs.' exposure. It is suggested that this is due to the alkali of the glass causing an increase in p_H of the blood. This factor would be due to the enormous increase in glass surface relative to the vol. of blood. Oxygenation of venous blood causes a slight diminution in the percentage vol. of corpuscles. An av. of 55 hemocrit observations shows a variation of rather more than 1% of the vol. of corpuscles. Exposure of human blood to 50% CO_2 caused an increase of 11% in the vol. of corpuscles, which was maintained within 2% after 15 hrs.' exposure. 100% CO_2 produced a change of about 17% in the vol. of corpuscles, which was maintained within 3% after 21 hrs.' exposure. Complete restoration of the corpuscular vol. is obtained if the blood is removed from the CO_2 and desaturated. H. F. H.

Dehydrogenation of succinic acid. AMANDUS HAHN and W. HAARMANN. *Z. Biol.* 87, 107-14(1928); cf. *C. A.* 22, 1601 —When succinic acid is dehydrogenated by muscle tissue in a vacuum in the presence of methylene blue, the chief product is fumaric acid. This is converted to malic acid by hydrolysis. Further dehydrogenation of malic acid yields small quantities of other products, not yet identified. It was found possible to det. fumaric acid in the presence of malic and succinic acids. F. K.

The relation between viscosity and electrolytic dissociation in colloidal solutions. The behavior of gelatin hydrosols before and after treatment with proteolytic agents. S. VISCO. *Arch. sci. biol.* 8, 471-9(1926).—If, according to Loeb, it is true that the influence of electrolytes is a function of the micelles of solid gel present in protein solns., then by varying the micelles, the influence of the electrolytes should also vary between a max. and a min. If the micelles are present, the addn. of trypsin should reduce them into less complex substances down to amino acids. V. tried to prove the assumption by the following exptl. method: 30 g. gelatin was melted in 500 cc H_2O , a definite quantity of HCl was added and the vol. brought to 1 l. The flask was placed in the incubator for 1 hr. and the p_H detd. To 500 cc. of it 1 g. trypsin was added and the flask placed in the incubator together with the 500 cc trypsin-free gelatin as a control. After 1 hr. the flasks were placed in an Arnold sterilizer for 30 min. to destroy the enzyme and to sterilize the solns. after which they were again incubated. The p_H of both solns. was 4.6. Thirty-cc. samples were removed from each flask and placed in smaller flasks. Varying amts. of HCl were added to obtain different p_H . The flasks were incubated for 60 min. and the η detd. The results are given in the form of 6 graphs, showing the relation between η and p_H , when trypsin acted on the gelatin for 1, 2, 3, 4 $\frac{1}{2}$, 6 and 10 hrs. Beginning at the isoelec. point, the η reaches a max. at p_H 2.8, beyond which it diminishes again. The η of isoelec. gelation subjected to the prolonged action of trypsin is not modified by the action of HCl even if the p_H varies from 4.6 to 2.8. The influence of p_H on η is inversely proportional to the time trypsin acts. The data favor Loeb's hypothesis, namely, that micelles of solid gel are present and these play an important part in explaining the influence of electrolytes on the physicochem. properties of certain protein solns. PETER MASUCCI

Preliminary experiments on the nature and mechanism of formation of metal proteinates. A. BENEDICENTI and G. B. BONINO. *Arch. sci. biol.* 8, 241-7(1926); cf. following abstract.—The investigation aimed to develop exptl. methods for the detn. under various conditions and for various metals of the type of mechanism governing the formation of metal-protein compds. Two electrode tubes were connected by means of a capillary syphon with a glass stopcock. Into one tube was placed a Co-protein soln. and into the other the untreated protein soln. A Co electrode was immersed in the Co-protein soln. and a Pt electrode in the other. The p. d. between the two electrodes is expressed by the simplified formula: $E = (RT/F)(\frac{1}{2} \log [Co^{++}] - \text{Const.})$ The ratio E/I depends on the concn. of Co^{++} ions in the metal-protein soln. The relation of E to temp. was detd. The two electrodes were brought to the same temp. and by means of a galvanometer used as a voltmeter and with sufficient resistance interposed, the p. d. was measured. Graphs are given showing the relation of E to temp. for egg albumin and beef serum undild. and dild. and at various p_H . All the curves show a max. p. d. which coincides with the temp. at which protein is coagulated by heat. In most curves there is an inflection at 35-40°. PETER MASUCCI

Studies on metal proteins. I. G. B. BONINO AND M. BOTTINI. *Arch. sci. biol.* 8, 248-57 (1926).—Co electrodes were placed in distd. H_2O p_H 6.4 and in a soln. of Co-protein also p_H 6.4 made by shaking albumin with powdered Co. The potential of Co^{++} with respect to H_2O was calcd. from the formula: $E = (0.0577/V_2) \log_{10} ([M_2^{(n)}]/L_{M_2})$ 3.108 derived from Smits' and Aten's work (*C. A.* 11, 904). The calcd. value was -0.708 v.; the found value at 18° was -0.705 . The potential of Co^{++} with respect to Co-protein was -0.648 v. Curves are given showing the variation of potential with time. The potential found with respect to H_2O agrees very well with the calcd. values; that with respect to Co-protein indicates the presence of Co^{++} ions in greater numbers than the limit of concn. at that p_H . The presence of free ions in that concn. leads the authors to conclude that Co-protein salts are present. II. G. B. BONINO AND A. GRANDI. *Ibid* 258-76.—Expts. were made to prove that the reaction between a metal and a protein (Co and gelatin) is governed by the amphoteric properties of the gelatin. The following assumptions were covered: (a) the metal reacts with the protein and lowers its H-ion concn.; (b) the elec. cond. and η of the gelatin in the zone $[H^+] > [H^+]_i$ (isoelec.) are diminished by the action of the metal on the protein; (c) the same properties are increased by the action of the metal on gelatin when $[H^+] < [H^+]_i$; (d) the total quantity of metal fixed depends on the initial H-ion concn.; (e) the curve expressing the total metal fixed by gelatin at various p_H shows a min. at the isoelec. point. The p_H of the protein solns. were detd. by the quinhydrone electrode modified according to Sørensen to eliminate salt errors. Cond. measurements were made by the Kohlrausch method; η measurements by the Ostwald viscometer. One-g. portions of isoelec. gelatin prepd. according to Loeb were placed in various beakers; 100 cc. HCl of different concns. was added to each beaker, allowed to stand 30 min. at 20° and then the whole poured over filter paper to drain the excess liquid and finally washed with 25 cc. distd. H_2O . The gelatin was melted at 30° and brought to 100 cc. with H_2O . A portion was removed for control tests, the remainder was shaken with powdered Co reduced at red heat by H_2 and incubated at 30° for 24 hrs. The controls were also incubated. On removal the p_H , elec. cond., and η were detd. The expl. data are reported in the form of tables showing the relation between p_H and elec. cond.; p_H and η . The results confirm the hypothesis, that the reaction between Co and gelatin is similar to that of a metal and an amphoteric electrolyte: (a) there was a decrease in H-ion concn.; (b) a diminution in cond. and η when $[H^+] > [H^+]_i$; (c) an increase of cond. and η when $[H^+] < [H^+]_i$; (d) the amt. of Co fixed depends on the initial p_H ; (e) the curve representing the Co fixed with respect to initial p_H shows a min. at the isoelec. point. III. The application of the theory of membrane equilibrium in the case of cobalt and gelatin. *Ibid* 277-88.—If a soln. of Co-protein at a given p_H is sepd. by a collodion membrane from a soln. of $CoCl_2$, certain fundamental relations may be deduced from Donnan's theory of membrane equil.: (a) The value for E in systems contg. solns. qual. equal and quant. similar should be about equal or const.; (b) by increasing the concn. of total Co the ratios H_1^+/H_2^+ and $E\sqrt{(Co_{tot})_1/(Co_{tot})_2}$ should diminish but be greater than unity; (c) the same diminution should be noted if a strong electrolyte which does not alter the p_H is added to the system; (d) when the p_H of the system is less than 4.7 the values of the above ratios should be less than unity and increase in the same proportion as the increase in concn. of the anion of the acid outside the membrane. (1) Flasks contg. 1% gelatin at different p_H were prepd. as previously described. They were incubated at 30° for 12 hrs. with Co powder. They were removed and the p_H of the gelatin in each flask was detd. The gelatin was placed in 7 collodion sacs closed at the top with a perforated stopper through which passed a thin glass tube 40-50 cm. long. Each sac was placed in a beaker contg. 0.002 N $CoCl_2$. After 5-6 days the p_H and total Co were detd. on each side of the membrane. (2) Five flasks of gelatin at different p_H were also placed in sacs except that the gelatin had not been in contact with Co. The sacs were placed in beakers contg. distd. H_2O at the bottom of which was a 0.5-mm. layer of activated Co powder. They were left standing for 4-5 days after which the p_H and total Co were detd. on each side of the membrane. (3) Another series of flasks was treated similar to (1) except the sacs were immersed in 0.002 N $CoCl_2$ and HCl of different concns. (4) In this series the sacs were immersed in beakers containing 0.002 N $CoCl_2$ and N KCl. The data reported in tabular form confirm all the deductions (a), (b), (c), (d) derived from Donnan's theory and show that powdered Co acting on gelatin at p_H 2 to 7 forms Co-protein salts. IV. The action of cobalt on gelatin at $p_H > 7$. *Ibid* 289-92.—If powdered Co is placed in contact with gelatin of $p_H > 7$, the Co fixed by the protein should be inversely proportional to the p_H . The ampholyte functions as a weak acid and thus the elec. cond. increases. The increase, however, is inversely proportional to the p_H

until it reaches zero as a limit, a point where the protein no longer fixes the metal in the ionic state. Five 1-g. samples of isoelec. gelatin were treated at 10° with NaOH solns. of varying concns. The gelatin was washed and melted as already described. They were brought to 100 cc at 30° with distd. H₂O. Part of the solns. were kept as controls, the remainder incubated at 30° with powdered Co. After 24 hrs. the p_H and elec. cond. were detd. on the control samples, and p_H , elec. cond. and total Co on the samples treated with the metallic powder. The p_H was detd. by means of the H electrode. The results are given in tabular form and confirm the theoretical deductions. However, in some cases at high p_H where the increase in elec. cond. was nil or even negative, the fixation of Co was about 34% of that fixed in the sample with the max. increase in cond. Co-gelatin solns. formed at $p_H < 7$ had a weak rose color; those at $p_H > 7$ had a yellowish color almost brownish. The color is intensified if the Co-gelatin solns. are agitated with a current of air or other oxidizing agent. This treatment increases the total Co fixed, but there is not an analogous increase in elec. cond. or variation in p_H . Besides the cobaltous ion corresponding to Co-gelatin salts, there must be present also trivalent Co in the form of cobaltamines. PETER MASUCCI

Quantitative variations in the glutathione of isolated organs. S. VISCO AND S. CASTAGNA. *Boll. soc. ital. biol. sper.* 3, 282-3 (1928).—In isolated beef liver kept at a temp. 10° ± 1° the reduced glutathione content remains const. for the first 2 hrs. and then begins to decrease gradually until it reaches a min. after 24-32 hrs. After this min. a rapid increase takes place and reaches values greater than the initial one. From 90 to 96 hrs. after extirpation there is a complete disappearance of reduced glutathione. Tunncliffe's method was used for the detns. PETER MASUCCI

The present knowledge of the chemical constitution of leucocyte granules. I. Introduction. II. Indirect methods for studying the nature of leucocyte granules. ALFRED NEUMANN. *Folia Haematol.* 36, 95-144 (1928). **III. Direct methods for studying the chemical nature of leucocytes granules.** *Ibid.* 248-88. This is a very complete crit. review, including the literature. JOHN T. MYERS

New ultra-penetrating rays and the living cell. ALBERT NOBON. *Rev. sci.* 65, 609-17 (1927); cf. *C. A.* 16, 2636; 18, 1305, 1838. —The equipment used and results obtained are given in more detail. On the whole, the radioactivity of living vegetable tissues is of the same order of magnitude as that of U, and is greater in the reproductive organs than in other parts of plants: it is greater in freshly cut than in partially faded plants, and is entirely absent in dried plants. It undergoes slight variations from day to day, as with Ra and U, which seems to depend on the degree of activity of ultra-radiations. It is reduced by interposing a thick Pb screen in the path of the sun's rays. In the absence of sunlight, it is practically the same inside and outside a closed chamber (ultra-penetrating rays of cosmic origin). Very appreciable differences are sometimes observed in the emission of + or - ions, in which case the plant has an excess + or - charge, showing that a vegetable cell can spontaneously have a + or - charge. Soil freshly taken from the fields has a radioactivity comparable to that of fresh plants, which decreases as the soil dries out and is nil with soil from a damp cellar. The radioactivity of insects is from 3 to 15 times as great as that of U, the radioactivity of sick insects is appreciably lower than that of healthy ones, being of the same order of magnitude as that of plants, dead insects are not radioactive. N. suggests a theory whereby the results obtained would be accounted for by the action of ultra-penetrating rays (ultra rays), which may reach as far as wave lengths of 10⁻¹¹ cm.; and he also puts forth the suggestion that the origin of biological energy and the whole problem of living matter are dependent on these rays and their intraelectronic effects. A. PAPINKAU-COUTURE

The lipid question. BRUNO REWALD. *Chem. Ztg.* 52, 477-8 (1928). —The term *lipoid* is the best for this class of substances, "lipin," "lipide," etc., should be discontinued. The concept should not include the sterols, which are a class to themselves. So long as the constitution of individual lipoids is unknown they should be called *liver lipoids*, *egg-yolk lipoids*, etc. The purest "lecithin" is still a mixt., and many of the formulas given are very doubtful. Recommendations are made for the *deln.* of lipoids. AUSTIN M. PATTERSON

Temperature and life. Complex nature of the effects of temperature on the rates of certain biological processes. MERKEL H. JACOBS. *Am. Nat.* 62, 289-97 (1928). —**Temperature as an ecological factor in animals.** ROYAL N. CHAPMAN. *Ibid.* 298-309. —**Relation of temperature to the development of disease in plants.** JAMES G. DICKINSON AND JAMES R. HOLBERT. *Ibid.* 311-22. —Wheat seedlings blight in a warm soil but not in a cold soil. Corn seedlings blight in a cold soil but not in a warm soil. The cortical invasion and rotting are due largely to an unbalanced metabolism within the seed-

ling during the early stages of germination which resulted in the cell walls of the protective tissues composed of intermediate pectin-like substances instead of cellulose reinforced with lignin. These walls were easily hydrolyzed which allowed a rapid invasion by the parasite. The unfavorable environment was used in selecting resistant strains. Selecting for resistance in segregating inbred lines of corn grown in cold soils infested with the parasite has resulted in resistant lines growing well at low temps. These lines, in contrast with susceptible lines, show that the "inheritable resistance" is similar in nature to the "induced resistance" brought about by high soil temps. Resistance appears to be due to an intensification and stabilization of factors controlling a balanced seedling metabolism. This results in cellulose walls well reinforced with suberin and a cell compn unsuitable for the nutrition of the parasite over a wide range of unfavorable environmental conditions. L. W. RIGGS

Mineralogical forms of limestone in living beings and the problem of their determination. MARCEL PRENANT. *Biol. Rev. Biol. Proc. Cambridge Phil. Soc.* 2, 365-93 (1927) (In French, cf Johnston, Merwin and Williamson, *C. A.* 10, 2183).—The topics considered are the mineralogical forms of limestone, their properties, their distribution in living organisms and the causes which det. the production of the different forms. The subject is illustrated by equil. diagrams involving the pressure of CO_2 , concn of CO_2 , p_{H} and the log of the concn of the metallic ions (Cf. *C. A.* 22, 640) L. W. R.

Some physical and chemical properties of serum proteins. MAURICE PIETTRE. *Compt. rend.* 186, 1657-9(1928) From the phys. point of view, proteins are hardly to be considered as buffers, this role being attributed to mineral or org. impurities which accompany proteins. The p_{H} values of biologic media follow the dispersing medium more than the substances dispersed. Chemically the peptide groups are in the anhydride form. The indifference of the 2 principal proteins to acids and alk. bases guarantee to the humoral equal a precise stability L. W. RIGGS

Photometric determination of the permeability of olive oil toward ultra-violet light. E. ROUSSEAU. *Compt. rend. soc. biol.* 96, 611-2(1927); cf. *C. A.* 21, 2612. L. W. R.

Variations of the index of refraction of serum and plasma treated with ultra-violet radiations. J. CLUZET AND T. KOFMANN. *Compt. rend. soc. biol.* 98, 978-9(1928).—Normal horse serum at 20° increased progressively its n from 1.3466 to 1.3531 during 30 min. of irradiation. Another horse serum increased n from 1.3470 to 1.3527. With antitetanic, antistreptococic and antidiphtheritic serums there was a similar increase of n upon irradiation. Beef plasma showed an increase of n from 1.3504 to 1.3535 after 30 min. of irradiation. The change in n is attributed to a change in the state of the proteins present in the serum or plasma L. W. RIGGS

Adsorption of glucose by albuminoid precipitates. J. H. CASCAO DE ANCIA'S AND CARLOS TRINCAO. *Compt. rend. soc. biol.* 98, 1003-5(1928).—The sums of the reducing powers of 4 pairs of solns. of glucose and albumin were 1.87, 2.27, 1.74 and 2.38. When these pairs of solns. were mixed the reducing powers of the mixts. were 1.52, 1.90, 1.36 and 2.09. The differences, 0.35, 0.37, 0.38 and 0.29 represent the adsorption of glucose by albumin L. W. RIGGS

Means of preventing the adsorption of glucose by albuminous precipitates. J. H. CASCAO DE ANCIA'S AND CARLOS TRINCAO. *Compt. rend. soc. biol.* 98, 1586-8(1928); cf. preceding abstract.—By dissolving the albumin in a 5% soln. of NaCl instead of water, the adsorption of glucose by the albumin was almost completely prevented. L. W. RIGGS

Motility of the digestive tube in a decalcified medium, under the influence of ultra-violet rays. T. VACEK. *Compt. rend. soc. biol.* 98, 1025-6(1928). **Influence of ultra-violet rays on the motility of the muscular coats of the digestive tube.** *Ibid* 1027-8. L. W. RIGGS

Biologic role of calcium salts. L. AMBARD AND F. SCHMID. *Compt. rend. soc. biol.* 98, 1220-2(1928).—The subject is discussed from the equil. point of view of solns. of CaCl_2 , NaCl , H_2CO_3 , NaHCO_3 , and albumin. L. W. RIGGS

Study of the gaseous products which arise by the action of oxygen on glucose in an alkaline medium. Apparatus and technic. MAURICE NICLOUX. *Compt. rend. soc. biol.* 98, 1225-8(1928).—By the method employed, 0.250 g. of glucose dissolved in 0.1 N KOH and acted on by 50 cc. of O yielded 1.6 to 1.7 cc. of CO at a temp. of 84° . With 1.5 g. of glucose in 0.2 N KOH and 80 to 90 cc. of O at 84° enough CO was obtained to be kindled with a match. L. W. RIGGS

Imbibition by the vagal liquid. A. LAMBRECHTS AND H. FREDERICQ. *Compt. rend. soc. biol.* 98, 1244-6(1928).—The beginning of hemolysis of normal human red corpuscles takes place in a stronger concn. of hypotonized vagal liquid than in the analogous liquid of repose. The excitation of the vagosympathetic of the frog liberates

substances capable of diminishing the resistance of the corpuscles by increasing their imbibition. These expts. confirm the results obtained by aid of the muscle stria, which have also shown that the vaginal liquid favors the imbibition of protoplasmic colloids. **Action of acetylcholine on the imbibition of muscle stria.** *Ibid* 1246-7.—Acetylcholine increases the imbibition of the muscle stria of the frog and shows a close parallelism to the action of the vaginal liquid. L. W. RIGGS

Carotinemia and plasmatic xanthochrome. N. FLEISSINGER, H. WALTER AND J. E. THIERRY. *Compt. rend. soc. biol.* 98, 1297-9(1928).—In the colorimetric detn. of the biliary index of the blood plasma the subject should avoid foods rich in carotinoid pigments, such as carrots, pumpkins, oranges, etc., during the 24 hrs. before the samples for index detn. are taken. **Physiologic variations of the plasmatic xanthochrome in man.** *Ibid* 1299-1301.—The variations of the biliary index of the plasma are reported for several patients. The colorimetric estn. of the bilirubin of the blood serum gives an easily obtained approx. value of the cholemia, provided those foods which color the serum are excluded from the diet. L. W. RIGGS

Properties of filaments of coagulated gelatin. R. COLLIN. *Compt. rend. soc. biol.* 98, 1353-5(1928).—The color reactions of the filaments of coagulated gelatins are the same as those of fibrils of collagen. The probable relations of collagen and gelatin are discussed. L. W. RIGGS

Action of heat on the protein materials of the blood serum. SERVER KIAMIL AND RASSIM AALI. *Compt. rend. soc. biol.* 98, 1419-20(1928).—The protein materials of guinea pig serum show the least variations in the contents of globulin and albumin. Serums of guinea pig, rabbit and sheep when heated to 56° have varying quantities of their serum albumin transformed into serum globulin. The quantity transformed varies with the time but not always directly. The complement is not at all subject to the content of serum albumin and serum globulin in the serum. L. W. RIGGS

Fermentative processes. Action of amylase. YVONNE SCHAEFFER. *Compt. rend. soc. biol.* 98, 1491-4(1928).—The substrate was prepd. from potato starch according to the method of Mme. Gruzewska and the enzyme from saliva according to the method of Cohnheim. The amylose substrate after autoclaving for 2 hrs. at 130° was dild. to 0.05 to 0.007%, its p_H was adjusted to 6.7 when it was distributed in 10-cc. portions in tubes. To these samples was added 1 cc. of the saliva prepn. of variable prepn and concn. and the mixt. was placed in a thermostat. At varying intervals of time tubes were removed and plunged into boiling water for 3 min. to arrest the action of the enzyme, after which the sugar in the tubes was detd. according to Bertrand. The results expressed in curves show the total quantity of sugar produced, also the quantity produced per unit of time. This velocity of reaction was greatest during the period 75 to 100 min. after the addn. of the enzyme, when about 10 times as much sugar was produced as during any other 25 min. L. W. RIGGS

Relations between the increase of permeability of the hemato-encephalic barrier and the alterations of its morphologic substratum. L. STERN AND J. L. RAPOPORT. *Compt. rend. soc. biol.* 98, 1515-7(1928), cf. C. A. 21, 3973.—Exchanges between the cerebrospinal fluid and the cerebrospinal nerve elements. *Ibid* 1518-9. L. W. R.

Coagulation of egg white by biologic agents. E. LAGRANGE. *Compt. rend. soc. biol.* 98, 1527-9(1928).—Many tests are described and the possible relations of micro-organisms to the results are discussed. L. W. RIGGS

Absorption of ethylene by the blood, serum and water. Determination of the coefficient of solubility. MAURICE NICLOUX AND SCOTTI-FOGLIENI. *Compt. rend. soc. biol.* 98, 1544 7(1928); cf. C. A. 22, 1608.—Pure C_2H_4 , 85% or 36% C_2H_4 with air is absorbed by water, serum or blood in amts. proportional to the partial pressures of C_2H_4 , and according to Henry's law. The coeff. of soly. of C_2H_4 in water, serum or blood decreases regularly as the temp. rises and between 20° and 40° falls from 0.11 to 0.07. The coeff. is higher for blood than for its serum, for swine than for beef blood and has practically the same figure for water, swine or beef serum. Previous studies have shown that the coeffs. of soly. for vapors of $CHCl_3$ and C_2H_5Cl were higher for swine blood than for beef blood. L. W. RIGGS

Production of carbon monoxide by the action of oxygen or air on glucose in alkaline solution. Influence of temperature and alkalinity. MAURICE NICLOUX. *Compt. rend. soc. biol.* 98, 1548-51(1928); cf. C. A. 22, 2742.—A 0.5% soln. of glucose, a temp. of 84° to 85° and an alk. of 0.1 N are the most favorable conditions for the production of CO by the action of O or air on glucose solns. L. W. RIGGS

Modifications of glucemia in normal subjects by irradiation of the pancreas. FERNANDO FONSECA AND CARLOS TRINCAO. *Compt. rend. soc. biol.* 98, 1591-2(1928).—Irradiation of the pancreas by x-rays, $1/2$ of an erythematous dose being used, causes

a lowering of the glucemia in the fasting subject and modifications of the glucemia curve which are attributable to a hyperinsulinemia. Effect of irradiation of the pancreas on the glucemia and glucosuria of diabetes. *Ibid* 1593-4.—X-rays have an excitant action on the endocrine function of the pancreas. It is argued that x-ray treatment may supplement or replace in part insulin treatment of diabetes. L. W. R.

Reticuline-M, a product of the internal secretion of the reticulo-endothelial system. I. MOLDOVAN. *Compt. rend. soc. biol.* 98, 1617-9(1928).—The blockage of the reticulo-endothelial system by the intravenous injection of India ink is followed by the appearance in the blood of a substance which dialyzes readily through thick collodion membrane, is sol. in alc. and appears to resemble the amines. This product of the internal secretion of the reticulo-endothelial system is considered a hormone and is named reticuline-M in memory of Metchnikoff. L. W. RIGGS

Swelling as a function of the pH of organized membranes. M. CHANOT AND R. NOEL. *Compt. rend. soc. biol.* 99, 67-9(1928).—Fragments of the stomach of a calf recently killed showed a min. of swelling at the isoelec. point. The swelling increased as the medium was made more alk. with NaOH or more acid with citric acid. L. W. RIGGS

Spontaneous modification of the viscosity of fresh blood serum. LÉCOMTE DU NOUV. *Science* 67, 563-4(1928); cf. *C. A.* 21, 2499.—Horse serum centrifuged immediately after sepn. from the clot and placed in the viscometer behaved in the following way: At first its viscosity, which is rather high, increases for about 10 min., then decreases rapidly almost proportionally to the time, and finally reaches a stable value lower than the original one. Toward the end the curve is logarithmic. The total phenomenon requires from 1 to 2 hrs., the time depending apparently on the amt. of handling to which the serum has been submitted. An hypothesis is offered to account for this action. L. W. RIGGS

Enzymic mutation and enzymic formation of lactic acid from glycogen. HANS V. EULER AND EDVARD BRUNIUS. *Svensk Kem. Tids.* 39, 287-95(1927); cf. *C. A.* 22, 2384.—Experiments with two dried muscle preparations. HANS V. EULER AND STIG PROFFE. *Ibid* 295-7. (In German).—Mutase is identical with carbohydrate-dehydrogenase (Thunberg), perhydridase (Bach) and Schardinger-enzyme. Mutase activity was noted in press juice from liver and muscle, more active in the former than in the latter. Activity is not diminished by AcOH deproteinization but is diminished by dialysis and by colloidal Fe pptn. Mutase and cozymase are both present in dried muscle from ox and rabbit. Enzymes causing mutation and lactic acid formation do not show parallel activity factors in extracts from liver and muscle. Mutase activity was tested by destruction of AcH (Cannizzaro reaction) (*C. A.* 21, 3065). A. R. R.

The plasma membrane of ox erythrocytes as studied by Wheatstone bridge measurements. J. F. McCLENDON. Univ. of Minn. *Protoplasma* 3, 7-10(1927).—The measurements of elec. impedance of blood (Z_0) at $f = 0$ (direct current) were made with a Christiansen ionometer, those at $f = 1000$ with a Vreeland oscillator, Wheatstone bridge and 2-stage amplifier and those at $f = 1,500,000$ with an electron tube oscillator and Wheatstone bridge, with heterodyne detection and 2-stage amplification of the beat-note of 1000 cycles per sec. The oscillator, Wheatstone bridge, amplifier, heterodyne and all connections, transformers, and A and B batteries were enclosed in grounded Cu shields. The impedance of corpuscles (100% cell vol.) at 1000 cycles is from 4.705 to 7.06 times as great as at 1,500,000 cycles. This is not due to variations at 1,500,000 for they are only from 335.3 to 442.9 but to variations at 1000 cycles which are from 1747 to 2590. The specific impedance (resistance) of the corpuscle interior is probably very close to 335.3 to 442.9 or roughly about 400 ohms. The greater specific impedance of the corpuscle at 1000 cycles are due to the impedance (reactance) of the plasma membrane, and if 400 ohms are subtracted from this impedance, the impedance of the plasma membrane is calcd. to be 1747-400 to 2590-400 or 1347 to 2190 ohms. This great variation of the impedance of the plasma membrane is probably due to injury caused by handling, as it is observed that handling (centrifuging, defibrinating, storing) the blood always decreases the impedance. The impedance of the uninjured plasma membranes in 1 cm. of blood is probably 2190 ohms or higher. On laking the corpuscles the impedance at 1000 and 1,500,000 cycles is the same. M. H. SOULE

A general reaction of amino acids (DAKIN, WEST) 10.

B—METHODS AND APPARATUS

STANLEY R. BENEDICT

Composition of the blood of children. G. DE TONI. *Clin. pediatr.* **8**, 449-93 (1926).—A system of analytical methods is described. B. C. A.

Clinical methods for the determination of hemoglobin. E. M. F. ITHURRAT and V. MORERA. *Rev. asoc. med. Argentina* **39**, 401-26 (1926). Newcomer's method is recommended although Birker's method is more accurate. B. C. A.

Method for the determination of the weight of particles, based upon the phenomenon of isothermal distillation, and its application to the measurement of particle concentration in blood serum and of physiological solutions. AURELIA RYCHTEROWNA. *Arb. Kommission Math. Naturwiss. Posen*, Series A **2**, 29-71 (1925). *Chem. Zentr.* **1927**, I, 2582.—The expts. had as their object the detn. as precisely as possible of the compn. and properties (osmotic pressure, sp. cond., p_H value, etc.) of human blood serum, in order to utilize the results in the prepn. of a physiol. soln. as nearly identical as possible with blood serum. The most suitable method for detg. particle concn. appeared to be that of Barger (*Ber.* **37**, 1754 (1904)) improved by Rast (*C. A.* **16**, 519), since this had the advantage over the ordinarily used cryoscopic methods that all measurements could be made at the temp. of blood. Measurements with a cathetometer showed that the reason for the transfer of a solvent from a weaker soln. to a more concd. soln., which are sepd. by an air bubble in a narrow sealed tube, is not as maintained by Yamakami (*C. A.* **14**, 1913) solely an osmotic phenomenon, but results from isothermal distn. of the solvent. With the method of Rast it was proved that the error of 0.01 g.-mol. with nonelectrolytes is never exceeded. The times for equil. to be established at 36.5° in glass tubes with aq. solns. and with blood serum were detd. By modifying the method of Rast, including the use of a const. temp., the precision was increased to 0.005 g.-mols. even in measuring the particle concn. of electrolytes. By applying this micro-method to the detn. of particle concn. in serum, it was found that this was 0.200-0.302 g.-mols. per l. With the aid of this method and cond. detns., certain physiol. solns. used in medicine were compared, and the compn. of one physiol. soln. was derived.

C. C. DAVIS

Microchemistry and microphysics in the service of tissue hygiene. New methods for the diagnosis of lead poisoning. P. SCHMITT. *Mikrochemie* **5**, 8-11; *Chem. Zentr.* **1927**, I, 2122. The order of magnitude of the quantities of Pb in the blood, cerebrospinal fluid and urine is such that only a colorimetric method is suitable for its detn. The use of Arnold-Mentzel reagent on superoxide (tetramethyldiaminodiphenylmethane) (cf. *Ber.* **35**, 2902) gives satisfactory results if the microanalysis is improved in the following way. After destruction of org. substances ($\text{HNO}_3 + \text{H}_2\text{SO}_4$) ppt. the heavy metals by H_2S under pressure in ammoniacal soln., sep. on the asbestos filter Fe and Mn by means of $\text{EtOH} + \text{H}_2\text{SO}_4$ and Cu by KCN, dissolve the PbS in HNO_3 , oxidize with NaClO on the boiling water bath, filter off the PbO_2 on a Schott asbestos glass filter, after addn. of Arnold-Mentzel reagent dissolve in AcOH . A blue color indicates Pb. The optimum time of pptn. is 24-36 hrs., for too long a passage of H_2S increases the dispersion of PbS so that it passes through the filter. After soln. of the PbS in HNO_3 , it must be washed to recover any PbSO_4 formed. Before the oxidation it is essential to neutralize and oxidation should be effected with excess NaClO . Every trace of NaClO should be removed by washing with cold water. Microanalysis gives only approx. results and requires supplementary examn. by spectral analysis. By the use of C electrodes and an asbestos filter in the spark gap, the PbO_2 can be infiltrated on the smallest surface, so that the greatest possible concn. of Pb vapor in the elec. spark is obtained. Quantities of Pb under 0.005 mg. can thus be caught. Besides being useful in practical diagnosis, the new method also gives a clue to the character of Pb poisoning and the distribution of Pb in the organs and cells. Pb appears even in traces to act primarily as a poison to the cell nuclei.

C. C. DAVIS

The preparation of the unaltered modification of hydroxyhemin and chlorohemin. A. HAMSIK. *Z. physiol. Chem.* **176**, 173-86(1928).—In order to prep. the unaltered or α -modification of hydroxyhemin and chlorohemin from defibrinated blood it is necessary to avoid so far as possible the presence of free mineral acid in the pigment solns. The following procedure is the least likely to cause such alteration. Defibrinated blood is coagulated with MeAc, the coagulum freed from chlorides and extd. with a mixt. of MeAc and $(\text{COOH})_2$. For the prepn. of hydroxyhemin the ext. is treated with NaOAc; for the prepn. of chlorohemin it is treated with dil. HCl, until the pigment rapidly ppts. out. The ppt. is sepd. as soon as possible from the mother liquor and washed. Other prepn. in which EtOH was used in place of MeAc, or H_2SO_4 in place of $(\text{COOH})_2$, contained varying amts. of the altered or β -modification of the pigment. A. W. D.

Studies on the Folin method of analysis for glucose in normal urine. R. H. HAMILTON, JR. Univ. of Minnesota. *J. Biol. Chem.* **78**, 63-5(1928).—By using acid-treated Lloyd's reagent one can dispense with the use of permute in Folin's method for detg. glucose in urine. The reagent is acid-treated by extg. for 24 hrs. with concd. HCl, washing and drying and repeating the procedure with concd. HNO_3 . A. G.

Determination of total chlorine and weakly combined chlorine in the gastric juice. D. RAGUET AND PAGET. *Ann. chim. anal. chim. appl.* **10**, 161-2(1928).—It is sometimes desired to know not only the amt. of free HCl but also the Cl combined with org. material and that present as salt of a mineral base. Details are given for carrying out an argentometric detn. of these 3 kinds of Cl. By evapg. to dryness and calcining the residue, the Cl present as metallic chloride is obtained. By evapg. of the water bath, the free HCl is removed, and then by calcining with soda and niter, the Cl present as org. Cl compd. is obtained together with that of the inorg. salt. Finally the total Cl can be obtained by adding alkali at the start and then evapg., and calcining.

W. T. H.

Determination of traces of mercury. III. Determination of mercury in urine and feces and the influence of medication. N. E. SCHREIBER, TORALD SOLLMANN AND HAROLD SIMMONS BOOTH. Western Reserve Univ. *J. Am. Chem. Soc.* **50**, 1620-5(1928).—With normal urine, the method of Booth, Schreiber and Zwick gives Hg results within 0.01 and 0.02 mg. Long standing without freezing does not alter the Hg content of urine. Dosage of arsenophenamine, Bi subnitrate, chloral hydrate, barbital and small amts. of urotropine bromide do not interfere with the standard procedure. On the other hand, aromatic compds. such as Na salicylate, cinchophen and large quantities of urotropine complicate the oxidation so much that it is inadvisable to administer these drugs during a study of mercurial medication. Iodides and considerable bromide interfere seriously but such interference can be easily taken care of by a modified procedure which is described. In the analysis of feces decompn. with KMnO_4 and concd. HNO_3 proved satisfactory and 2-3 mg. in the daily stool can be detd. with a loss of 0.01-0.04 mg.

W. T. H.

Myothermic apparatus. A. V. HILL. Univ. of London. *Proc. Roy. Soc. (London)* **B103**, 117-37(1928).—The app. includes a moving-coil galvanometer of high sensitivity and short period, a thermostat in which the temp. is maintained const. within 0.001° for long periods, and an all-metal thermopile which responds quickly, settles down rapidly and is very completely insulated. Total heat is measured from the area of the deflection time curve. The gases employed (N_2 , O_2 and CO_2) are especially purified. A Ringer soln., contg. 7 to 10 mg. P as Na phosphate per 100 cc. and with a p_{H} of approx. 7.2, is the most suitable medium.

JOSEPH S. HEPBURN

Glyoxals. NORIYU ARIYAMA. Wash. Univ. Med. School. *J. Biol. Chem.* **77**, 359-94(1928); cf. C. A. **22**, 1784.—A new colorimetric method for the detn. of glyoxals is described based on their marked reducing action in alk. soln. in the presence of cyanide. The color is developed by using Benedict's arsenophosphotungstic acid reagent followed by NaCN and Na_2CO_3 . $\text{CCl}_3\text{CO}_2\text{H}$ is used to ppt. protein from the solns. to be analyzed. The glyoxals are quite stable up to a p_{H} of 8.0. At higher p_{H} values the transformation of glyoxal proceeds at the rate of a monomol. reaction, the rate increasing a trifle more slowly than the OH-ion concn. of the soln. The quant. formation of the corresponding hydroxy acid does not occur below p_{H} 12. The glyoxalase of tissue exts. is most active at p_{H} 7.0 and converts Me glyoxal quant. to lactic acid. It is most abundant in the liver. The "antiglyoxalase" of the pancreas inhibits the action of glyoxalase only when it has been kept in contact with it for some time before the addn. of the glyoxal. There is considerable doubt as to the enzymic nature of this substance. Insulin has no effect. Glyoxals are strongly decompd. catalytically by alk. KCN soln. but lactic acid is not produced and it has not been possible to identify the substance formed.

A high reduction intensity develops when glyoxals are destroyed by KCN; this has not been observed when the decompn. is effected by glyoxalase or alkali. A. P. L.

The validity of the ethyl iodide method for measuring the circulation. YANDELL HENDERSON AND HOWARD W. HAGGARD. Yale Univ. *Am. J. Physiol.* **82**, 497-503 (1927); cf. C. A. **21**, 431.—A defense of the author's method for the detn. of circulation in man. J. F. LYMAN

Comparative measurements of the circulation in man with carbon dioxide and ethyl iodide. R. J. BROCKLEHURST, H. W. HAGGARD AND YANDELL HENDERSON. Yale. *Am. J. Physiol.* **82**, 504-11(1927).—The arterio-venous CO₂ difference in a healthy man at rest is probably about 3.5 vols. % and his circulation, on the assumption of 234 cc. per min. CO₂ production, is, therefore, 6000 cc. This value agrees closely with that found by the EtI method. The procedure for detg. the circulation rate by means of CO₂ is described and consists essentially in finding the difference between samples of arterial alveolar air and venous alveolar air (the latter obtained from a rubber bag contg. O₂ and CO₂ and whose contents were rebreathed in such a way as to give CO₂ equil. with the venous blood coming to the lungs). J. F. LYMAN

Photographic methods of estimating the percentage saturation of hemoglobin with various gases. I. The ratio of oxyhemoglobin to carboxyhemoglobin. H. HARTRIDGE AND F. J. W. ROUGHTON. Cambridge. *J. Physiol.* **64**, 405-14(1928).—Photographs of the α -band of the absorption spectra of the unknown blood solns. were compared with spectra of solns. of known compn. By the use of a selenium densitometer the mid point of the α -band was detd. The difference between the mid points of the band in 100% oxyhemoglobin and 100% CO hemoglobin amounts to about 3.5 m μ ; the accuracy of the method is higher than that given by the revision spectroscope and has the added advantage of giving a permanent record free from subjective errors. J. F. LYMAN

A new method for staining reticular tissue. I. G. RASTELLI AND P. MASCHERPA. *Boll. soc. ital. biol. sper.* **3**, 188-91(1928).—A technic for staining reticular tissue is described. Histological sections are passed through an aq.-alc. soln. of pyrrrole, washed, and placed in a 0.1% sol. AuCl₃. The sections are washed again, passed through alc., xylene, and Canada balsam. A brown-violet to a black color appears in 3-6 hrs. The mechanism of staining is explained. Pyrrrole has a special affinity for the proteins of the reticular tissue, and this affinity is due to the mobile H. It is fixed by the proteins through the NH group. The AuCl₃ reacts with the carbon atoms of the pyrrrole and forms colored compds. PETER MASUCCI

Glassmann's method for the determination of sugar. G. B. TAFURI. *Boll. soc. ital. biol. sper.* **3**, 203-4(1928).—The assumption that alc. exts. sugar only from the blood and urine is not correct. Other substances are extd. capable of giving condensation products with resorcinol. The method is, therefore, not reliable for the detn. of sugar in biol. fluids. PETER MASUCCI

A buret for the pharmacological study of very unstable colloids. L. SABBATANI. *Boll. soc. ital. biol. sper.* **3**, 205(1928).—Certain inorg. colloids cannot be stabilized by means of protective agents and flocculate quickly. To study the pharmacol. action of these S. has devised a double buret in which the two reacting solns. meet in a small mixing chamber close to the injecting cannula. Agitation is facilitated by means of an automatic mech. agitator while the solns. flow towards the vein of the animal. By lengthening the distance between the mixing chamber and injecting cannula the time between the prepn. of the colloid and its injection may be varied at will. P. M.

New method for the extraction of liquids. E. P. WIDMARK. *Bull. soc. chim. biol.* **10**, 669-74(1928).—In the app. the solvent liquid is made to run from the compartment contg. the liquid to be extd. into a compartment contg. an absorbing liquid which changes the compn. of the substance extd. so that it is no longer sol. in the solvent liquid. The solvent liquid then runs back to make a further extn. The movements of the solvent liquid are made by placing the extn. app. on a rocker driven by a motor. The process is accordingly named "extraction en berceau." I. W. RIGGS

Preparation of absorbent papers used in the micro-analysis of Bang. F. NERVENUX AND A. THÉPÉNIER. *Bull. soc. chim. biol.* **10**, 699-701(1928).—The paper should be of pure rag stock, white, smooth and rather thin. It should be cut in rectangles 25 × 10 mm., the pieces to weigh 75 to 80 mg. The papers are boiled 1 hr. in 10% AcOH then are drained and rinsed in boiling water on a Buchner funnel until the p_H is between 6.4 and 7.0, when the papers are dried at 37° and are preserved in a stoppered flask. I. W. RIGGS

Application of the micro-carbon method of Nicloux to the determination of urea by the intermediary of dixanthylurea. ANDRÉ BOIVIN. *Bull. soc. chim. biol.* **10**,

684-97(1928); cf. C. A. 21, 929.—The technic is based on the detn. of C in dixanthylurea by the sulfochromic method of Nicloux, except that Ag_2CrO_4 is not used as it leads to the formation of important quantities of CO. The method is sensitive to 1 to 0.1 mg.

L. W. RIGGS

Quantity of the residue of fermentation. Test of the value of a method for estimating blood sugars. G. FONTES AND L. THIVOLLE. *Compt. rend. soc. biol.* 98, 1218-20 (1928).—Since the blood contains reducing substances which are not sugars, those methods of estg. blood sugar which depend on reduction are faulty. It is proposed to deprive the blood of all sugars, without modifying the nature or quantity of the other constituents, then add a known quantity of glucose and redet. the added sugar quantitatively. In carrying out this proposition the sugars were removed by fermentation with *Fala* or *Royale* yeast. The residue (*reste*) of fermentation in 17 expts. averaged 0.0074 g. per l. and in 8 of the 17 tests there was no residue. Apparently the difference between the sugar recovered and that added represents the reducing substances not sugar. This gives a factor for correcting the results of the usual blood sugar detn.

L. W. RIGGS

Improvement of the Nicloux apparatus for the micro-determination of carbon. MAURICE NICLOUX. *Compt. rend. soc. biol.* 98, 1222-5(1928); cf. C. A. 21, 1945, 3642, 3857.—The changes from the previous forms of app. are illustrated and described.

L. W. RIGGS

Colorimetric estimation in monochromatic light of cholesterol, glucose, uric acid and hemoglobin. P. LAURENT-GÉRARD. *Compt. rend. soc. biol.* 98, 1325-9(1928).—The utilization of the Vernes, Bricq and Yvon colorimeter with monochromatic screens specially selected for each color permits a more accurate estn. of the substances above named than by polychromatic light.

L. W. RIGGS

Method of estimating the oxidases in the tissues. J. LASKOWSKI. *Compt. rend. soc. biol.* 98, 1369-71(1928).—The method consists in the formation of iodophenyl blue under detd. conditions and its comparison with a colorimetric standard. L. W. R.

A note on the Koch and McMeekin method for the determination of nitrogen; with special reference to the non-protein nitrogen of blood and urine. H. A. DAVENPORT. *J. Lab. Clin. Med.* 12, 286-7(1926).—Ordinary 3% H_2O_2 (U. S. P.) instead of the 30% soln. may be used to clear the H_2SO_4 digests of blood and urine in microdetn. of non-protein N by the Koch-McMeekin procedure, provided a correction of 0.002 mg. N per drop (20 to 25 drops to the cc.) be made for N derived from the acetanilide.

ETHEL W. WICKWIRE

The estimation of plasma chlorides. ARNOLD E. OSTERBERG AND EDNA V. SCHMIDT. *J. Lab. Clin. Med.* 13, 172-5(1927).—Blood plasma chlorides checked in duplicate by the method of Whitehorn can be detd. in the presence of a protein ppt., AgCl and the yellow of FeC_2O_4 . Pipet 1 cc. of plasma into a 125-cc. Erlenmeyer flask; add 10 cc. of 1:3 HNO_3 from a buret slowly and with agitation of the blood plasma so that a white, flocculent ppt. of the plasma proteins is obtained. To this suspension add 5 cc. of N/35.46 AgNO_3 soln., then 1 cc. of 20% ferric ammonium sulfate soln. Titrate the excess Ag with N/35.46 NH_4CNS or KCNS . Since these solns. are of the same normality as that used in the Whitehorn method, calcs. are the same. One cc. of Ag soln. is equiv. to 1 mg. of Cl or 1.65 mg. of NaCl. The end point is the first trace of color which spreads throughout the whole soln. from the point at which the drop strikes while the flask is gently rotated.

E. W. WICKWIRE

Some useful modifications of the Haldane gas-analysis apparatus. VINCENT DU VIGNEAUD. *J. Lab. Clin. Med.* 13, 175-80(1927).

E. W. WICKWIRE

A modification of the McLean-Van Slyke method for the estimation of chlorides in blood. M. I. HANNA. *J. Lab. Clin. Med.* 13, 651-3(1928).—Dil. 1 part oxalated blood or plasma with 7 parts H_2O , wash the pipet with dil. blood, and drain twice. Add, as in the Folin-Wu method, 1 part 10% Na tungstate and 1 part $\frac{1}{2}$ N H_2SO_4 . Shake vigorously a few min., filter through a No. 40 Whatman filter paper into a dry flask. To 10 cc. of filtrate add 10 cc. of distd. H_2O and 5 cc. of M/29.25 AgNO_3 soln. Let stand 5 min., filter through 2 small No. 40 Whatman filter papers folded together. Pour a few drops down the sextupled side of the filter and allow to soak into the paper, then pour the remainder into the filter. To 10 cc. of filtrate, add 2 cc. of starch citrate nitrite soln. Titrate to the first permanent blue tint with M/73.1 KI soln., using a 5-cc. standardized buret with a capillary tip dropping from 50 to 60 drops per cc. 10.15—double the titration value = mg. NaCl per cc. of original blood. This method is shown to be accurate within 1% and requires a smaller amt. of time, work and blood filtrate for detn.

E. W. WICKWIRE

A simplified technic for studying the secretion of lymph. LESTER R. DRACUT

AND CARL A. DRAGSTEDT. *J. Lab. Clin. Med.* 13, 654(1928).—The thoracic duct can be made to stand out conspicuously if to the meal of fat previously given is added a small amt. of fat (butter) satd. with Sudan III. The intestinal lymphatics also stand out in marked contrast to the strands of fat in the mesentery and along the blood vessels.

E. W. WICKWIRE

The Bunsen valve in blood-urea determination. F. P. BROOKS. *J. Lab. Clin. Med.* 13, 668-70(1928).—The use of the simple Bunsen valve, which is described, is suggested as a substitute for the flutter valve devised by Johnson in blood-urea distn. by the Folin-Wu method. The use of fixing paraffin to prevent foaming is found to be satisfactory.

E. W. WICKWIRE

An aid in the estimation of blood calcium. E. M. WATSON. *J. Lab. Clin. Med.* 13, 670-1(1928).—An app. for titration of the pptd. CaC_2O_4 consists of a microburet contg. KMnO_4 , a centrifuge tube contg. the CaC_2O_4 dissolved in H_2SO_4 and immersed in a beaker of water heated to 75° , a thermometer and a piece of flask opal glass illuminated by an elec. bulb to serve as a background for detg. the end point.

E. W. W.

Note on the Volhard-Harvey method for the estimation of chlorides in urine. WILLIS H. JEFFERY. *J. Lab. Clin. Med.* 13, 687(1928).—Trials on different subjects showed that the ingestion of 1 aspirin tablet was sufficient to give a brownish violet color characteristic of the reagents employed in this method. In order to insure the observation of a sharp end point, the employment of an extra dish contg. an untitrated mixt. to serve as control, together with the first rough titration, was found indispensable.

Colorimetric comparison tests of blood. O. AMME. *Brit.* 280,551, Nov. 13, 1926. Strips of absorbent material may be dyed in different colors such as pompeian red, puré blue and blue with a slight greenish tinge; suspected diseased blood is placed on strips of the material, allowed to dry and the specimens are examd. by transmitted light and compared with healthy blood.

C - BACTERIOLOGY

A. K. BALLS

Some chemical changes accompanying the growth of tubercle bacilli on Long's synthetic medium. A preliminary study. TREAT B. JOHNSON AND ALICE G. RENFREW. *Am. Rev. Tuberculosis* 17, 508-19(1928).—The period of increasing growth of human tubercle bacilli (H37) on synthetic medium is characterized by continued changes in inorg. NH_3 content and in the p_{H} of the medium. When growth of the bacteria ceases, or the rate of growth is apparently balanced by the rate of cell autolysis, the p_{H} and NH_3 values become comparatively const. The use of protein free synthetic medium of known compn. for bacterial growth has made it possible to eliminate the ordinary complications arising from NH_3 and amines formed as a result of enzymic digestion of proteins. Exptl. data indicate that there is a correlation between the reaction changes and growth of bacilli, and the p_{H} curves obtained by Frothingham, Weinziel and Knapton, and by the authors are in close agreement. The sudden change in p_{H} at the end of 4 weeks' growth is concomitant with the appearance of reducing substances (sugars?) and coagulable protein in the medium. The growth of tubercle bacilli on Long's medium reached the max. during the sixth week of incubation. It remains to be detd. whether the intensity of color formation with Folin's uric acid reagent actually characterized the growth of other bacterial organisms as has been observed with tubercle bacillus used in this study.

H. J. CORPER

Biacetyl a metabolic product? HANS SCHMALFUSS AND HELENN BARTHEMEYER. *Z. physiol. Chem.* 176, 282-6(1928).—In cultures of lactic acid bacteria on sterilized milk Ac_2 was recognized by its odor and isolated and identified as the dioxime. From 5 l. of culture the yield was 1.7 mg. dioxime, m. 235° . It is possible that the Ac_2 is formed by oxidation of the known bacterial product AcMcCHOH .

A. W. D.

Alcohol fermentation. XVII. Pyruvic acid as an intermediary product of alcoholic yeast fermentation. S. KOSTYCHEV AND S. SOLDATENKOV. *Z. physiol. Chem.*

176, 287-91(1928).—Not only in lactic acid fermentation (*C. A.* 21, 3921) but also in alc. fermentation by yeast the formation of AcCO_2H can readily be demonstrated. If the fermentation is performed in the presence of $\text{NH}_2\text{CONHNH}_2$, NaOAc and CaCO_3 , the AcCO_2H is recovered as the Ca salt of its semicarbazone. No evidence was obtained of the presence of $(\text{NHCONH}_2)_2$ or of the disemicarbazone of AcCHO . The formation of AcCO_2H occurs, however, only when sugar is added to the fermentation mixt. Variations in temp. and reaction of the medium are of little influence. A. W. DOX

The porphyrin and blood pigment metabolism of the yeast cell. R. M. MAYER. *Z. physiol. Chem.* 177, 47-67(1928).—By means of the Konigsdorffler microspectroscope, with which the emission spectra of fluorescent solns. can be measured, the development of coproporphyrin in yeast grown on synthetic culture media was studied. The porphyrin is actually synthesized by the organism and not supplied by the culture medium. During successive cultures on a synthetic medium the yeast undergoes mutation to a degenerate form with greatly increased power of synthesizing coproporphyrin. Although there is no direct evidence that normal yeast is able to synthesize the porphyrin it is reasonably certain that such ability exists. So far as is known, pathologically degenerate cells in general do not acquire entirely new capacities, the pathological behavior being characterized merely by a decrease or an increase in the normal physiol. functions. Coproporphyrin has been found thus far only in dead yeast cells, and "coproyeast" would therefore represent a mixt. of such cells with living cells still capable of fermentation and proliferation. The synthesis of coproporphyrin may to a certain extent be regarded as the final effort of the coproyeast cell. Possibly the death of the cell is not a direct toxic effect of the high porphyrin content but occurs only through the influence of light. With light completely excluded living copro cells have been found in cultures 9 months old. A. W. DOX

The enzyme chemistry of acid formation by *Aspergillus niger*. K. BERNHAUER. *Z. physiol. Chem.* 177, 86-106(1928); cf. *C. A.* 21, 435.—In studying acid formation by *A. niger* a basal culture medium contg. KH_2PO_4 and MgSO_4 was used, and various substances were added as sources of C and N. After 4 days' growth on such medium at 35° , the soln. was replaced by a 2nd medium, usually a 10% glucose soln. to which CaCO_3 had been added, without disturbing the mycelium, and after another 4-day interval detns. were made of the gluconic acid formed. The conversion of glucose into gluconic acid is attributed to an enzyme "glucosidase," the term being understood to include any coenzyme complex involved in the reaction. Practically all substances capable of supplying C for development of the mycelium in the 1st medium appear to favor formation of glucosidase. The results were most uniform with sucrose, while with glucose, fructose, mannose, arabinose, glycerol and mannitol the acid production was variable and occasionally negative. Variations were also observed in the effect of different sources of N in the culture medium, the highest yield of gluconic acid being obtained with a mycelium grown on $(\text{NH}_4)_2\text{SO}_4$. Toxic substances in concns. sufficient to inhibit fungus growth do not interfere with gluconic acid formation by a fungus mat already formed. Addn. of such substances to the 2nd medium may even be advantageous in preventing contamination of the culture. On the other hand, these antiseptics completely suppress the formation of citric acid. It is, however, not definitely known that citric acid formation by molds is actually an enzymic process. Under certain conditions where the ability to form gluconic acid is lacking, the addn. of MnSO_4 to the 2nd medium promotes the reaction. For developing mycelia with the power to produce citric acid sucrose is a better nutrient than other carbon compds. When grown on glucose the fungus acquires this power only with nitrates as the source of N, and not with NH_4 salts, urea, asparagine, glycine or peptone. A. W. DOX

Cultural separation of bacteria on the basis of triphenylmethane coefficients. JOHN W. CHURCHMAN AND LOUIS SEGEL. *Stain Tech.* 3, 73-80(1928).—The general parallelism between the Gram reaction and normal selective bacteriostasis by the triphenylmethane dyes is well established, as is also the existence of a small number of organisms in each group which do not follow the rule. Reverse extrinsic bacteriostasis has been demonstrated, but only within a very limited field. The discovery of substances possessing reverse selective power, comparable in extent to normal selective power, would be of value. In the absence of such substances, the slight quant. differences in the behavior toward dyes, of organisms belonging to the same Gram group, may be turned to account. The authors detd. with great accuracy the crystal violet coeffs. of 5 Gram-positive and 5 Gram-negative organisms. These observations show that all known aerobic organisms could probably, on the basis of their triphenylmethane coeffs., be placed on a curve which would, on the whole, parallel the Gram reaction. The possibilities of sepg. Gram-negative organisms from Gram-positives by means of the

dyes are well understood. Similar sepns. can be within the Gram groups by making use of the quant. differences in triphenylmethane coeffs. C. R. FELLERS

The effect of the chemical nature of a decolorizer on its functioning. I. The Gram classification. ALLEN E. STEARN AND ESTHER W. STEARN. *Stain Tech.* 3, 81-6(1928).—Decolorizers which are distinctly acidic or basic in their chem. nature give abnormally high decolorization in the Gram stain for bacteria. Acidic substances yield more regular results. Ideally an "inert" decolorizer should be used, but ordinarily such substances will not dissolve the dye or dye-mordant ppt. from the smear. The most practical substances seem to be those so very slightly acidic in character as to be practically inert, such as acetone or EtOH or a mixt. of such substances. **II. The apparent isoelectric point.** *Ibid* 87-93.—The isoelec. point of a bacterial system is the H-ion concn. at which there is equal retention of anion and cation. By defining this point as that at which there is equal retention of acidic and basic stain when acetone is used as a decolorizer, it is shown that acidic decolorizers shift the experimentally detd. value. Thus basic decolorizers show abnormally high decolorizing power toward smears stained with acid dyes, and acid decolorizers show the same abnormal behavior toward smears stained with basic dye. By basic decolorizer is meant not one of high p_H value, but one which will form a salt with acids, as, for example, pyridine or aniline. This indicates an ionic chem. equil. as a factor in the mechanism of staining. C. R. F.

Certain factors influencing the staining properties of fluorescein derivatives. H. J. CONN AND W. C. HOLMES. *Stain Tech.* 3, 94-104(1928); cf. *C. A.* 21, 1287.—The behavior of certain fluorescein dyes (eosin, erythrosin, phloxin and rose bengal) in staining *bacteria in dried films of soil* was investigated. These dyes are ordinarily purchased in the form of di-Na salts and are indifferent staining agents for the purpose named. If there be added to the dye soln. a small quantity (0.001 to 0.1%) of a mineral salt of Ca, Al, Mg or Pb, the intensity of staining is greatly increased. The effect of such addn. is to convert the dye partly into a salt of the metal added, which in nearly every instance is relatively insol. and is in every case less sol. than the di-Na salt. Practically identical results can be obtained if the staining be performed with a suspension of the Ca, Al or Pb salt of one of these dyes, although very little of the dye goes into soln. Theories to account for the phenomenon are discussed, including in particular the soln. and absorption theories of staining. The evidences seem to favor the former, although not entirely disproving the latter. C. R. FELLERS

The preparation, by the bacterium of sorbose, of a new reducing sugar with seven carbon atoms. GABRIEL BERTRAND AND GEORGES NITZBERG. *Bull. soc. chim.* 43, 663-7(1928).—See *C. A.* 22, 2178. E. H.

The effect of hydrogen-ion concentration on the bacterial content of gelatin. A. C. FAY. *J. Dairy Sci.* 11, 313-24(1928).—A study of 34 samples of gelatin failed to reveal any relation between the reaction and the bacterial count. The bacterial counts ranged from less than 5 per g. to 20,000, and the reactions between p_H 4.8 and 6.6. The keeping quality test failed to check with the relative bacterial counts. The high acidity of some of the samples had a marked deterring action on the rate of growth of the microorganisms, but in no case did the reaction completely inhibit growth where a mixed microörganic population was added. Gelatin, contaminated in the drying alleys and having a high acidity, would show very little growth. On the other hand a nearly neutral reaction would show growth. In interpreting a low bacterial count of gelatin, one of the factors to be taken into consideration is the reaction. A low bacterial count is believed to be a fairly good index to gelatin of good sanitary quality, although the factors affecting bacterial destruction and growth, such as acidity, must be taken into consideration. J. C. JUKKJENS

Recent methods of investigating lactose-fermenting organisms as applied to Indian conditions. II. J. CUNNINGHAM AND T. N. S. RAGHAVACHARI. *Indian J. Med. Research* 14, 41-5(1926).—"The percentage of the high-ratio group (methyl red-neg., Voges-Proskauer reaction-positive) found in samples of soil varies according to the depth at which the sample has been taken. In samples of milk taken under sanitary conditions the proportion of the high- to the low-ratio groups is in the ratio of 42:58." The slow sand filtration process is most effective in bringing about a reduction in the high-ratio group. FRANCES KRAHOW

Disinfectant action. II. Relations of phenols and amines to proteins. E. ASHLEY COOPER AND JOHN MASON. *J. Phys. Chem.* 32, 868-75(1928); cf. *C. A.* 21, 846.—The distribution of several disinfectants (picric and sulfosalicylic acids, $EtNH_2$, $C_6H_5NH_2$, $(NH_2)_2H_2O$, $NH_4OH.HCl$) between H_2O and dissolved or suspended gelatin and albumin was detd. in an attempt to correlate germicidal activity with soly. or adsorption of the substances used. With coagulated albumin there was noted a rough

parallelism between bacterial action and soly. or adsorption, although no such correspondence occurred with the dissolved proteins. This seems to be contrary to the relationship between disinfectant action and the state of proteins in the cell. W. D. L.

The influence of certain amino acids on cultures of diphtheria bacilli. SBARSKII AND Z. YERMOLYEVA. Biochem. Inst. des Commissariats, Moscow. *Z. Immunitäts.* 54, 105-9(1927).—Previously the authors have shown that amino acids, especially tyrosine, inactivated diphtheria toxin. They now show the effects on the bacteria. Small doses of amino acids in cultures do not kill the bacteria. Tyrosine markedly weakens the toxicity of small toxicogenic cultures of diphtheria bacilli when injected subcutaneously. With toxic strains the effect is minimal. Alanine, leucine and glycine have no such action. Tyrosine in 0.5% concn. in cultures lessens the production of toxin 10 to 20 times. JULIAN H. LEWIS

Bacteriolysis of tubercle bacilli. M. P. ISABOLINSKII AND V. I. GITOVICH. Bakteriolog. Staatsinst., Smolensk. *Z. Immunitäts.* 54, 285-91(1928).—The incubations of tubercle bacilli for several months with various kinds of fatty substances brought about a lipolysis in the organisms. The virulence was so markedly reduced that the cultures were used successfully in a few expts. as a vaccine. JULIAN H. LEWIS

The resistance of bacteriophage to hydrocyanic acid. W. BORCHARDT. Inst. für Schiffs- und Tropenkrankheiten, Hamburg. *Z. Immunitäts.* 54, 403-8(1928).—HCN kills bacteria but does not destroy enzymes. Since it does not destroy bacteriophage the latter is believed to be an unorganized enzyme. JULIAN H. LEWIS

The term iron-organism. EINAR NAUMANN. Lund Univ., Sweden. *Ber. deut. botan. Ges.* 46, 135-40(1928).—The physiology of iron-organisms is too little understood to serve as a basis for classification. For the present the organisms are grouped according to ecological and morphological considerations. All organisms which can ppt. or dissolve Fe should be included. LAWRENCE P. MILLER

Iron-organisms and the formation of lake ore deposits. Certain fundamental aspects of this question. EINAR NAUMANN. Lund Univ., Sweden. *Ber. deut. botan. Ges.* 46, 141-7(1928). LAWRENCE P. MILLER

So-called iron-organisms and the Naumann method for their investigation. N. CHOLODNII. *Ber. deut. botan. Ges.* 46, 317-23(1928).—A criticism of Naumann (cf. preceding abstrs.). The term Fe-organism should be restricted to organisms which respire FeO. LAWRENCE P. MILLER

The viability of bacteria in antiseptic solutions. WM. BULLOCH. Univ. of London. *Centr. Bakt. Parasitenk., I Abt.* 106, 21-9(1928).—Fairly extensive expts. indicate that many reputed disinfectants practically fail when they have to operate on an org. material like catgut, which is exceedingly difficult to penetrate. If properly applied I always sterilizes catgut. JOHN T. MYERS

Bases for the living nature of the bacteriophage. CARL LAUSNITZ. Univ. of Breslau. *Centr. Bakt. Parasitenk., I Abt.* 106, 300-13(1928).—Its variability and its power to become resistant to injurious agents, as chloramine, are best explained by the hypothesis that the bacteriophage is a living organism, not a simple chem. agent. JOHN T. MYERS

Bacteria as a source of ultra-violet rays. M. A. BORON. Univ. of Moscow. *Centr. Bakt. Parasitenk., II Abt.* 73, 373-9(1928).—*B. anthracoides*, *Sarcina flavus* and *B. coli* produce ultra-violet rays as shown by the increased no. of germinating eyes in tubers and increased rate of growth of yeast. JOHN T. MYERS

Sulfate reduction by bacteria with cellulose-fermentation products as a source of energy. L. RUBENTSHIK. Odessa Scientific Inst. *Centr. Bakt. Parasitenk. II Abt.* 73, 488-95(1928).—Sulfate-reducing bacteria, *Microspora*, were isolated from slime of the Kujalnizki liman at Odessa, in the Omelianski medium for CH₄ formation. They form H₂S. The source of C was products accompanying CH₄ fermentation of cellulose, acetic and butyric acids. These organisms are halophiles, the optimum NaCl concn. being 5 to 7%. Metabolism can continue up to 20% NaCl. Sulfate reduction can occur in the absence of NaCl. JOHN T. MYERS

Vitamin effects in the physiology of microorganisms. C. H. WERKMAN. Iowa State College, Ames. *J. Bact.* 14, 335-47(1928).—The addn. of vitamin B to Ashbey medium exerts no stimulation of the rate of reproduction of *Asotobacter chroococcum* or *Rhizobium leguminosarum*. Vitamin B concentrates (Harris) do stimulate them purely because of the addn. of nutrients other than vitamin B. Until further knowledge is at hand the term vitamin should be restricted to those substances not carbohydrates, fats, proteins or minerals, which are essential to growth and reproduction of suitable animals. The term cannot at present justifiably include substances necessary for the

growth and reproduction of microorganisms and certainly not to any substance serving to stimulate growth or reproduction.

JOHN T. MYERS

Investigations of the inhibitory effect of metal salts. I. Silver salts. P. H. ANDRESEN. *Dansk Tids. Farm.* 1, No. 16, 471-89 (1927).—Earlier expts. have only measured the amts. of Ag salts necessary to inhibit bacterial growth. In this expt. the Ag concn. was measured to det. the significance of that quantity, and also to discover what dets the large amt. of Ag salts which must be added. The Ag ion was measured electrometrically. First it was shown that Ag salts react with peptone leaving only a few Ag ions remaining in the soln. The Ag-ion concn. never reached a definite value but decreased continually. Some of the Ag taken up by the peptone was liberated again, although very slowly. Obviously media contg. peptone media could not be used. On the other hand the "Mineral" culture media was unsuited, since the amts. of Ag sufficient to produce inhibition of growth are so small that the Ag-ion concn. cannot be accurately measured. By the addn. of $\text{Na}_2\text{S}_2\text{O}_3$ to a media contg. AgNO_3 , a definite Ag-ion concn. is obtained which is detd. by the ionization const. of $\text{NaAg}(\text{S}_2\text{O}_3)_2$. This concn. remains const. even after long standing. The Ag-ion concn. necessary to inhibit bacterial growth was 0.16×10^{-11} (for *B. coli*). Expts. show that Ag-ion concn. alone is the governing factor of the growth inhibition. The explanation is: (1) There must be a Ag-ion concn. in the medium great enough to react with the bacteria to a sufficient extent. (2) There must be present an amt. of Ag which within a certain time can be taken up by the bacteria. This amt. is larger than (1). (3) If not all the Ag is present in the ionized state, a sufficient quantity has to be present to fulfill conditions (1) and (2). This quantity of Ag salts is detd. directly in inhibition expts. **II. Silver salts.** *Ibid* 2, 57-65 (1928).—It was shown that the explanation regarding the growth inhibition produced by Ag salts is also valid when the growth takes place in the usual broth of the lab. (1% peptone). The const. and well-defined Ag ion concn. was obtained by adding AgNO_3 and a certain excess KI, thus having KI and colloidal AgI simultaneously present in the medium. A very concise method for obtaining the required Ag-ion concn. is given. The Ag ion was measured electrometrically. The expts. have shown that the min. concn. necessary here to produce growth inhibition had a value very close to that which was found with mineral media. The value found for *B. coli* was 0.6×10^{-11} . The same min. concn. was found for *B. typhi*. Also in *Centr. Bakt. Parasitenk., I Abt* 107, 392-7 (1928).

O. A. NELSON

Bactericidal action of dyes. A. PHILIBERT AND J. RISLER. *Compt. rend.* 186, 1583-4 (1928).—Defibrinated human blood samples contg. diphtheritic, streptococcic, colibacillic and staphylococcic cultures, resp., were irradiated for long periods when in no case was there a complete destruction of the organism, and only the staphylococcic culture was hindered in development. On the other hand, if the blood was sensitized by the addn. of 1 in 50,000 of methyl violet a rapid lysis of the organism followed and on irradiation of the blood thus sensitized an even more rapid destruction of the organism occurred.

L. W. RIGGS

Comparative study of the action of urea and thiourea on the growth and vitality of bacteria. E. NICOLAS AND J. LEHDUSKA. *Compt. rend.* 186, 1767-9 (1928).—Thiourea has a definite and more marked inhibitory action than urea on the development and vitality of the pathogenic organisms examd. This action is similar but less intense than that of thiourea on the higher plants (cf. E. and G. Nicolas, *C. A.* 19, 2513). With animals urea is more toxic than thiourea. The reverse is true with plants and microorganisms.

L. W. RIGGS

Influence of the p_H in staining by the Giemsa method. J. G. LACORTE. *Compt. rend. soc. biol.* 98, 1579-80 (1928).—In the study of blood smears of the guinea pig infected with *Trypanosoma gambiense* the preferable p_H of the dye solvent was 7.4.

L. W. RIGGS

Infertilizing power of certain cyclic and aliphatic terpenes against homogeneous cultures of the bacilli of human tuberculosis. P. COURMONT, A. MOREL AND I. BAY. *Compt. rend. soc. biol.* 99, 75-6 (1928), cf. *C. A.* 21, 2007, 3928.—The infertilizing power of long-chain alcs. of the terpene series is particularly noted.

Seasonal changes in conifer leaves, with reference to enzymes and starch formation. J. DOYLE AND P. CLINCH. *Proc. Roy. Irish Acad.* 37, 373-414 (1927).—The disappearance of starch from conifer leaves during the winter is assocd. with various tissue changes and in particular with a decrease in the activity of certain carbohydrate-splitting enzymes. B. C. A.

Does methylene blue penetrate living cells? MARIAN IRWIN. *Nature* 121, 939 (1928).—I. reiterates her former conclusions (*C. A.* 21, 3384) that the blue dye found in the vacuole of cells of *Valonia* after exposure to methylene blue is trimethylthionine, probably present as an impurity in the methylene blue and that the latter dye does not penetrate living cells of *Valonia* F. A. CAJORI

Carbon dioxide release and oxygen absorption by germinating seed. GEORG FRIETINGER. *Flora* 22, 167-201, 2 figs (1927).—F. studied the respiration of seed of peas, wheat, flax, oats and sunflower during the first 3 days of germination in still and moving air and still and flowing water, with coats intact and removed. Respiration is dominantly intramol. in early stages of germination due to coats and structures below hindering movement of O to respiring parts as well as that of CO₂ from them. In oats the glumes play a similar role. As germination progresses these parts are modified and finally broken so that normal respiration becomes dominant. Water increases the effectiveness of these structures in inducing intramol. respiration. Removal of coats greatly favors gaseous exchange and normal as against intramol. respiration. Intramolecular respiration is marked by a high respiratory quotient, which falls as respiration changes from intramol. to normal. The values of this quotient are surprisingly high; in the pea, in early stages of germination, even in air they run as high as 5.3. In flax, a fatty seed, values are 1.9-0.8. Previous authors have found values of about 1 for starchy seed and 0.6 to 0.8 for fatty seed. W. CROCKER

Relation of tuber maturity and of storage factors to potato dormancy. J. T. ROSA. *Hilgardia* 3, 99-124 (1928).—Although the cause of dormancy in potatoes is not definitely known, it is believed that its continuance is due largely to lack of O in the internal tissues. In Calif. seed potatoes are often planted before the tubers have lost their dormancy and thus often fail to sprout and decay occurs. Results show that the more nearly mature potato tubers are when harvested, the shorter is the dormant period. Emergence from dormancy is a gradual, not a sudden, change and is uninfluenced by cold storage or humidity. Twenty references are appended. C. R. FELLERS

Some observations on physiological diseases in apples in British Columbia. H. R. McLARTY. *Sci. Agr.* 8, 636-50 (1928).—The 3 common physiol. diseases are die-back, drought spot and corky core. Search for specific pathogens proved fruitless. Most of the growth in apples occurred at night, an actual loss sometimes occurring in the day. The responsible factor for these diseases appears to be that drought during the late summer and autumn causes excessive killing of rootlets. Super-moisture acts in much the same way. Hence there results a lack in balance in the manu. of the food in the tissues of tree or in the limb above the affected root area. If this lack of balance in the food supply exceeds the degree of tolerance allowed by nature for normal development, then a pathological condition is produced in the developing buds which are just in their formative period. The buds are unable to recover later even though the food supply be ample and normal. This pathological condition is passed along to the developing fruit as corky core or drought spot. C. R. FELLERS

A physiological study of the effect of light of various ranges of wave length on the growth of plants. H. W. POPP. *Am. J. Botany* 13, 706-36 (1926); *Expt. Sta. Record* 58, 124.—In an investigation to det. the effect on plants of removing definite regions of the spectrum in the blue-violet end, several widely different varieties of plants were grown in 5 sep. greenhouses so constructed that practically all conditions except the quality of light could be kept alike in all houses. General observations were made on vegetative vigor, flowering and fruiting. The height was measured weekly, chem. analyses and microchem. tests were made, and anatomical changes were followed in some cases.

The results obtained are detailed for the different wave lengths. The results as a whole indicate that, while ultra-violet rays are not indispensable, the blue-violet end of the spectrum is necessary for normal, vigorous growth of plants. H. G.

Factors influencing the p_H equilibrium known as the isoelectric point of plant tissue. W. J. YOUNG AND F. E. DENNY. *Am. J. Bot.* **13**, 743-53(1926); *Expt. Sta. Record* **58**, 122.—In making use of the method of detg. isoelec. points for plant tissue which consists in placing pieces of the tissue in a series of buffer solns. of varying H-ion concn and noting the p_H value of the buffer at which no change in reaction occurs, it was found that this equil. p_H with a no. of plants was the p_H of a water ext. of the tissue in contact with water instead of buffer soln. for the same time under the same conditions. Most of the effect upon the buffer soln. was not due to absorption of ions from the buffer by the tissue, but was caused by substances leaching out of the tissue into the buffer. The sol. substances which leached out of the tissue and which exerted a dominant effect in changing the reaction of buffers in content with the tissue dialyzed readily through collodion, were not coagulated by heat and were sol. in acid alc. This shows that proteins or other colloidal substances do not play an important role in causing the change in p_H . "Since the tissue itself is not mainly involved, and since the effect produced is not due to proteins or other amphoteric colloids, it is thought that this method does not give reliable information as to the p_H value of the isoelec. point of a tissue or furnish satisfactory evidence of the existence of such a point." H. G.

The germination of century old and recently harvested Indian lotus fruits, with special reference to the effect of oxygen supply. I. OHGA. *Am. J. Bot.* **13**, 754-9(1926). *Physiol. Abstracts* **12**, 590.—Fruits of *Nelumbium nucifera* which had lain buried in a peat bed probably for more than 200 years showed about 100% germination after treatment with H_2SO_4 to render the fruit coats permeable to water. Germination took place well in 100% O, N, H or CO_2 . An internal supply of O was available through the air contained in a cavity inside each fruit and in intercellular spaces. Each fruit contained about 0.2 cc. of gas, which contained on the av. in old fruits 18.33% O, 0.74% CO_2 and 80.93% N; and in young fruits 18.88% O, 0.81% CO_2 and 80.31% N. H. G.

Influence of the concentration of hydrogen ions in water of imbibition on the germinative energy of cereal seeds treated by the Jensen (hot water) method. L. PETRI. *Bol. Staz. Patol. Veg. [Rome] [n. ser.]* **6**, 161-71(1926); *Expt. Sta. Record* **58**, 214.—The data are tabulated, with discussion. H. G.

The physiology of organic acids in green plants. I. Reciprocal relations in nitrogen and oxygen changes in *Begonia semperflorens*. W. RUHLAND AND K. WETZEL. *Z. wiss. Biol., Abt. E, Plantu, Arch. wiss. Bot.* **1**, 558-64(1926); *Expt. Sta. Record* **58**, 212.—An outline is given of the formation of NH_4 and of oxalic acid, of the influence of N-contg. and N-free nutrients on oxalic acid content, and of the daily variations in N and O metabolism. II. Daily variations and otherwise conditioned changes in the content of several organic acids in green plants. H. ULLRICH. *Ibid* 565-8.—Details are given of studies with *Anemone nemorosa*, *Rubus idaeus*, *B. semperflorens*, *Lactuca sativa* and *L. virosa*. H. G.

Recent advances in science: Plant physiology. WALTER STILES. Univ. of Reading. *Science Progress* **23**, 50-5(1928).—Review of recent work on permeability and related questions. JOSEPH S. HEPBURN

Pigment types and their significance in the anthocyanin question. THEODOR LIPMAA. Tartu Univ., Estonia. *Ber. deut. botan. Ges.* **46**, 267-77(1928).—The assimilatory organs of over 300 species of plants were examd. microscopically for anthocyanin at 3 periods during their development. Plants could then be classified into types according to whether their assimilatory organs contain anthocyanin, or if not, whether they can form it under proper conditions, at each of these 3 periods. The data thus obtained cannot be brought into harmony with the idea of Noak (cf. C. A. **18**, 1139) that the system flavonol-anthocyanin plays an important role in CO_2 assimilation. Fall coloring of leaves and anthocyanin as a protective agent against excessive illumination are also discussed. LAWRENCE P. MILLER

A bluish-pigment in the roots of the plane tree. R. SCHARDE. Institute of Plant Physiology, Breslau. *Ber. deut. botan. Ges.* **46**, 298-300(1928).—The lower stem and the roots of a *Platanus acerifolia* cut in December contained large amts. of a bright red coloring matter, found mostly in the medullary rays and to a less extent in the wood parenchyma cells. This pigment is easily soluble in Me, Et, and Pr alc., and gives a tannin reaction with ferric chloride; when dissolved in water contg. a little KOH the color changes to a reddish brown. Roots obtained from another tree in April did not contain any of the pigment. LAWRENCE P. MILLER

Role of iron in the formation of chlorophyll. T. N. GODNEV. *Bull. polytech. inst. Ivanovo-Vosnesensk.* 1927, No. 10, 87-92.—Conforming to expts. of Pollacci and Oddo (cf. C. A. 10, 624) the role of Fe in the production of chlorophyll consists in bringing about the formation of an intermediate compd. of the type of Mg. salt of α -pyrrole-carbonic acid. G.'s investigation, however, confirms Deuber's findings (cf. C. A. 21, 3218) according to which the Mg. salt of α -pyrrolecarbonic acid in the absence of Fe not only does not aid the disappearance of chlorosis of leaves, but is even noticeably harmful.

BERNARD NELSON

Studies on glutelins. IV. The glutelins of corn (*Zea mays*). D. BREESE JONES AND FRANK A. CSONKA. U. S. Dept. of Agr. *J. Biol. Chem.* 78, 289-92(1928); cf. C. A. 22, 253.—Corn meal was extd. with alc. NaOH. Glutelin was pptd. from this ext. by adding HCl to p_H 6.7-6.8. The ppt. was redissolved in aq. NaOH and α -glutelin pptd. by adding $(NH_4)_2SO_4$ to 3% of satn. β -glutelin was obtained from the supernatant liquid by pptg. with $(NH_4)_2SO_4$ at 16% of satn. The isoelec. point of α -glutelin was 6.45. Detn. of N distribution gave the following percentages: amide N 7.73, cystine N 2.04, arginine N 15.11, histidine N 2.81, lysine N 7.99, amino N in filtrate from bases 59.64.

C. RIEGEL

Maturing of peas. LASAUSSE, GUÉRITHAULT AND PELLERIN. *Bull. sci. pharmacol.* 35, 337-45(1928); cf. C. A. 19, 1442; 20, 2546; 21, 1315.—Peas were collected at different dates and on one date at different heights on the vines, making in all 5 samples which were analyzed when fresh, after the usual cooking and when dried. The results are tabulated and the ratios cellulose/dry ext., cellulose/total N, starch/dry ext., starch/total N, starch/cellulose and dry ext./total N are discussed. Further work is in progress.

L. W. RIGGS

Influence of sodium carbonate and calcium chloride on the acidity of the juice of *Zea mays*. I. L. KARASIEWICZ. *Bull. soc. chim. biol.* 9, 841-50(1927); 10, 702-13(1928).—Corn plants were grown in a medium contg. $Ca(NO_3)_2$ 0.3192 g., K_2HPO_4 0.5, $MgSO_4$ 0.1, $FeSO_4$ 0.05, $MuCl_2$ 0.025, $ZnSO_4$ 0.02, K_2SiO_3 0.025, $CaCO_3$ 1.0, NaF 0.000002, $Al_2(SO_4)_3$ 0.00001, $Na_2B_4O_7$ 0.000004, KI 0.000002 and H_2O one l. To this medium was added either Na_2CO_3 or $CaCl_2$ in different amts. The p_H was detd. at the beginning of the culture, before and after the addn. of Na_2CO_3 or $CaCl_2$ and on the day of gathering the plants. The plants were washed, dried and analyzed for the usual vegetable acids. The addn. of Na_2CO_3 to the nutritive medium in which corn is growing lowers the total acidity of the plant and this diminution occurs in the acids insol. in water and fixed with Ca. The addn. of $CaCl_2$ to the medium increased the total acidity in proportion to the Ca added. The increase in acidity occurred in acids combined with Ca. In the change of acidity by the addn. of either Na_2CO_3 or $CaCl_2$ the quantities of free or combined acids which are sol. in water were not affected. The sol. Na salts are more readily excreted by the roots and the nocturnal excretions of the leaves, while the Ca salts are fixed in the plant as oxalate. The presence of 0.1 g. Na_2CO_3 or 2 g. $CaCl_2$ per l. in the nutritive medium hinders the growth of the corn plant.

L. W. RIGGS

Variations of calcium oxalate in certain grafted plants. LUCIEN DANIEL. *Compt. rend.* 186, 1143-4(1928).—The histologic examn. of the swellings at grafted points of Solanaceae, also in *Cannabis* and *Mercurialis*, shows the presence of gritty crystals of CaC_2O_4 , which are more numerous and better developed in the wounded portions where cell multiplication is most active.

L. W. RIGGS

Physiologic role of the pyrocatechol tannins. MICHEL-DURAND. *Compt. rend.* 186, 1145-7(1928); cf. C. A. 22, 1792.—The tannins of branches of *Aesculus hippocastanum* and of tubers of *Rumex hymenosepalus* were studied. The distinction of phlobatannins into compds. sol. and insol. in acetone is of minor importance because of the slight quantity of insol. tannins in tissues contg. no chlorophyll. These 2 kinds of compds. behave like starch, and appear to be utilized during the beginning of the formation of swellings and tubers. The tannins may be considered as plastic foods.

L. W. RIGGS

Influence of the host on the morphologic characters of the polypore of the birch. Antioxygenating role of tannin. L. LUTZ. *Compt. rend.* 186, 1231-2(1928); cf. C. A. 21, 3070.

L. W. RIGGS

Conditions for the liberation of free iodine in the laminaria. PIERRE DANGEARD. *Compt. rend.* 186, 1371-3(1928); cf. C. A. 22, 1993.—Cutting or bruising the tissue of the plant, or immersing the plant tissue in acid or alc. favors the liberation of free I.

Hypotonic condition of cells affected with mosaic disease. J. DUFRÉNOY. *Compt. rend. soc. biol.* **98**, 1499-1500(1928).—A cytologic study.

L. W. RIGGS

Osmotic value of plant cells in cultures. M. THIELMAN AND L. BERZINE. *Compt. rend. soc. biol.* **99**, 87-9(1928).—Cytological.

L. W. RIGGS

A new type of acid carbohydrate from sea weed. LEONARD H. CRETCHER AND WM. L. NELSON. *Science* **67**, 537-8(1928).—From *Lamanaria agardhii*, collected at Woods Hole, Mass., an acid was extd. by dil. Na_2CO_3 and pptd. by HCl. The formula was $(\text{C}_6\text{H}_8\text{O}_6)_n$. The compd. loses 24.5% of its wt. as CO_2 on boiling with dil. HCl. An acid was isolated from *Macrocystis pyrifera* (giant kelp) from the Pacific coast. This acid is also a polyuronic anhydride to the extent of at least 98.6%.

L. W. RIGGS

A study of the catalase of the fruits of pear varieties. E. L. OVERHOLSER. Univ. of Calif. *Am. J. Botany* **15**, 285-306(1928).—The O evolved by the catalase of pear pulp was almost directly proportional to the quantity of H_2O_2 used. Increasing the amt. of pear pulp increased the O evolved from a given quantity of H_2O_2 , but the relative increase was not as great as when the amt. of H_2O_2 was increased. The addition of increasing amts of H_2O reduced the O evolved within a given period of time. Boiling the pear pulp for 15 min. destroyed the catalase activity. The varietal catalase activities and p_{H} of the pulp of 10 varieties of pears were studied and high p_{H} values appeared to coincide with high catalase activities. With the varieties Louise, Clairgeau, and Fox, when the p_{H} of the reacting pulp was reduced to approx. 3.55 by the addition of 0.1 N HCl, the catalase was almost completely checked. As the p_{H} was raised by the addn. of 0.1 N NaOH the catalase activity increased to a max. with a p_{H} of from 6.00 to 6.50. This indicated that with pear pulp the max. activity was slightly on the acid side rather than at neutrality or under slight alk. conditions such as would be effected by the addition of excess CaCO_3 . Freezing at -10° for 2 months greatly decreased the catalase activities as compared with storage at 0° . The effect of the storage temp. upon catalase activity depended upon the duration of the storage period, which varied with the temp. Storage at -12° and 40° for 8 days increased the catalase activity, but the activity decreased with 14 and 22 days' storage. Storage at 0° and 30° resulted in a gradual increase in catalase activity throughout the storage period of 22 days. Storage at 20° gave a slight increase in catalase activity after 8 days' storage, and then a gradual falling off after 14 and 22 days. Storage at 7.5° resulted in a continuous decrease throughout the storage period of 22 days. The av. p_{H} value tended to be higher at the storage temps. resulting in catalase increase and lower where the catalase decreased.

J. J. SKINNER

Chemical treatment for shortening the rest period of pot-grown woody plants. F. E. DENNY AND E. N. STANTON. Boyce Thompson Inst., Yonkers, N. Y. *Am. J. Botany* **15**, 327-36(1928). **Localization of response of woody tissues to chemical treatments that break the rest period.** *Ibid.* 337-44. —Individual twigs of dormant lilac plants growing in pots were exposed to vapors of ethylene chlorohydrin, ethylene dichloride, and ethyl iodide, while similar twigs upon the same plant received no chem. treatment. The treated twigs started growth but the untreated twigs remained dormant. The sep. twigs on a given plant acted as units, and any one of them could be aroused from the rest period while adjacent twigs were inactive. Likewise, individual buds upon twigs were exposed to vapors of ethylene chlorohydrin under suitable conditions, and were forced into growth by this treatment, while the bud upon the opposite side of the twig received no treatment and remained dormant. Of the 2 buds at the tips of twigs of lilac either one could be caused to develop new twigs without breaking the dormancy of the other bud of the pair. Dormancy in the lilac is not systemic, that is, distributed throughout the plant. It is localized in the buds only. The roots, bark, and conductive tissues are not dormant, but are able to supply sap to the buds as soon as the buds are able to use it. The expts. indicate that, in studying the dormant period, evidence of changes accompanying the resumption of growth should be sought first of all in the buds themselves, and not in the surrounding storage tissue.

J. J. SKINNER

The hydron concentration of plant tissues. IX. Improved technic for the range indicator method (R. I. M.). C. TERENCE INGOLD AND J. SMALL. Queen's University, Belfast. *Protoplasma* **3**, 458-68(1928); cf. *C. A.* **21**, 2721.—The results of the present investigation indicate that when indicator solns. contg. more than 10% alc. are used without diln. with distd. H_2O in observations by the R. I. M., outward diffusion of electrolytes may lead to a mixing of diffusible substances remotely approaching the con-

ditions obtained when expressed sap is used for the detn. of the p_H of plant juices. Therefore the R. I. M. technic may be improved by: the use of standard alc. indicators only after diln. with fresh cond. H_2O to bring the alc. content to or below 10%; the use where possible of aq. indicators; the reduction of the period of immersion to a min. consistent with the obtaining of unequivocal color indications; the use of all indicators with the indicator brought as near as possible to its neutral point, so that even a slightly buffered plant fluid may be able to throw the indicator to one side or the other of the neutral point.

M. H. SOULE

Nitrogenous metabolism of *Pyrus malus* L. IV. The effect of sodium nitrate applications on the total nitrogen and its partition products in the leaves, new and one-year branch growth throughout a year's cycle. WALTER THOMAS. Penna. State College. *Plant Physiology* 2, 245-71 (1927); cf. *C. A.* 22, 1994.—Two Stayman Winesap trees of the same age growing in sod on a homogeneous soil were used. One of these trees was treated in two applications with 20 lbs. of $NaNO_3$ and the other left untreated. The period of most rapid absorption of the NO_3 ion is characterized by a large increase in the total water-sol. and non-protein N, concomitant with which is an increase in the amino, amide, basic and "rest" N fractions of the tree receiving N as compared with the control. A comparison of the total water-sol. N, the non-protein N and also of the amino N fraction in the two trees definitely shows that the first application of $NaNO_3$ at the end of April took 3 weeks to reach the one-year branch growth; but that the absorption and translocation of NO_3 ions of the second application in the early part of June is 3 times as rapid as in the earlier period. N is stored in the fall, as amide N and "rest" N compds., chiefly in the one-year branch growth, and this storage is much higher in the fertilized tree. A much higher plane of N metabolism is indicated in the N-treated tree. The importance of the need for further knowledge of the functions of the "rest" N compds. is pointed out. Methods of fractionation and complete analytical data and graphs are given.

WALTER THOMAS

Relation of composition to growth and fruitfulness of young apple trees as affected by girdling, shading, and photoperiod. R. H. ROBERTS. Univ. of Wisconsin. *Plant Physiology* 2, 273-86 (1927), cf. *C. A.* 20, 3485-6.—One hundred Wealthy trees grafted on standard seedling stocks were subjected to the different environmental conditions stated in the title. In addn. to growth measurements and anatomical studies on the stem new growth, the chem. compn. with respect to N and various carbohydrate fractions of the new growth and two-year branch growths were also detd. None of the external factors imposed had a consistent effect upon the compn., growth character or fruitfulness of the trees. Although girdling checked growth and induced fruiting, the shading of girdled trees annihilated the effects of girdling, giving growth typical of ungirdled, unshaded trees. Short-day trees growing without added N grew and blossomed like long-day N-treated trees. Growth character, including blossom bud formation, is primarily dependent upon internal compn. and secondarily upon external environment. Chemical analyses as developed at present provide only a limited means of measuring the responses of the trees to the various external environmental factors.

WALTER THOMAS

Preliminary examination of the corolla of *Monarda punctata*. H. G. HEWITT. *J. Am. Pharm. Assocn.* 17, 457-8 (1928).—Florets were collected in 1924. H_2O was detd. by the xylene method. Yields were 68.7 and 69%. According to the Fluckiger test thymol and carvacrol were absent. Total ash was 10.8%, insol. ash 5.88%; volatile oil 4-4.5%; $d_{20} 0.9652$; hydrothymoquinone was not found.

PHILIP B. HAWK

Vitamin B. C. FUNK. *XII Int. Cong. Physiol.* 1926, 58.—A mixt. of naphthol-yellow-S and Ag picrate ppts. the greater part of vitamin B, most of the other nitrogenous substances remaining in soln. Vitamin B appears to be separable into 2 fractions

B. C. A.

Avitaminosis and metabolism. A. PALLADIN. *XII Int. Cong. Physiol.* 1926, 123-4.—Metabolic disturbances due to avitaminosis and hunger, resp., are distinct; the differences observed are described.

B. C. A.

Substances with a vitamin action in the common garlic (*Allium sativum* L.). G. PARRINO AND A. DOMINICI. *Ann. igiene* 37, 1-8; *Chem. Zentr.* 1927, I, 3204.—Biol. tests of animals rendered it certain that vitamins B and C are present in garlic. Heat-

ing to 130° destroys these vitamins. The presence of a vitamin D or a substance with a similar action is very probable. The juice of the garlic contains other compds. which promote fermentation and cellular respiration. C. C. DAVIS

Basic principles of human nutrition, and an investigation of the dietary habits of 300 individuals of New South Wales with reference to diet and physique. G. Z. DUPAIN. *J. Proc. Sydney Tech. Coll. Chem. Soc.* 3, 37-54(1927).—Dietary records were usually taken for a week or longer. Of the diets examd only 2% indicated some idea of food values and diet planning. Carbohydrate consumption was about 5 times greater than either proteins or fats. Protein and fat consumption was about the same except for 2 classes: those individuals with a calorific intake nearing 2800 cal. consumed much less fat than protein, and those nearing 3600 cal. consumed a far greater amt. of fat. As the body wt. increased the cal. also rose. The highest food consumption was between the ages 13 and 18, all cases of active boys. A great consumption was noted between the ages 34 and 40. The females studied ate less in the majority of cases. RUSSELL C. EBB

Vitamin C in milk. Its relation to concentration, homogenization and sterilization. P. LAVALLE. *Bull. soc. chim. biol.* 9, 208(1927), *Rev. hyg. med. prev* 50, 556-7(1928).—Using dogs as subjects L. found no evidence of scurvy after 15 months with concd., homogenized or sterilized milk as the sole source of vitamin C. The controls were affected with scurvy after 9-10 months. C. R. FELLERS

Studies of protein metabolism, mineral metabolism, and digestibility, with clover and timothy rations. L. A. MAYNARD, R. C. MILLER AND W. E. KRAUSS. Cornell Univ. Agr. Expt. Sta., *Memoir* 113, 1-33(1928).—The results of 6 Ca and P balances with a clover ration and 6 with a timothy ration are presented. Though the Ca balances were negative in all but 1 case, they were nearer to being positive with the clover ration, with its larger content of this mineral element. The P balances were negative in all but two cases, but the losses were less with the ration supplying the larger amts. of this element; that is, the timothy ration, with its larger amts. of P-rich concentrates. The results suggest the desirability of considering the supply of both Ca and P and the ratio between them, in trying to secure a better assimilation of either. There was but little variation in the Ca and P content of the milk, under the conditions studied. The % of P in the milk seemed to increase slightly in response to an increased supply in the feed. A comparison of the observed digestibilities of the exptl rations with their theoretical digestibilities calcd. from av. coeffs show a marked depression from the calcd. values for protein and crude fiber and a slight depression for N-free ext. The results for fat are variable. The depression of the digestibility of the protein was greater in all cases with the clover ration than with the timothy ration. The same relation was apparent for the crude fiber in 2 out of 3 of the expts. No consistent differences were found for the other nutrients. The greater depression of the digestibility of the protein with the clover ration is not to be explained on the basis of a higher output of metabolic N. On the basis of relationships between protein and crude fiber in the two rations, it is suggested that the differences in the depression of digestibility noted were the result of some modifications in the fermentative processes of the digestive tract. A full bibliography is appended. C. R. FELLERS

Food consumption of rural school children in relation to their health. ESTER S. DAVIES. Mass. Agr. Expt. Sta., *Bull.* 241, 98-147(1928).—A field study of the dietary habits of school children. C. R. FELLERS

Diet and cholesterol elimination in the bile. HUGO SOLOMON AND L. SILVA. *Prensa Med. Argentina* 12, 840-4(1926); *Biol. Abstracts* 1, 468; cf. *C. A.* 21, 1295.—In man cholesterol in small quantities is eliminated in the bile (duodenal bucket) when the diet is low in this substance. With increased cholesterol content of the food, the elimination is augmented. The cholesterol balance may be pos. when the food contains 6-7 g. a day. H. G.

Honey contains vitamins. ALIN CAILLAS. *France Apicole* 32, 3-5; 54-5(1926); *Biol. Abstracts* 1, 623.—Definite symptoms of beriberi rapidly disappeared in pigeons when fed honey on polished rice. A ppt. of the vitamin had a similar but more rapid effect. H. G.

Studies in fractionation of the antirachitic vitamin. ELIZABETH M. KOCH AND M. H. CAHAN. *Proc. Inst. Med. Chicago* 1926, 1-4(1926); *Biol. Abstracts* 1, 624.—The antirachitic properties of irradiated and non-irradiated cholesterol, lecithin, oleic and stearic acids, and tyrosine were tested. Of these, cholesterol alone acquired antirachitic properties when irradiated with ultra-violet light. A yellow resinous material, extd. by liquid NH₃ from this irradiated cholesterol, when fed in amts. of 0.2 mg. daily entirely prevented rickets, and was 8-10 times more active. A similar active ext.

from the non-saponifiable fraction of cod-liver oil was made with liquid NH_3 . The Lifschütz and Rosenheim color tests indicated that it is similar to oxycholesterol, but the authors do not claim that it is identical with it. H. G.

Light in the prevention of rickets. F. H. HUMPHRIS. *Phys. Therap.* 19 (9), 497–501(1926); *Biol. Abstracts* 1, 876.—The facts leading to the conclusion that rickets is a light-deficiency disease are: (1) it is a disease or aberrancy of the bony tissues due to, or characterized by, Ca and P deficiency as well as by lack of fat-sol. vitamin A; (2) the ultra-violet ray therapy raises the Ca and P content in the body and also increases the energy of fat-sol. vitamin A. H. G.

Vitamins in green plants. N. BEZSSONOV. *Rev. Path. Vég. et Ent. Agr.* 14, 142–55(1927); *Biol. Abstracts* 1, 1023.—Vitamin A can be obtained from seedlings grown in the dark, but it is much more abundant after the seedling has been illuminated. Vitamin A is more abundant as the tissues are richer in chlorophyll, although it is neither chlorophyll nor carotin. It does not disappear when plants are transferred from the light to darkness. Vitamin A readily absorbs O_2 . It is one of the lipids that can be extd. from green tissues along with chlorophyll, and it may act as a sensitizing agent in respect to chlorophyll. Solns. of chlorophyll become more stable in the light when the accompanying vitamin A has been eliminated. Vitamin A may be extd. by treating 40 cc. of the sap obtained from green tissues with 16 cc. of an 8% soln. of Pb acetate. The ppt. is deposited on a filter, washed with 20 cc. water, and dried in a vacuum. A ppt. of about 0.2 g. can be obtained in that way. This is brought into the form of a powder, to which petroleum ether is added. A treatment of 24 hrs. brings vitamin A into soln. in ether, while chlorophyll is obtained from the ppt. H. G.

Streptothrix corallinus in the estimation of vitamin B. JEAN ORR-EWING AND VERA READER. *Biochem. J.* 22, 440–2(1928).—In testing the more active vitamin B_1 concentrates (0.1-mg. per day pigeon dose), a considerable difference was noted in bacterial growth between flasks contg. $\frac{1}{20}$ and $\frac{1}{40}$ dose, or between those contg. $\frac{1}{400}$ and $\frac{1}{800}$ dose in 20 cc. medium (cf. C. A. 22, 2960). It was then found that, given a fraction, say $\frac{1}{1000}$ part of a vitamin B_1 concentrate, it was possible to predict the number of doses found in the whole. The technic developed has been found capable, with certain limitations, of replacing the pigeon test in following the fractionation of the vitamin. BENJAMIN HARROW

Sterol and antirachitic vitamin. ADOLF WINDAUS AND ALFRED HESS. *Nachr. Ges. Wiss. Göttingen, Math.-physik. Klasse.* 1926, 175–84.—If cholesterol is purified by phys. methods (recrystn.), it retains its ability to become activated by irradiation. If it is purified by chem. methods (formation of derivs. from which it is liberated later on, treatment with mild oxidizing agents) the ability to become antirachitically active after irradiation is totally lost. Conclusion: The activity is due to an impurity which is decompd. during the chem. reactions, and neither cholesterol nor allo-cholesterol is the provitamin. Ergosterol may be the antirachitic provitamin, since it cannot be sepd. from cholesterol by phys. methods, is very sensitive toward oxidation and is active even in mere traces after irradiation. Also it presents an absorption band in the ultra-violet, corresponding to the one observed with active cholesterol. Ergosterol or one of its isomers should be regarded as the true antirachitic provitamin. A. L. H.

Chemical vitamin tests. J. BULIR. *Časopis lékařů českých* 66, 1779–84(1927); *Ber. ges. Physiol. expth. Pharmakol.* 44, 374.—Review of colorimetric tests. Detns. of vitamins A and C by the methods of Caro, Price and Bezssonov check well with biological detns. The colorimetric methods are useful but permit a rapid orientation only. MARY JACOBSEN

Insulin in fattening cures. VITTORIO SCIMONE. *Rass. clin. terap. sci. affini* 27, 108–14(1928).—Six patients in a very poor state of nutrition, suffering from anovarium asthma, asthenia with dyspepsia or intestinal ptosis and atony, pylorospasm, hyperchlorhydria, urticaria and neurosis received insulin, the doses rising gradually from 10 to 45 units a day. Wt., general condition and digestion improved considerably. The basal metabolism, and alkaline reserve were not changed. The asthma was not affected, the urticaria disappeared. With anovarium the pubic and axillary hair became more abundant; that on the *labia majora* became scarce. MARY JACOBSEN

Does oil of capivara contain vitasterol A? RODOLPHO ALBINO DIAS DA SILVA. *Rev. brasil. med. farm.* 3, 422–3(1927).—Machado, *Presse méd.* 1927, 1196, has obtained a positive Fearon test with the oil of capivara. The test is, however, not sp. for vitamin A and S. has failed to find vitamin A in the oil. MARY JACOBSEN

Biological values of certain types of sea foods. III. Vitamins in clams. D. BRESE JONES, E. M. NELSON, J. C. MURPHY AND J. P. DEVINE. *Ind. Eng. Chem.* 20, 648–52(1928); cf. C. A. 22, 1184.—Although oysters are rich in vitamin B, clams

are devoid of it. They contain less vitamin A than oysters. Five g. of hard-shelled clams daily were insufficient for a complete cure of xerophthalmia, while 3.5 g. of soft-shelled clams were barely sufficient to cure. Both varieties were superior to oysters in vitamin D and in factors essential for reproduction and rearing of young. A. L. V.

Acceleration of growth rates by dietary modifications. ALBERT G. HOGAN, JESSE E. HUNTER, AND HARRY I. KEMPSTER. Univ. of Mo. *J. Biol. Chem.* **77**, 431-6(1928).—Supernormal growth may be induced in chicks by feeding them the following ration: whole wheat 55.6, whole milk powder 8.2, com. casein 12.3, alfalfa meal 2.5, butter fat 4.2, NaCl 0.9, CaCO₃ 1.3, cod-liver oil 3.0, and dried yeast 12%. This ration is definitely inferior if either the cod-liver oil or the yeast is omitted. Similar results have been obtained with turkeys. It is not certain that the rapid growth rate was due to the ration alone. Confinement in pens, disinfection of quarters, and avoidance of exposure to cold or wet weather and to drafts may have contributed to the results obtained. Attempts are being made to devise a practical poultry ration that will support supernormal growth but it remains to be seen whether such a ration is of any value under com. conditions. A. P. LOTHROP

Sulfur metabolism and partition of sulfur in the urine of fasting dogs. SERGIUS MORGULIS. Univ. of Neb. *J. Biol. Chem.* **77**, 627-45(1928).—"The av. urinary N:S ratio in dogs on a fairly uniform diet ranges from 16:1 to 29:7. During prolonged fasting these dogs (with only 1 exception) show the same av. ratios. The N:S ratio is, therefore, peculiar to the individual dogs, some having high and others low ratios. The exptl. evidence fails to demonstrate a relationship between the N:S ratio of the food and of the urine. It is impossible to det. from the urinary N:S ratios the nature of the tissue undergoing catabolism. The variations in ethereal sulfate during fasting suggest that this S fraction must be chiefly of metabolic origin. The neutral S fraction is subject to very irregular changes, but the evidence does not permit the conclusion that these are associated with diminished oxidative processes in the fasting organism. The variations in the inorg. sulfate fraction are likewise irregular. This fraction is influenced more by the individuality of the dog than by the diet, some dogs voiding urine with a high % of inorg. sulfate and low neutral S, while others show the reverse condition. Upon feeding, the inorg. sulfates tend to assume the same proportion as before the fast, independently of the changes which this S fraction had undergone in the course of inanition." A. P. LOTHROP

The effects of inadequate vitamin A on the sexual physiology of the female. HERBERT M. EVANS. Univ. of Calif. *J. Biol. Chem.* **77**, 651-4(1928).—"Inadequate vitamin A injures the female reproductive system so that fertilization and implantation often fail. In this respect it differs radically from the reproductive impairment due to low vitamin B content, where, typically, the eggs are always healthy and implantation takes place but resorption follows. A level of inadequate vitamin A can be secured, denoted by continuous cornified cell vaginal smears, during which estrus and ovulation occur and are, in fact, fairly frequent. This is only demonstrable by the continuous presence of the male for no changes occur in the vaginal cell types. Four-fifths of the copulations eventuate in failed implantation. A great many of them fail even to establish the condition of pseudo-pregnancy since another estrus occurs in 5 days. About 1/5 of the copulations leads to the birth of litters. It is interesting that throughout gestation the cornified cell smear continues. Normally the vaginal epithelium in pregnancy is high columnar in type." A. P. LOTHROP

The possible role of aluminum compounds in animal and plant physiology. E. V. MCCOLLUM, O. S. RASK AND J. ERNESTINE BECKER. Johns Hopkins Univ. *J. Biol. Chem.* **77**, 753-68(1928).—"The spectrographic method was used for ascertaining the presence or absence of Al and for the approx. estn. of small quantities thus assuring the absence of all chem. reagents except at O₂. All chances of Al contamination were thus reduced to the lowest possible point. Al is not a constituent of the plant products examd.: wheat germ, yeast, navy bean, lima bean, potato, carrot and cottonseed meal. It is also absent from hens' eggs and the following organs and tissues of the rat: liver, kidney, spleen, testes, ovaries, bone and skeletal muscle. It is present in concns. less than 1 p. p. m. on the hair, intestinal wall and lungs as would be expected. Al compds. are not absorbed out of the stomach or intestinal tract when present in the diet and do not form any union or chem. compd. with the stomach or intestinal walls. In concns. in the diet as high as 600 p. p. m. of the element Al exerts no noticeably deleterious action on growth, reproduction, or general well-being of rats as judged by external appearance and autopsy. These results confirm the views of the Remsen Referee Board of Consulting Experts that the consumption of foods contg. added Al is not deleterious or injurious to health. These conclusions can probably not be regarded as

final until addnl. and confirmatory data have been obtained on a larger variety of materials and animals but until then there seems to be no other alternative than tentatively to accept them.

A. P. LOTHROP

Iron in nutrition. V. **The availability of the rat for studies in anemia.** J. WADDELL, H. STEENBOCK, C. A. ELVEHJEM AND E. B. HART. Univ. of Wis. *J. Biol. Chem.* **77**, 769-75 (1928); cf. *C. A.* **21**, 2017.—Young rats from the stock colony weaned at the age of 3-4 weeks develop a profound anemia after 6-8 weeks subsistence on a diet of whole milk (cow's). The hemoglobin titer is reduced from 10.83 g. per 100 cc. of whole blood to 4 g. or less. Other workers have found it necessary to carry rats into the 2nd generation before anemia appears. The diet of the stock females contains nothing in the way of table scraps or vegetable refuse and the intake of the mixed ration may be reduced because of the presence of considerable whole milk, this may be a primary factor in detg. the amt. of hemoglobin-forming substance with which the young rats are supplied at birth. VI. **Iron salts and iron-containing ash extracts in the correction of anemia.** *Ibid.* 777-95. Inorg. Fe salts (prepd. from pure Fe wire) fed at a level of 0.5 mg. of Fe 6 times a week do not materially increase the hemoglobin level in anemic rats. The ashed residue of dried beef liver, dried lettuce, and yellow corn and acid exts. of these ashes are very effective in curing anemia when fed at a level of 0.5 mg. of Fe under the same conditions. It is evident that the ashes and ash exts. contain in addn. to Fe some other inorg. substance or substances vitally concerned in the synthesis of hemoglobin. VII. **Copper as a supplement to iron for hemoglobin building in the rat.** E. B. HART, H. STEENBOCK, J. WADDELL, AND C. A. ELVEHJEM. *Ibid.* 797-812.—A com. prepn. manufactured from liver for the treatment of pernicious anemia in man cured anemia in rats kept on a whole milk diet supplemented with Fe. The ash of the prepn. was also active and the potent material was pptd. by H_2S from a HCl ext. of the ash. The active agent in the H.S. ppt. was found to be Cu and feeding expts. using $CuSO_4$ showed that rats receiving 0.05 mg. levels of Cu daily in addn. to 0.5 mg. of Fe rapidly recovered a normal hemoglobin content. Those receiving as little as 0.01 mg. showed marked increases with a final return to normal. An improvement in phys. well-being as evidenced by greatly increased appetite, smoother coats, and increased vigor and activity was a pronounced accompanying phenomenon. No evidence was obtained of an org. factor necessary for hemoglobin synthesis. The expts. point to the need for a more intensive study of the role of small quantities of inorg. substances in the diet.

A. P. LOTHROP

Studies on the influence of glucose and dihydroxyacetone on the blood sugar level under variable conditions. KENSUKE UCHIDA. *Biochem. Z.* **194**, 111-27 (1928).—The utilization of glucose in dogs depends upon the previous nutritive régime. Dogs fed a protein-rich and carbohydrate-free diet show certain peculiarities which are observed in totally depancreatized dogs which have become severely diabetic. These peculiarities manifest themselves even more strongly on such a preliminary diet in dogs whose pancreatic ducts have been tied. On the contrary, these conditions have no effect on the utilization of triose, and even totally depancreatized diabetic dogs utilize the dihydroxyacetone though not so well as normal dogs.

S. MORGULIS

The normal blood sugar content of the dog and its physiological variations. KARL SCHWARZ AND HERWIG HÄMP. *Biochem. Z.* **194**, 351-61 (1928).—On a uniform and abundant diet the blood sugar content of the same dog, 12 hrs. after feeding, is remarkably const., the variations being only 0.004-0.006 mg. per 100 cc. The abs. sugar quantities of dogs under uniform nutritive conditions do not vary much. The blood sugar of a well-nourished dog is lowered already after 2 days of fasting. One-sided nutrition, for instance with meat or nearly pure carbohydrate in sufficient amt. to supply the required amt. of energy, has no effect on the blood sugar. Following feeding the blood sugar rises rapidly, reaching a max. between 2 and 3 hrs. and returning to normal in about 12 hrs. The max. values are 28-50% above the normal concn.

S. M.

Comparative influence of lipids and carbohydrates of the diet on the evolution of avitaminosis B. (MME.) LUCIE RANDOIN. *Compt. rend.* **186**, 1438-41 (1928).—Rats receiving a basic diet of casein, fibrin, ovalbumin, butter, salts and glucose lived 22 to 53 days, while rats receiving practically the same diet except that lard replaced the glucose lived 53 to 134 days. Thus in the absence of vitamin B from the diet, fats without glucose appear to restrain the development of polyneuritis better than glucose with only a small amt. of butter fat.

L. W. RIGGS

Influence of diet on the ratios of the elimination of ammonia and the p_H of the urine. MICHEL POLONOVSKI AND PAUL BOULANGER. *Compt. rend. soc. biol.* **98**, 963-5 (1928).—A normal subject was placed on ordinary vegetarian and hypernitrogen diets for periods of 8 days and the ammoniacal coeff. and p_H of the urine were detd.

at 2-hr. intervals on the 8th day. The individual was also subjected to a 2-day fast with 125 cc. of water every 2 hrs. With the ammoniacal coeff. as ordinates and the p_H values as abscissas, 4 hyperbolic curves were constructed. These curves were displaced progressively upwards and toward the right, that is, toward the increased ammoniacal coeffs. and greater p_H values, in proportion as the diet was richer in sugars and poorer in N. The curve of fasting, which is a special case of high N diet, shows even a lower p_H and lower ammoniacal coeff. than the curve for a high N meat diet.

L. W. RIGGS

Dissociation of the factors of growth and antirachitism. È. LESNÉ, ROBERT CLÉMENT AND S. SIMON. *Compt. rend. soc. biol.* **98**, 928-30(1928).—In a study of the action of 4 samples of cod-liver oil on rats it was proved that the potency of the growth factor in a given sample is independent of the potency of the antirachitic factor.

L. W. RIGGS

Action of choline on the nervous phenomena of beriberi of pigeons. MARIE SKARZYNSKA-GUTOWSKA. *Compt. rend. soc. biol.* **98**, 1045-7(1928).—Exts. of vitamin B from wheat bran, when intravenously injected, have an action analogous to that of choline by causing a transitory lowering of arterial pressure. The disappearance of nervous symptoms, or their absence in many cases, accords with an intense mobilization of choline in the organism. Avitaminosis B is caused by the absence of several substances among which is choline.

L. W. RIGGS

Causes of the retention of water after the ingestion of fat. WACŁAW MORACZEWSKI. *Compt. rend. soc. biol.* **98**, 1058-60(1928).—See C. A. **22**, 2592.

L. W. RIGGS

Case of emaciation resistant to fattening treatment by insulin. FERNANDO FONSECA. *Compt. rend. soc. biol.* **98**, 1590-1(1928).

L. W. RIGGS

Comparative study of the elaboration of vitamin B by yeasts cultivated in extract of malt, cane molasses and beet molasses. (MME.) I. RANDOIN AND R. LECOQ. *Compt. rend. soc. biol.* **99**, 47-9(1928).—Pigeons fed a control diet without vitamin B lived 17 to 27 days, with yeasts grown on beet molasses added to the control diet the pigeons lived 18 to 26 days, with yeasts grown on cane molasses 40 to 57 days and with yeasts grown on ext. of malt 65 to 76 days.

L. W. RIGGS

Treatment of pernicious anemia with a high-caloric diet, rich in vitamins. K. K. KOESSLER AND S. MAURER. *J. Am. Med. Assoc.* **89**, 768-74(1927); *Expt. Sta. Record* **58**, 93.—The treatment of pernicious anemia by a "high-vitamin, high-caloric diet, furnishing the meats chiefly in the form of liver, kidney and other edible viscera," was continued with marked success.

L. W. RIGGS

The specificity of ergosterol as parent substance of vitamin D. O. ROSENHEIM AND T. A. WEBSTER. *Nature* **121**, 570(1928).—Evidence from the work of the authors and others indicates that in ergosterol "not only a typical ring structure, but also a sp. position of the 3 unsatd. bonds, is essential for photochem. conversion into vitamin D."

L. W. RIGGS

Vitamin B. CHAS. H. HUNT. *Science* **67**, 556(1928).—The vitamin originally known as "vitamin B" is made up of at least 2 other vitamins which have been sepd from yeast. The yeast residue still contains a third substance which meets all of the definitions of a vitamin. It activates the other 2 vitamins of the vitamin B complex and causes a greater growth than the 2 alone.

L. W. RIGGS

The content of vitamins A and C in water cress. KATHERINE H. COWARD AND P. EGLETON. Univ. of London and Pharm. Soc. of Great Britain. *Lancet* **1928**, **1**, 97-8.—Water cress is a remarkably rich source of vitamin A, 0.1 g. of the green leaf being necessary to promote normal growth in a rat which has become steady in wt. on a diet lacking this factor only. It contains also small quantities of vitamin D and its growth-promoting properties are even stronger in the spring and summer than in the winter. It is a very rich source of vitamin C, 1 g. daily being enough to protect guinea pigs completely for a period of 70 days.

F. B. SEIBERT

FREUDENTHAL, POUL: **Experimental Rickets.** Investigations on the growth-promoting, fat-soluble vitamin, specially elucidated by its relation to experimental rickets. Copenhagen: Levin & Munksgaard. 236 pp. \$10.

F—PHYSIOLOGY

E. K. MARSHALL, JR.

Ammonia of human blood. E. ADLER AND K. SCHWERIN. *Klin. Wochschr.* **6**, 1188-9(1927).—The NH_3 content (actual) of human blood 5-6 min. after withdrawal is 0.02 mg. per 100 cc., while that (virtual) of sterile blood kept at 37° for 24 hrs. is 2 mg. Violent muscular exercise has no effect on the values, but individuals with marked cyanosis

or moribund give high actual values (0.091 mg.). Blood-NH₃ values are independent of the variations in urinary NH₃ elimination. Insulin does not influence the blood-NH₃ value; in four of five cases of carcinoma low virtual and fairly high actual values were obtained. B. C. A.

Pancreas as a source of the fibrin enzyme in blood. V. N. BOLDUIREV AND A. V. BOLDUIREV. *XII Int. Cong. Physiol.* 1926, 22-3.—Total or partial extirpation of the pancreas increases the coagulation time. Later the blood regains its power of coagulation. B. C. A.

Buffering power of urine. S. P. SUNER. *XII Int. Cong. Physiol.* 1926, 135.—The buffering power of urine, which is much greater than that of blood, is a function almost exclusively of the phosphate content. The buffering curve, a straight line, is const. for an individual, but varies among individuals. B. C. A.

Determination of the alkali reserve of the blood. S. P. SUNER. *XII Int. Cong. Physiol.* 1926, 135-6.—The blood (10 cc.) is centrifuged for 10 min. with K oxalate (20 mg.), and 4 cc. of plasma mixed with 16 cc. of distd. water. The p_H is detd. electrometrically before and after the addn. of 0.1-cc. portions of 0.1 N HCl. B. C. A.

Relation between colloids, surface tension, and p_H of urine. S. P. SUNER. *XII Int. Cong. Physiol.* 1926, 135.—On acidification of normal urine, the fall in surface tension runs parallel with that of p_H ; with urine from which colloids have been removed with animal charcoal, the surface tension is unchanged by progressive acidification. B. C. A.

Relation of protein to mineral metabolism. S. LAUTER. *Verh. deut. Ges. inn. Med.* 1926, 330-1.—With a diet rich in carbohydrate and fat and poor in mineral matter, there was an increase in alveolar CO₂ tension and blood-alkali reserve, without change in N excretion, and a decrease in Cl, Na and K. Administration of HCl (oral) and Na dihydrogen phosphate (intravenous) reduces the alveolar CO₂ tension, the blood-alkali reserve, and the p_H of the blood, but there is a marked increase in the NH₃ and N elimination. B. C. A.

Elimination of yellow vegetable coloring matters in human milk. H. PAFFRATH AND A. CONSTEN. *Z. Kinderheilk.* 42, 51-9(1926).—Carotin and xanthophyll were separately detd. in human milk by a colorimetric method. The use of vegetables contg. carotin or xanthophyll increases the amt. of those substances, resp., in the milk. Both are present when white vegetables are employed, and must in this case originate from animal foods. B. C. A.

Influence of intramuscular injection of proteins on glycogen titer. B. RAPINESI. *Boll. soc. ital. biol. sper.* 2, 927-30(1927).—Parenteral injection of blood serum (horse) in dogs caused a marked lowering of free sugar in 4 dogs, although the lowering was not enough to be considered a hypoglycemia, and caused a slight raising of sugar content in two others. Fat-free milk lowered the sugar in 2 subjects only. Casein causes only a slight change either way. Removal of the pancreas before injection of the proteins causes hypoglycemia in 7 cases out of 9. A. W. CONTIERI

The spleen and carbohydrate metabolism. III. The permeability to grape sugar of the erythrocytes. A. NOMA. *Med. Univ. Okayama. Okayama Igakkai Zasshi* 1925, 1125-38; *Chem. Zentr.* 1927, I, 1181; cf. C. A. 22, 2969.—In normal rabbits, glucose is present only in the blood plasma. Even after glucose injections, almost no glucose appears in the erythrocytes. The permeability to sugar of the erythrocytes is not changed either by injections of "Elektrokollargol" or by removal of the spleen. C. C. DAVIS

The fate of *o*-nitrocinnamic acid in the dog's organism. ANAST. A. CHRISTOMANOS. *Z. physiol. Chem.* 176, 74-5(1928).—When *o*-O₂NC₆H₄CH:CHCO₂H is administered orally to dogs only a very small proportion is excreted unchanged in the urine and a still smaller proportion in the form of *o*-nitrohippuric acid. There is no evidence of quinoline ring formation. Intravenous injection of the substance results in a transient lowering of blood pressure. No such effect is obtained with cinnamic acid. A. W. D.

The iron, copper and manganese content of blood serum. EMIL ABDERHALDEN AND PAUL MÖLLER. *Z. physiol. Chem.* 176, 95-100(1928).—Analysis of the ash of horse blood serum showed Cu 1.85-2.11, Fe 1.26-2.35 and Mn 1.15 mg. per 1000 cc. The difference between total Fe and hemoglobin Fe in the serum is practically negligible. Only a small proportion of the Cu and Fe can be removed from the serum by dialysis, and it is doubtful if these metals are present in ionic form. Probably Cu as well as Fe occurs in org. combination. A. W. DOX

The formation of organic bases in the development of the egg. YASUO NAKAMURA. *Z. physiol. Chem.* 177, 34-41(1928).—Free choline occurs in the hen egg only in the yolk. The amt. is very small—0.64 mg. per egg. During incubation the free choline

gradually decreases and reaches a min. in 9 days. Further incubation then results in an increased content in the yolk and in the embryo, the total amt. reaching a value of 2.27 mg. In contrast to the free choline the combined choline is present in the yolk in much greater amt. The max. of 94.34 mg. of total choline is reached in 9 days' incubation, then a decrease occurs and the value drops to 29.54 mg. in 19 days. The increase in free choline during incubation is undoubtedly due to sapon. of the lecithin fraction. Free choline is not, however, the main product of lecithin decompn. since only 2.27 mg. appears during the loss of 65 mg. of combined choline. Whether the choline undergoes further conversion into creatinine is not known. A. W. DOX

The acid swelling of the liver in vitro and the participation of the liver cells in this process. M. A. MAGATH. *Z. ges. expthl. Med.* 52, 41-56(1926).—Micrometric studies of the sectioned surfaces of the liver show that the cells and their nuclei take part in the swelling. On the basis of finding two min. in the swelling curves M. suggests that the swelling in the region of p_{H} 6 is a vital swelling while that occurring around a p_{H} of 4 is a postmortem swelling. F. L. DUNN

Acid swelling of the epithelium of sections of the ureters. N. W. LAZARE. *Z. ges. expthl. Med.* 52, 57-73(1926).—Fresh sections showed a well-marked swelling in lactic acid solns. of p_{H} of 2.6. This was less marked in formalin-fixed specimens. Bibliography. F. L. DUNN

The activity of testicular extracts upon isolated organs. A. A. LIKHATSCHEFF AND M. P. NIKOLAEFF. *Z. ges. expthl. Med.* 52, 418-46(1926).—Perfusion of isolated organs with testicular exts. showed an increase in (1) the output of the heart, (2) the flow through the coronary circulation, and (3) the secretion of urine. Bibliography. F. L. DUNN

The composition of lipoids extracted from the kidney and their role in the secretion of certain dyes. H. S. LARPE. *Z. ges. expthl. Med.* 52, 469-75(1926).—Lipoid analyses of the kidneys of cats were made and compared with the rate of excretion of the dyes, trypan blue, methylene blue and neutral red. Trypan blue appeared in the urine in about 2 min., methylene blue in 16 and neutral red in 22 min. The appearance time is in inverse relation to the soly. of the dyes in lipoids. F. L. DUNN

Studies on local changes in blood composition. I. Alimentary irritation, electrolyte and water distribution. E. WOLLHEIM. *Z. ges. expthl. Med.* 52, 508-23(1926).—In normal dogs following the ingestion of 100-200 cc. of milk the blood peripheral to the liver shows an increase in erythrocytes and protein. At the same time the portal circulation shows an increase in K. Following section of the vagi the protein and erythrocyte contents of the blood of the hepatic vein and of the blood peripheral to the liver show a decrease while the portal vein shows a relative increase in Ca. Injection of K and Ca into the portal vein increases and decreases the concn. of the blood, resp., in the hepatic vein. F. L. DUNN

The physiology of the bile. V. The toxicity of bile acids. E. GILBERT. *Z. ges. expthl. Med.* 52, 779-90(1926); cf. *C. A.* 20, 2013.—The toxicity of the sodium salts of bile acids in rabbits was as follows: glycocholate, 0.09 g.; taurocholate, 0.11 g.; cholate, 0.05 g.; desoxycholate, 0.015 g.; apocholate, 0.009 g.; dehydrocholate 1.1 g. per kg. F. L. DUNN

The reaction of the organism to poisons and functional tests for endocrine secretions. A. STERNBERG. *Z. ges. expthl. Med.* 57, 346-52(1927).—A discussion. Bibliography. Cf. following abstracts. F. L. DUNN

The thyroid and atropine. M. W. IKONEN AND S. M. KUSNETZOWA. *Z. ges. expthl. Med.* 57, 353-60(1927); cf. preceding abstract.—Four parts of serum, 1 part of an atropine soln. and one drop of benzene were mixed and placed in an incubator at 37° for 24 hrs. Two drops of the mixt. were then placed in one eye of a cat and the pupillary dilatation and paralysis observed. The serum of normal cats will neutralize up to a 1.50 soln. of atropine. Following thyroidectomy this power is lost but returns when thyroid gland is transplanted. Similar results are obtained in patients with thyroid disorder and the method is suggested as a test for thyroid secretion. F. L. D.

The thyroid gland and physostigmine. S. ENDER AND M. PLITMAN. *Z. ges. expthl. Med.* 57, 361-5(1927); cf. preceding abstracts.—Physostigmine has the reverse action to atropine. Blood serum contains substances which have the property of inhibiting the action of atropine or physostigmine. Chem. studies showed that the property was in the albumin fraction. F. L. DUNN

The heart and internal secretions. LADISLAUS TAKÁCS. *Z. ges. expthl. Med.* 57, 514, 520(1927).—Using frog hearts and immersing them in Ringer soln. contg. various exts. T. showed that exts. of thyroid, hypophysis, spleen, adrenal, breast, testis, ovary,

sinus hormone, parathyroid, secretin, thymus, and corpus luteum, increased the contractility and response of the heart. F. L. DUNN

Experimental studies on bile secretions. J. SCHAFFLER. *Z. ges. expl. Med.* 57, 672-97(1927).—The effects of meat, rice, bacon, paprika, pepper, onions, cincho-phen menthol, dehydrocholic acid, "felagol" and "cholaktol" were detd. in bile fistula dogs. A definite cholagog action in the therapeutic dosages was found only for cincho-phen and dehydrocholic acid. Bibliography. F. L. DUNN

The inorganic phosphorus in human whole blood and corpuscles. HEINRICH SEIDEL. *Z. ges. expl. Med.* 57, 698-708(1927).—Embsden's method (*C. A.* 16, 267) was modified into a micromethod and compared with a nephelometric method. Normal inorg. concns. in whole blood were 3.2 to 4.5 mg. % and in the corpuscles 2.9 to 5.0 mg. Adrenaline gave an increase in healthy normals of 0.6 to 1.2 mg. %, while insulin had no effect. Insulin in diabetics produced a decrease. S. corroborates Lawasceck's values on the lowering of the inorg. P when the blood is treated with bicarbonate (*C. A.* 19, 100). F. L. DUNN

Studies on the refraction difference. I. F. HOGLER AND K. UEBERRACK. *Z. ges. expl. Med.* 58, 22-39(1927).—Refractometric detns. were made on plasma and serum, called as albumin, and the difference was recorded as the refraction difference. Long-continued hunger, thirst and loss of blood decrease the refraction difference (*R. D.*) Hard work increases the *R. D.* II. **Influence of swelling.** *Ibid* 40-50.—Under the action of swelling the *R. D.* decreases and even becomes negative. The fibrin content of the plasma remains unchanged or may increase a little. III. **Influence of electrolytes and nonelectrolytes.** *Ibid* 51-75.—In normal people the diuresis following the ingestion of water, K, Ca and Cl salts resulted in a reduction of the *R. D.* The fibrinogen content of the blood was not markedly changed. In pathol. cases the *R. D.* increased with the edema, and varied inversely with the diuresis. IV. *Ibid* 76-80.—Sweating decreases the *R. D.* F. L. DUNN

The physiological chemistry of the aging of tissues. II. **Studies on beef lens.** M. BURGER AND G. SCHLONKA. *Z. ges. expl. Med.* 58, 710-24(1928).—The water content of healthy beef lens changes from 68.5% in the first year to 63.4% in the fourth five-year period, the N content rising from 5.04 to 5.89%. N detns. on the dried lens were 16% in the first year, 16.5% in the second five-year period, and 16.1% in the fourth five year period, the cholesterol content being 40 mg. % at birth and 222 mg. in the 15th year. The ash constituents did not change appreciably with age. F. L. D.

The activity of the mammary gland as determined by analysis of mammary blood before and after milking. E. A. COCKEFAIR. *J. Dairy Sci.* 11, 230-9(1928).—Samples of blood from the mammary veins of lactating cows were taken just before milking, and samples of jugular blood immediately after the mammary samples. After milking another mammary sample was removed from the same vein as before. Six cows were so tested, with 10 to 20 tests per cow. Mammary blood before milking is higher in both inorg. and lipid P than systemic blood, and in a after milking mammary blood both forms of P, in approx. the same degree, are lower than in systemic blood. It is concluded that just before milking synthesis of milk is practically nil, which allows the blood to retain its load of lipoids. At the same time inorg. P liberated during the hours of active secretion is being absorbed by the blood. Just after milking lipoids are being used for milk fat synthesis, and inorg. P liberated by the process is not at once reabsorbed by the blood because the main osmotic current is toward the alveolar cells. Four to 6 hrs. later inorg. P in mammary blood increases because the osmotic interchange is sufficiently equalized to allow its return. Milk secretion is most active just after milking and proceeds in diminishing rate as the pressure and presence of accumulating synthesized milk interferes with cellular activity. W. C. EBAUGH

Respiratory metabolism in infancy and childhood. V. **Effect of moderate exercise on the respiratory quotient.** J. R. WILSON, H. RVKIN, S. Z. LEVINE AND F. BERLINER. *Am. J. Diseases Children* 33, 618-29(1927); *Physiol. Abstracts* 12, 567.—The respiratory quotient during moderate exercise was similar to that during rest in normal children (2 cases), in a girl with cyclic vomiting, and in a boy with mild diabetes, showing that the proportions of fat and carbohydrate burnt did not vary appreciably; with vigorous exercise the boy with diabetes showed some increased metabolism of fat. The respiratory quotient of the extra metabolism due to exercise was always less than unity—i. e., less than that obtained by combustion of pure carbohydrate. H. G.

Lipin metabolism and generative glands. R. JAFFÉ. *Arch. Frauenk. Konst.* 12, 368-76(1926).—A survey. H. G.

Respiration and glucolysis of the skin and the influence of hormones. E. KROCK. *Dermatol. Woch.* 83, 1468-71(1926).

Action of hormones on cell oxidations. E. SEGHI. *Riv. patol. sper.* 2, 280-7 (1927); *Physiol. Abstracts* 12, 575.—A small increase in oxidative activity of embryonic tissue of fowls and Rous sarcoma is produced by hypophysin. No change is produced by thyroïdin, paraganglin, adrenaline, nor is it produced in adult muscular tissue.

H. G.

Comparative studies of the metabolism of amino acids. I. Changes in the non-protein nitrogenous constituents of the blood following administration of amino acids. M. W. JOHNSTON AND H. B. LEWIS. Univ. of Mich. *J. Biol. Chem.* 78, 67-82(1928).—After the administration of an amino acid to rabbits, the rate of its metabolism is detd. by the rate of absorption and of deamination in the organism. Alanine and glycine were absorbed more rapidly than glutamic acid but the deamination of glycine is slower than the others. An increase in the "undetermined" N of the blood occurs regularly after the administration of glycine and occasionally after *dl*-alanine, possibly as a result of peptide synthesis.

ARTHUR GROLLMAN

The distribution of sugar in normal human blood. M. SOMOGYI. Jewish Hospital, St. Louis. *J. Biol. Chem.* 78, 117-27(1928).—The ratios of the sugar present in corpuscles and in plasma of human blood differ considerably when true and apparent sugar values are used. When the true values are used a const. ratio is obtained. The previously described method (*C. A.* 21, 752) for detg. the true sugar in blood is modified.

ARTHUR GROLLMAN

Studies in calcium metabolism. II. The calcium content of corpuscles, plasma and serum. C. P. STEWART AND G. H. PERCIVAL. Univ. of Edinburgh. *Biochem. J.* 22, 548-58(1928); cf. *C. A.* 21, 2923.—The Ca content of true plasma is 10-20% greater than that of the corresponding serum. The addn. of Na citrate to true plasma in concn. of 1% causes some of the Ca to be pptd. The Ca content of citrated centrifuged plasma is roughly equal to that of the corresponding serum. The corpuscles contain but traces of Ca. In plasma the concn. of ionic and of diffusible Ca appears to be equal to that in serum. The authors suggest that during the coagulation of blood some of the non-diffusible Ca is pptd. **III.** *Ibid* 22, 559-70(1928).—From expts. on the effect of Na citrate, NaF, NaCl and Na₂C₂O₄ on the coagulation time of ox blood and on the concn. of Ca, diffusible Ca and ionic Ca of the corresponding serum, the authors conclude that Vine's view (*C. A.* 15, 3313), that some complex, undissociated Ca compd. is necessary for coagulation, is correct. Ca ions are not necessary. BENJAMIN HARROW

Metabolism in infancy. PHILIP S. POTTER. *Arch. Pediatrics* 45, 410-23(1928).—Review on the basal metabolism and energy requirements of infants, with bibliography.

JOSEPH S. HEPBURN

Composition of milk from a lactating heifer calf. ANON. *J. Dept. Agr. Victoria* 26, 137(1928).—The compn. of milk from a 3-months old heifer calf, lactating since birth, was H₂O 87.57, fat 3.0, protein 3.65, ash 0.74, and sugar 5.04%. K. D. JACOB

Sugar in milk. J. F. TOCHER. *Scottish J. Agr.* 10, 408-15(1927).—The av. sugar content varied from 4.62% in milk from Freisian cows to 4.85% in that from Jersey cows. The sugar content of milk from 676 individual cows varied from 2.7 to 5.5%, 80% giving milk contg. 4 to 5% sugar. In general the % of sugar varied inversely as the albumin and the mineral content of the milk, and was directly proportional to the amt. of milk given at one time. The sugar content was highest at the beginning of lactation and decreased gradually and uniformly during 44 weeks. K. D. JACOB

Effect on basal metabolism of ligating lower extremities. ANNE TOPFER AND HANNAH MULIER. *Arch. Internal Med.* 41, 655-62(1928).—Expts. on 2 human subjects confirm Helmreich's statement that basal metabolism depends on the mass (amt. of active protoplasmic tissue) rather than on the body surface. MARY JACOBSEN

Muscle glycogen as a source of blood sugar. S. SOSKIN. Univ. of Toronto. *Am. J. Physiol.* 81, 383-91(1927).—The administration of adrenaline to dogs from which the intestines, spleen, pancreas and liver had been removed did not result in raising the blood-sugar level. Conclusion: The liver is the sole source of supply of blood sugar; glycogen, once deposited in the muscle, cannot be returned as sugar to the blood.

J. F. LYMAN

Medullary-adrenal secretion and carbohydrate metabolism. S. W. BRITTON AND E. M. K. GEILING. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 81, 467(1927).—The effect of insulin on blood sugar was 10 times as pronounced in animals in which the adrenal medulla had been inactivated as in normals. The depression of the sympathetic nervous system by ergotamine further, but only slightly, accentuated this hypersensitivity. Conclusion: A highly potent secretion from the adrenal medulla, tending toward depletion of the glycogen stores of the body while supplying sugar to the blood stream, takes place during insulin hypoglycemia.

J. F. LYMAN

The physiology of gastric secretion. I. Gastric phase. JAMES I. FARRELL. Proc. Am. Physiol. Soc., *Am. J. Physiol.* **81**, 475(1927).—H₂O, 0.1 N HCl and NaHCO₃ produced no change in gastric secretion after their introduction into a gastric pouch. Gastric juice of a high acidity did not increase the secretion; on the contrary the acidity of the juice introduced was lowered. Olive oil inhibited secretion. Alc., "bitters," *e. g.*, tincture of gentian, stimulated the flow of juice. An aq. soln. of gentian had no action; hence probably it is the alc. rather than the gentian which stimulates the gastric juice. Raw meat juice stimulates the flow of juice, but meat juice boiled 30 min. lost its stimulating power. Meat exts. and meat digested with pepsin were stimulating. Lactic acid, Armour's scale pepsin, NaCl, bread juice and sucrose had no action.

J. F. LYMAN

The bilirubin content of the blood following injections of chlorophyll. JESSE L. BOLLMAN, CHARLES SHEARD AND FRANK C. MANN. Mayo Foundation *Am. J. Physiol.* **82**, 239-40(1927).—There was no alteration in the rate of bilirubin. formation in dogs following the intravenous injection of chlorophyll.

J. F. LYMAN

Effects of thermal and chemical applications to the exposed medulla of the dog. E. S. GURDJIAN. Univ. of Mich. *Am. J. Physiol.* **82**, 261-8(1927).—When the exposed floor of the fourth ventricle (respiratory center) was heated to 75° respiration was arrested, normal respiration ensued again as soon as the temp. fell back to normal. Strong salt solns increased the respiratory rhythm. CO₂ and lactic acids poured over the nervous center had little effect, probably on account of their failure to penetrate the tissues fast enough. Crystals of NaCN placed on the center caused a marked rise in blood pressure.

J. F. LYMAN

Bone marrow reactions. IV. The influence of liver and meat diets on the bone marrow and the regeneration of red blood cells and hemoglobin. GULLI LINDH MULLER. Boston City Hosp. *Am. J. Physiol.* **82**, 269-78(1927).—Pigeons were starved until the bone marrow in the radius and ulna was reduced to comparative aplasia and the blood gave evidence of anemia; then 3 diets were fed. (1) grain (control), (2) boiled beef liver, (3) boiled beef muscle. The grain and meat diets permitted complete regeneration of the red blood cells and hemoglobin in less than 3 weeks. The liver diet was very effective for about 12 days. A decline then set in; appetite failed, weight declined and the red blood cells and hemoglobin fell. The suggestion is made that liver contains inhibitory factors which suppress blood formation in the megaloblastic stage.

J. F. L.

The efficiency of the heart, and the significance of rapid and slow pulse rates. YANDELL HENDERSON, HOWARD W. HAGGARD AND FRANK S. DOLLEY. Yale. *Am. J. Physiol.* **82**, 512-24(1927).—Results for circulation rate, O₂ consumption, pulse and respiration for 50 men including athletes and non-athletes are given. In athletes the pulse rate tends to be much slower and the stroke vol. distinctly larger both during rest and exercise than in non-athletes. Since there is ample time in athletes for the ventricles to relax and fill the stroke vol. during exertion may be increased considerably, 50% or more, over that at rest.

J. F. LYMAN

The alleged interrelationship of the pancreas and the thyroid. LEONARD BENJAMIN SHPNER. Univ. of Chicago. *Am. J. Physiol.* **83**, 134-40(1927).—The thyroid seems to influence carbohydrate metabolism only indirectly through its effect on the basal metabolic rate.

J. F. LYMAN

The gas exchange of isolated muscles during stimulation and recovery. WALLACE O. FENN. Rochester Univ. *Am. J. Physiol.* **83**, 309-22(1927).—The extra O₂ consumed by a small frog muscle in recovering from a 5-20-sec. tetanus was measured. The excess O₂ consumption was nearly but not quite doubled when the duration of tetanus was doubled. The lactic acid formation as measured by Embden would require about 5.7 times as much O₂ for its combustion as the muscles were observed to consume. The respiratory quotient of resting muscles was 0.92; that of the excess O₂ consumption was 0.93. After stimulation, O₂ diffused into a muscle faster than CO₂ diffused out; this was due to the greater soly. of CO₂ in the muscle fluids.

J. F. LYMAN

Relation of the hydrogen-ion concentration of the blood to the irritability of the vasoconstrictor mechanism. G. E. BURGET AND GEORGE CRISLER. Univ. of Chicago. *Am. J. Physiol.* **83**, 373-8(1927).—The greater irritability of the vascular system of the pithed cat to adrenaline in a more alk. medium (within the range p_H 6.85 to 8.0) is due to a change in irritability of the structure acted upon by adrenaline, rather than to any effects produced by a change in the rate of oxidation of adrenaline in the blood.

J. F. LYMAN

Gaseous metabolism of the dog's kidney. J. M. HAYMAN, JR., AND C. F. SCHMIDT. Univ. of Penn. *Am. J. Physiol.* **83**, 502-12(1928).—In 9 dogs the O₂ consumption of the kidney varied from 0.009 to 0.113 cc. per g. per min.; the higher figures usually

panied the greater blood flow and more profuse diuresis. The injection of urea, caffeine, Na_2SO_4 or some drugs was not followed by any characteristic effect on O_2 metabolism.

J. F. LYMAN

An attempt to strike a balance of carbohydrate metabolism at the time of rapid changes in blood sugar and liver glycogen. J. M. D. OLMSTED AND H. S. COULTHARD. Univ. of Toronto. *Am. J. Physiol.* **83**, 513-27(1928).—Glycogen, glucose and lactic acid of the liver, glucose in the blood and glucose used in metabolism were detd. in dogs. If the muscle glycogen is not involved in the carbohydrate changes noted, it seems likely that carbohydrate can exist in the organism in some form other than glycogen or glucose, which, therefore, escapes detection when the usual quant. methods are used for the detn. of these carbohydrates.

J. F. LYMAN

Bile salts and secretin as cholagoges. J. MELLANBY. St. Thomas's Hospital, London. *J. Physiol.* **64**, 331-40(1928).—Bile, placed in the duodenum, stimulated the secretion of both pancreatic juice and bile, placed in the ileum it stimulated the liver and not the pancreas. Injected into the blood, bile salts stimulated bile flow and had no effect on pancreatic secretion. Purified secretin, injected intravenously, stimulated both pancreatic and liver secretion. Conclusion: (1) Bile salts act as direct cholagoges. (2) The action of secretin as a cholagog is secondary to its action on the pancreas.

J. F. LYMAN

The diminution of the titratable alkalinity of the blood in rarified air. G. FERRALORO. *Arch. sci. biol.* **8**, 99-111(1926).—The diminution of titratable alk., of the blood caused by low barometric pressure (400-410 mm Hg) was detd. 5 min. after exposure to rarified air, the alk. diminished, the diminution increased with the time. Shortly after removal from rarified air, the alk. returned to normal. No hyperglucemia was noted. If O_2 , or O_2 and CO_2 , or air with a low O_2 tension and a high per cent CO_2 , was inspired the alk. remained const. Apnea is therefore caused by the diminution of the alk. The phenomenon is assumed to take place as follows: Anoxemia caused by low O_2 tension of the rarified air brings about hyperpnea, hyperpnea causes apnea which in turn sets free the bases. These are eliminated by the kidneys through the urine. Thus, the titratable alk. of the blood is diminished.

PETER MASUCCI

Experiments on the dehydrogenation processes of tissues in vitro. G. PENNETTI. *Arch. sci. biol.* **8**, 452-63(1926).—From expts. made with Lapschuetz's method on the dehydrogenation of tissues *in vitro* P. obtained the following results: Veronal and morphine-HCl do not exert any action on the dehydrogenation processes of hepatic, renal, or nervous tissues of recently killed dogs. Br. in the form of the Na and K salts inhibits respiration in a concn. of 1:1000. Digitalin, sparteine SO_4 , and heliochrom are inactive. Quinine in a diln. of 1:2500, quinidine in 1:200 inhibit the oxidation of the cells *in vitro*; phenocoll is inert.

PETER MASUCCI

The influence of nuclei of the brain on the equilibrium of electrolytes in the blood. LUIGI CONDORELLI. *Boll. soc. ital. biol. sper.* **2**, 252-4(1927).—The various brain centers were operated on in rabbits in order to study the changes produced in the equil. of electrolytes in the blood; the results showed very definitely that in the optic thalamus there are important regulatory centers for Ca, K and P. The results for Cl and Na were not as clean-cut.

PETER MASUCCI

The presence of phosphagen in the heart. G. MARTINO. *Boll. soc. ital. biol. sper.* **2**, 1019-22(1927).—Phosphagen is present in the ventricular muscles of the heart. The atrial muscles do not contain any. There is no important difference in the amt. found in the ventricular muscles of the rabbit, dog or pigeon.

P. MASUCCI

Muscle phosphagen and cadaverous rigidity. G. FALCO. *Boll. soc. ital. biol. sper.* **3**, 222-5(1928).—Phosphagen was found in relatively the same amts. in the muscles of animal and human cadavers in various conditions of rigidity. There was an increase in the amt. of inorg. phosphoric acid. The behavior of phosphagen in cadaverous rigidity is different from that of other muscle contractions so far studied.

PETER MASUCCI

Probable influence of pancreatic juice in the regulation of gastric acidity. ROBERT ELMAN. Washington Univ., St. Louis. *Arch. Surg.* **16**, 1256-65(1928).—During drainage of the total pancreatic juice, the gastric contents contain a far higher total and combined acid than normal. Acid solns. introduced into the stomach of animals during such drainage provoke an intense increase in the flow of pancreatic juice to the outside, but cannot be neutralized as in the normal animal. Such drainage is also accompanied by regurgitation of intestinal contents into the stomach. Analysis of this leads to the hypothesis that reduction of gastric acidity is normal and probably an essential phenomenon, caused by the reflux of alk. pancreatic juice into the stomach.

Bile being actually an acid rather than an alkali cannot take part in this neutralization.

JOHN T. MYERS

The two products of thyroid activity. GEO. S. WILLIAMSON, INNES H. PEARSE AND H. M. CUNNINGTON. St. Bartholomew's Hosp., London. *J. Path. Bact.* **31**, 255-64(1928); cf. *C. A.* **21**, 3226.—The morphology of secretory tissue permits its selection from the normal thyroid gland in comparative purity, and the same is true of colloid tissue. The capacity of the alveoli in each phase was about the same. Thyroid tissue in the phase of secretion is biologically inactive, but in the colloid phase is active even if the I content is as low as 0.008%. Secreting tissue in 94% of sample yields no I. Colloid tissue contains I in 100% of samples. The alveolar contents during the secreting phase contain no I, but it is always present during the colloid phase. The thyroid gland produces 2 substances, secretion proper and iodo-colloid; hence it has a dual function both in health and disease.

JOHN T. MYERS

Application of Meinicke's opacity reaction to the examination of cerebrospinal fluids. S. MUTERMILCH AND (MLLE) E. SALAMON. *Compt. rend. soc. biol.* **98**, 822-5 (1928); cf. Meinicke, *C. A.* **18**, 1855.—This procedure has similar advantages in the examn of cerebrospinal fluids to those already noted in the examn. of serums. This reaction has a certain independence of other reactions such as Bordet-Wassermann, colloidal benzoïn, elixir paregoric, etc.

L. W. RIGGS

Cadmiphile cells of the lungs. J. LECLOUX. *Compt. rend. soc. biol.* **98**, 943-5 (1928).—Guinea pigs were fed rations which were normal, lacking or rich in S. Some of the animals were given intraperitoneal injections of colloidal S, or a 3 to 7 months use of a sulfur drinking water. Sections of lung tissue in formol with 3% CdCl₂ were studied histologically. The diet did not influence the content of glutathione or cysteine in the lung tissue. Cadmiophile cells varied in different animals but had no relation to the glutathione content. The injection of colloidal S did not affect the glutathione content of lung tissue or the no. of cadmiophile cells. The epithelial cells of the intoxicated lung show no increase in cadmiophule cells.

L. W. RIGGS

Antagonism of the thymus and thyroid in their influence on body weight. J. KŘÍŽENĚCKÝ. *Compt. rend. soc. biol.* **98**, 1031-3(1928).—Feeding tests with pigeons proved that the diminution of wt. by hyperthyroidization was largely arrested by simultaneous hyperthymusization. These results confirm those of Sklower, cf. *Z. vergleich. Physiol.* **6**, 150, with white mice.

L. W. RIGGS

Absorption of fats by the frog skin. O. V. HYKES. *Compt. rend. soc. biol.* **98**, 1038(1928).—Not only sol. substances but fats in emulsion may be absorbed through the skin of the frog or tadpole.

L. W. RIGGS

Relation between the spleen and other hematopoietic organs. L. DRASTICH. *Compt. rend. soc. biol.* **98**, 1039(1928).—Fifteen white mice were kept in a rarified atm. at 300 mm. Hg whereupon their red corpuscle count increased from about 8.7 to 13.8 million. Five animals were kept as controls, 5 were splenectomized when their erythrocyte count fell to 11.0 million and 5 were splenectomized and given injections of ground spleen when the erythrocyte count fell to 12.3 million. The hemoglobin content passed through changes parallel to those of the erythrocytes. The vol. of the erythrocytes per 100 cc. of blood in the normal mice was 41.75 cc., in the 5 controls 65.1, in the 5 splenectomized 62.02 and in the 5 splenectomized and injected with ground spleen 67.37.

L. W. RIGGS

Lowering of the hemoglobin concentration in the erythrocytes of animals under the influence of rarified air. L. DRASTICH. *Compt. rend. soc. biol.* **98**, 1040-1(1928).—The slight decrease in hemoglobin per 100 cc. of erythrocytes in the blood of animals subjected to an atm. of 400 mm. of Hg is probably because the newly formed erythrocytes have not produced their normal quantity of hemoglobin. Possibly the older erythrocytes may have lost a part of their hemoglobin, or the vol. of the erythrocytes has increased while the hemoglobin per cell has not increased.

L. W. RIGGS

Study of the portal blood collected by the intermediary of a para-umbilical vein. A. DAMBOVICEANU, SERBAN BRATIANU AND N. VISINEANU. *Compt. rend. soc. biol.* **98**, 1075-7(1928).—The portal blood as compared with the peripheral blood has a higher pH, urea and uric acid content; an equal or nearly equal content of glucose, heterolysins, bilirubin and lipase, and a nearly equal globular resistance, but a lower content of erythrocytes, hemoglobin, leucocytes, cholesterol, catalase and amylase.

L. W. R.

Glycogen reserves and their physiologic role. H. BIERRY. *Compt. rend. soc. biol.* **98**, 1387-9(1928).

L. W. RIGGS

Technic of a study of adrenaline in human suprarenal capsules after death. MARCEL PAGET and PAUL LOHÉAC. *Compt. rend. soc. biol.* **98**, 1421-3(1928).—Existence of adrenaline in free and virtual states in the human suprarenals removed after death,

Influence of cadaverization. LANGERON, M. PAGET AND P. LOHÉAC. *Ibid* 1424-6.—No trace of adrenaline was found in human suprarenals removed 30 hrs. after death. The existence of virtual adrenaline appears to be proved. A more complete paper on this subject is to be issued. L. W. RIGGS

Influence of the time interval in taking samples of urine on the constant of Hasselbalch. MICHEL, POLONOVSKI AND PAUL BOULANGER. *Compt. rend. soc. biol.* 98, 1427-8(1928); cf. *C. A.* 22, 2972.—Samples of urine were taken every hr. for 6 hrs. and every 3 hrs. for 15 hrs. and one sample following these after a 9-hr. interval. The p_H and ammonia coeff. were detd. and tabulated. Samples taken at different hrs. were mixed and the same factors were detd. for the mixed samples. The application of the formula of Hasselbalch to the numerical findings is discussed. L. W. RIGGS

Precipitogenic properties of buffalo milk. K. KATRANJIEFF. *Compt. rend. soc. biol.* 98, 1508-10(1928).—It is concluded that casein, and not globulin, plays the principal role in the formation of precipitins of milk. L. W. RIGGS

Influence of pregnancy on the water content of blood, muscular tissue and certain organs. C. I. PARION, M. CAHANE AND V. MARZA. *Compt. rend. soc. biol.* 98, 1625-7(1928).—A study with guinea pigs showed that hydration is greater in pregnant females in the blood, muscles, liver and kidneys. L. W. RIGGS

Iron of mammalian lung and the formation of melanic pigment. F. GRANEL AND L. HÉDON. *Compt. rend. soc. biol.* 99, 22-4(1928).—Histological. L. W. RIGGS

Influence of the Krough method on the rate of respiration. E. SCHILL AND G. BAITZ. *Magyar Orvosi Arch.* 29, 231-5(1928).—Behavior of the respiratory metabolism in long-period experiments. E. SCHILL. *Ibid* 236-8. In prolonged fasting expts. with man the results are partly in agreement and partly differ by as much as 15%. Therefore, the influence of any factor on the respiratory metabolism can be considered only when the resulting difference is more than 15%. L. W. RIGGS

The copper peroxidase reaction of animal blood. KENJI SHOJI. *Tôhoku J. Exptl. Med.* 10, 293-8(1928).—The original Cu method of Sato and Sekiya (cf. *C. A.* 20, 2515) may be applied successfully to animal blood. With rabbit blood it is best to use twice as much H_2O_2 in Solution B as in the original method. Of all the animals tested (cat, guinea pig, rat, mouse, frog, domestic fowl, pigeon, sheep, carp and rabbit) in no species were the myeloid elements of the blood peroxidase-negative. In more than 700 rabbits tested no one was found peroxidase-negative except those successfully "peroxidase punctured." Differentiation of myeloid and lymphatic leucocytes of animal blood in the counting chamber. *Ibid* 299-304.—Certain modifications of the reagents as used for human blood are necessary in the application of the method to animal blood. These modifications are described at length. Rapid differentiation of lymphatic and myeloid leucocytes in the spinal fluid in the counting chamber. *Ibid* 305-6.—Histologic directions are given. L. W. RIGGS

Is the hyperglucemia-provoking capacity of asphyxial blood due to adrenaline? HOROSHI TACHI AND SHIZUKA SAITO. *Tôhoku J. Exptl. Med.* 10, 426-34(1928).—The asphyxiated blood of rabbits from the general circulation is capable, though not invariably, of causing a slight degree of hyperglucemia when intravenously introduced in amts. of 10 to 15 cc. in a rabbit of about 2 kg. wt. This hyperglucemia is in addn. to the increased sugar concn. due to sugar in the introduced blood. Practically no adrenaline was found in defibrinated asphyxial rabbit blood from the general circulation when tested by the rabbit intestine segment method. L. W. RIGGS

The formation of sacrolactic acid in the animal organism. AKISUKE MATSUMOTO. *Acta Schol. Med. Univ. Imp. Kioto* 10, 261-4(1928).—The influence of an addn. of glycerol on the lactic acid formation during autolysis was studied. Fresh, finely chopped testicles of bulls were digested for 4 days at a temp. of 37°, after adding chloroform-water and different amts. of glycerol. Then the lactic acid was detd. polarimetrically; its value was found to be slightly increased. The max. amt. obtained was 0.250%, while the controls without the addn. of glycerol contained 0.117 and 0.134%, resp. G. SCHWOCH

A note on the normal serum calcium content of man. JOSEPH H. ROE AND BERNARD S. KAHN. *J. Lab. Clin. Med.* 13, 762-3(1928).—Ca was detd. in the serums of 50 normal subjects by the method described in *C. A.* 20, 3474. The values vary from 9.0 to 11.6 mg. per 100 cc. of serum, the av. being 10.13 mg. These findings are in accord with the generally accepted normal of 9 to 11 mg. per 100 cc. of serum, as against the findings of Rosen and Krasnow (*C. A.* 22, 2179). ETHEL WICKWARE

GAUTIER, CLAUDE, AND WOLFF, RENÉ. Le métabolisme basal—ses applications en clinique. Paris: G. Doin & Cie, 172 pp.

G—PATHOLOGY

H. GIDEON WELLS

Kidney disease and serum calcium index. FERDINAND LEBERMAN. *Wiener klin. Wochschr.* 41, 695-8(1928).—A serum Ca index below 9.5 mg. % is evidence of kidney insufficiency. However, normal values are sometimes observed in kidney insufficiency and in early phases serum Ca may be above normal. D. B. DILL

The hepatic function in pregnancy examined by means of tetrachlorophenolphthalein. F. D'APRILE. *Arch. farmacol. sper.* 44, 193-224(1928).—A report and discussion of clinical tests, using the Rosenthal technic. The dye appears to have no sp. affinity for hepatic cells, reticulo-endothelial system or other tissues. Retention is most marked when pregnancy is accompanied by icterus. A. W. DOX

The physicochemical properties of the cerebrospinal fluid in tuberculosis meningitis. ENDRE TUDOS AND ALFRED EBEL. *Z. ges. expul. Med.* 57, 715-20(1927).—The elec. cond. of normal cerebrospinal fluid in children is 1.30×10^{-2} mho and in tuberculous meningitis is 1.26×10^{-2} mho as compared with serum which is 1.08×10^{-2} mho. The chloride content is higher than serum but is reduced in tuberculous meningitis. Analogous changes were obtained for the refractive index. F. L. DUNN

Basal metabolism and polarization capacity of the skin in relation to the function of the thyroid. WERNER LURG AND KURT GRASSHEIM. *Klin. Wochschr.* 7, 647-8(1928).—An elevation in the basal metabolic rate is associated with a roughly proportional elevation in the polarization capacity of the skin. MILTON HANKE

The sedimentation rate of erythrocytes. Its relation to fibrin value and cholesterol content and its application in tuberculosis. M. PINNER, K. KNOWLTON AND R. G. KELLY. *Arch. Path. Lab. Med.* 5, 810-27(1928).—The blood of persons in perfect health not infrequently had a sedimentation rate markedly higher than the usually accepted normal values. The fluctuations of the rate in normal persons were much greater than they are usually reported to be. A quant. relation between the fibrin content of the blood and the sedimentation or between cholesterol content and sedimentation rate could not be ascertained in clinical tuberculosis, under normal conditions or during slight phys. disturbances. Although a higher av. rate is found in active tuberculosis than under normal conditions, this increase is far from const. and it is not parallel with the extent and the progressiveness of the lesions. The prognostic value of the sedimentation is minimal, and, with the exception of extremely rare instances, this test is not apt to furnish information beyond that gained by clinical and bacteriologic observations. The clinical value of fibrin detns. in clinical tuberculosis is of the same order. HARRIET F. HOLMES

Electropathology. A review of the pathologic changes produced by electric currents. R. H. JAFFÉ. *Arch. Path. Lab. Med.* 5, 837-70(1928).—A general review. HARRIET F. HOLMES

The modification of scarlatinal toxin by formaldehyde. J. SMITH. *Brit. J. Exptl. Path.* 9, 49-54(1928).—Various expts. on the modification of scarlatinal toxin have shown that many weeks are required to produce the anatoxin unless formalin is present in great excess. Immunization by means of toxin modified by 2 or 1% formalin is impracticable because of the pain produced by the excess of formalin. The discomfort caused by inoculating with the toxoid modified by 0.5% formalin was, however, trifling, and none of the children developed the scarlatinoid syndrome following an injection of any of the toxoids. Although the percentage of individuals rendered immune to the Dick dose of toxin has not been high, the results suggest that further expts. should be carried out. HARRIET F. HOLMES

Pancreatic fat necrosis: a chemical study. FRED A. K. HERBERT. *Brit. J. Exptl. Path.* 9, 57-63(1928).—Histochem. observations confirm the accepted opinion that soap is formed in the necrotic areas in pancreatic fat necrosis. Possibly neutral fat, fatty acid and soaps are all present in cryst. form. There is certainly more than one type of crystal, but histochem. identification is unsatisfactory. By chem. analysis it has been shown that hydrolysis and sapon. of the fat do occur in pancreatic fat necrosis, but the hydrolysis is mainly an acid hydrolysis, and very little soap is formed. There is a marked rise in the Ca content of the omental tissue when the fat necrosis is extensive, but only a minute portion of this Ca exists as soap. H. F. H.

Blood phosphorus in health and disease. III. A. The alleged value of blood phosphorus determinations in suspected malignant disease. B. The phosphorus distribution in anemic, polycythemia and leucemia. F. B. BYROM AND H. D. KAY. *Brit. J. Exptl. Path.* 9, 72-81(1928); cf. C. A. 22, 1622.—In malignant disease unaccompanied by anemia there is no significant change, as compared with non-anemic non-

cancerous controls in the amt. of any of the following kinds of P compds. in the blood: free phosphate, phosphoric esters hydrolyzed by phosphatases, phosphoric esters not hydrolyzed by phosphatases, lipin P, total P. In malignant disease accompanied by anemia the changes which occur in the above blood constituents are entirely explicable on the basis of the anemia, and are in no way specific for cancer. The detn. of the "phosphorus quotient" as described by Gröbly (*C. A.* 16, 4270) is of no diagnostic value in this disease. In severe obstructive jaundice, such as that accompanying carcinoma of the pancreas, the lipin P of the blood is markedly increased. In polycythemia and simple secondary anemia, as in the anemia of carcinoma, the changes from the normal in the blood P distribution are the result merely of a change in the relative proportion of the red cells to plasma. This is not the case in the anemia of advanced chronic nephritis or in pernicious anemia, in both these diseases the qual. and quant. compn. of the cell with regard to P compds. appear to be changed. Leucocytes are relatively rich in P compds., a given vol. of leucocytes contg. 2 to 3 times the quantity of P as the same vol. of red cells. In leucemia, therefore, P detns. on the whole blood vary with the severity of the anemia and the leucocytosis in an irregular manner. H. F. H.

The structure of the *V. cholerae*, with reference to its immunizing properties. R. W. FAIRBROTHER. *Brit. J. Exptl. Path.* 9, 89-96(1928) --The substance of *V. cholerae*, which, on inoculation, gives rise to protection in animals, is intimately connected with the body protoplasm; it is also heat-stable (100° 1 hour). It is present only in small quantity in the supernatant fluid of a 24-hour bouillon culture after centrifugalization. HARRIET F. HOLMES

Differentiation of achylia by fractional removal of the stomach contents after the injection of histamine; and the determination of pepsin in the urine. HANS J. TESCHEN DORF. *Deut. Arch. klin. Med.* 155, 43-51(1927) --A rapid increase in the acidity of gastric juice was observed after the injection of 0.5 mg histamine. Before the ingestion of food no pepsin was found, after stimulation with alc. only traces; but after the injection of histamine pepsin was found in normal amts. In the urine in some cases normal amts of pepsin were found after the injection, but in other cases subnormal amts. P. Y. JACKSON

Disturbance of carbohydrate metabolism during diphtheria. ARTHUR ELKELES AND FRANZ HEIMANN. *Deut. Arch. klin. Med.* 155, 263 9(1927) --In moderate and severe cases of diphtheria cases were observed with normal, excessive, and subnormal concn. of glucose in the blood. The administration of 10-20 g glucose was followed, even after 2 hrs., by an increased concn. of blood glucose, but no glucosuria was observed. P. Y. JACKSON

The diagnostic importance of lipases in the blood serum. A. KÖRBYNER. *Deut. Arch. klin. Med.* 155, 353-9(1927) --In various diseases of the liver, pancreas, kidneys, lungs, blood and in other pathol. conditions, only normal lipases were found in the blood serum. P. Y. JACKSON

The effect of colloidal dyes upon the vitality of leucocytes. E. V. PHILIPSBORN. *Deut. Arch. klin. Med.* 155, 281-93(1927) --Leucocytes in the urine are rapidly affected by bacterial toxins so that they are readily stained. Variations of the temp. between 15° and 37°, or of the p_H (by the addn. of HCl or NaOH) between the limits found in fresh urine, or of illumination, did not affect the ability of the leucocytes to resist staining. When fresh leucocytes from the blood are kept at 37° in blood serum, in 0.9% NaCl, or in urine, it is found after 30 min. that only a few in each lot are readily stained by Seydewitz's soln., and only those in the urine are strongly stained. After 30 hrs. 0.75 of the serum leucocytes will stain; those in the other solns. are all stained, but only those in the urine are strongly colored and in good condition. The presence in the urine of many fresh leucocytes which resist staining is an indication of acute inflammation of the bladder, kidneys, or ureter. The death of the leucocytes is not sufficient to cause them to stain; the structure of the cell must be altered, as is shown by the fact that warming for 30 min. with quinine, a typical protoplasm-poison, is sufficient to cause practically all the leucocytes to stain. P. Y. JACKSON

The relation of high blood pressure to hyperglucemia. HANS VORGELIN. *Deut. Arch. klin. Med.* 156, 178-81(1927) --A soln. of 20 g. glucose in 100 cc. water, taken on an empty stomach, causes in normal individuals a rise in blood sugar of about 70%; the max. is found in 45-60 min., and after 90-120 min. normal or subnormal values are found. Patients with high blood pressure, including those with chronic nephritis, secondary and genuine shrunken kidney, and arteriosclerosis, were examd., and in all cases the curve for the concn. of blood sugar after the administration of glucose by mouth was found to be within the normal limits. P. Y. JACKSON

Sodium-chlorine regulation. Clinical investigation of the role of sodium and

chlorine ions in the regulation of acid-base equilibrium. LUDWIG HEILMEYER. *Deut. Arch. klin. Med.* 156, 200-25(1927).—Corresponding to 130 mille-equiv. of Na ion, there is found in the blood serum only 5 mille-equiv. each of K and Ca, and 2 mille-equiv. Mg. Of the anions, there is found for 100 mille-equiv. Cl, 2 of phosphate and 13 carbonate (or bicarbonate). More than 400 cases reported in the literature were studied to det. the greatest variations in these ratios occasioned by diseases of various kinds, by radiation with x-rays or with ultra-violet light, by injection of choline or adrenaline, by intravenous or per oral administration of NH_4Cl , CaCl_2 , NaHCO_3 , etc. The abs. variations were large only for Na ion and Cl ion; for Na, max. 222 mille-equiv.; min. 94.8; for Cl, max. 118, min. 48. The variations among the "smaller" ions were largely compensated; that is, an increase in K is frequently accompanied by a decrease in Ca; and further, especially in very severe nephritis, by an increase in phosphate. Of 290 cases there were 284 where the sum $\text{K} + \text{Ca}$ varied not more than 3.5 mille-equiv. from the av. 10.6. Still more nearly const. is the term $\text{K} + \text{Ca} - \text{P}$; its mean in 100 cases was 9.1 mille-equiv.; these included extreme cases of disturbances of the acid-base equil., a stomach tetany with an alk. reserve of 117.4 vol. % CO_2 , and a diabetic coma with an alk. reserve of only 4.4 vol. %. It follows that only the Na and Cl ions, together with proteins and org. acids, det. the amt. of the alk. reserve; and that pathological variations result only from foreign org. acids, decompn. products of proteins and changes in the concn. of Na or Cl ions. The Henderson equation becomes $(\text{H-ion}) = (\text{free } \text{CO}_2) / (\text{Na} + k - \text{Cl-anion deficit})$, where $k = \text{K} + \text{Ca} - \text{P}$. The respiration det. the numerator in this equation, so that the ratio is kept const. for any change in the denominator. The Na and Cl ion concns. det. the denominator; and their effect is noted in cases of diabetic, uremic, or cholamic coma, where excess acid has exhausted the alk. reserve. When the respiration is disturbed, as in pneumonia, the acidosis is compensated by the regulation of Na and Cl ions. P. Y. JACKSON

Further work on paroxysmal hemoglobinuria. T. KUMAGAI AND M. NAMBA. *Deut. Arch. klin. Med.* 156, 257-71(1927).—In Japan typical hemoglobinuria is more common than in European countries or in America, and is frequently found assoc. with syphilis. It is possible that a tendency to this condition is a racial trait. Persons with a strong autohemolytic reaction develop hemoglobinuria upon immersion of the feet in ice water; less pronounced autohemolysis responds with albuminuria to the same conditions. Autohemolytics are most frequently found in the fourth blood group. P. Y. JACKSON

Paroxysmal uroerythrinuria. MUTSUMI NAMBA. *Deut. Arch. klin. Med.* 156, 272-82(1927).—Uroerythrin, instead of the expected hemoglobin, was found in the urine of a no. of autohemolytic patients; and in paroxysmal hemoglobinuria, uroerythrin was detected along with urobilin. The uroerythrin was apparently a product of the hemoglobin. P. Y. JACKSON

The chemical constitution of the kidneys in disease, and its relation to anatomical and clinical observations. I. G. HOPPE-SEYLER. *Deut. Arch. klin. Med.* 156, 321-42(1927).—Tables are given to show the gross wt., dry wt., water, coagulable protein, total N, residue N, fat and ash for normal kidneys and for kidneys in various pathological conditions. II. *Ibid* 159, 31-5(1928).—Normal kidneys contained 81% water, 13.9% coagulable protein, 5% N, 2% fat and 8% ash. In disease of the liver the total wt. is increased, and usually the dry wt. also. In some pathological states the protein content is lower, as in older cases of diabetes, and especially in arteriosclerotic shrinking, where sometimes protein, fat and N are all far below normal. P. Y. J.

The ion content of the blood in diseases of the heart. WERNER BURGER. *Deut. Arch. klin. Med.* 159, 79-84(1928).—The av. concn. of Na, K and Ca in the blood of a patient suffering with heart disease was not abnormal. When a milk diet was employed there was a decrease in the concn. of Na and an increase in K and Ca; but the variations were too small to be considered of importance. P. Y. JACKSON

The lactic acid content of the blood following the injection of lactic acid in experimental derangement of the liver. K. BECKMANN AND T. MIRSALIS. *Deut. Arch. klin. Med.* 159, 129-46(1928); cf. *C. A.* 22, 625.—In normal dogs the intravenous or oral administration of Ca lactate was followed by no increase in the lactic acid content of the blood. After several 0.1 g. doses of P, given as an emulsion in oil, the injection of Ca lactate was followed by an immediate and large increase in blood lactic acid; the concn. did not revert to normal, but to a value somewhat greater than that detd. before the injection. Similar results were noted after the administration of Am and Et alcs. No special increase in concn. was observed in any case after the oral administration of lactic acid. The rate at which the excess lactic acid disappeared from the blood depended upon the extent to which the liver was deranged by the poison administered.

A decrease in the Ca content of the serum was noted in a case of severe derangement.

P. Y. JACKSON

A method for the determination of hexosephosphoric acids in the blood; and a study of their occurrence in normal and diabetic organisms. HEINZ LAWACZECK. *Deut. Arch. klin. Med.* 159, 223-34(1928).—The blood to be analyzed is twice treated with HgCl_2 to ppt. proteins, and the excess Hg removed with H_2S ; the hexosephosphoric acids are not combined with protein and none is lost by this process. The clear filtrate is made alk., and the hexosephosphoric acid pptd. with $\text{Ba}(\text{OH})_2$; washed with dil. $\text{Ba}(\text{OH})_2$ soln., dissolved in HCl, and freed from Ba by pptn. of the latter as BaSO_4 . The hexose sugars are then directly detd. in the neutralized mixt. by the micro-reduction method of Bang. The reducing sugar is calcd. as glucose; the error is small and const. In non-diabetics the blood contains about 1 mg. % of hexosephosphoric acid; or about 1% of the glucose is combined with about 1-3% of the total phosphoric acid in the blood. In diabetics the av. concn. of hexosephosphoric acid is slightly higher. No relation was found between the concn. of hexosephosphoric acid and the total concn. of blood sugar in diabetics.

P. Y. JACKSON

A typical diabetic coma. THEODOR WEISS. *Deut. Arch. klin. Med.* 159, 235-40 (1928).—A case is discussed in which diabetic coma was attended by only very slight ketonuria, but by a very high concn. of blood sugar (1245 mg. in 100 cc.). P. Y. J.

The administration of acid and base as a test of kidney function. FERDINAND LEBERMANN. *Deut. Arch. klin. Med.* 159, 241-5(1928).—The p_{H} of the urine of a person with sound heart and kidneys falls immediately after the administration of HCl, within 1.5 hrs. a dose of 10 cc. 10% HCl in 300 cc. H_2O , given on an empty stomach, depresses the p_{H} below 6. If after 2 hrs. 15 g. Na_2CO_3 , dissolved in 300 cc. H_2O , is swallowed, the p_{H} of the urine rapidly rises to approx. 8. In light cases of glomerulo-nephritis the behavior is almost the same as in normal persons; but in acute nephritis or cases of shrunken kidney, the p_{H} remains almost const. and on the acid side of neutrality. This detn. is of value in the diagnosis of pathol. conditions of the kidneys. P. Y. J.

The acidity of the duodenum and of the upper small intestine. ÉMIL GOTSCHLICK. *Deut. Arch. klin. Med.* 159, 288-305(1928).—In a majority of cases of healthy persons, or those convalescing from a disease which did not involve the digestive tract, the duodenal reaction was distinctly acid. In other cases a relatively strong alk. reaction was found. The reaction in the upper small intestine was normal in cases of subacidity, anacidity and achylia. The acidity of the duodenum and of the small intestine is increased only slightly and for only 10-15 min. by the administration of dilute HCl by mouth. After rather large doses of HCl the temporary acidity is followed by a temporary alkalinity in both duodenum and upper small intestine. The colorimetric method of detn. was employed.

P. Y. JACKSON

The antigenic properties of papain-digested bacterial antigens. HIDETAKI YAOI AND KAMEKICHI NAGASE. Govt. Inst. for Infectious Diseases, Tokyo. *Japan. Med. World* 8, 86-90(1928).—Expts. on dysentery and typhoid bacilli show that papain digests of bacteria act as excellent antigens to test for the presence in serum of agglutinin-producing substances, as well as for passive and active immunization. By using papain digests it is possible to obtain active antigens free from bacterial bodies.

N. KOPELOFF

The significance of lipoids in biology and medicine. LAJOS SURANYI. Univ. of Budapest. *Z. Immunitäts.* 53, 74-98(1927).—Daily feeding of cholesterol causes a lymphocytosis while lecithin produces a neutrophilia. Immunization combined with cholesterol feeding results in a higher titer of antibodies while lecithin causes a lower titer. Sensitized guinea pigs can be saved from fatal anaphylactic shock when the shock-producing dose is reinjected mixed with cholesterol. A single or several fatal doses of diphtheria toxin do not kill a guinea pig when injected with cholesterol. Cholesterol feeding lowers the complement titer. Such procedures as narcosis which cause a hypercholesterolemia also cause a leucocytosis, decrease of complement and hyperglucemia. Lecithin fed to and typhoid bacilli injected into rabbits lower the sedimentation speed of red cells. Cholesterol has this same action but to a less extent. Cholesterol fed for 3 months produces atheromatosis in rabbits. There is also a great increase in the general fat deposits.

J. H. LEWIS

The antigenic action of bacterial lipoids. M. FISLER AND S. EHRLICH. Staatlichen serotherapeutischen Inst., Wien. *Z. Immunitäts.* 53, 151-69(1927); cf. C. A. 21, 1674.—The intravenous injection of the 80% alc.-sol. ext. from dried typhoid bacilli or cholera vibrios, either with or without the residue, does not produce agglutinins, bacteriolysins or Forssman's antibody in rabbits. However the sera produced gives complement fixation reactions with the lipid exts. If the lipid is injected with guinea

pig serum the titer for the complement fixation reaction is increased. There was some specificity of the antibodies produced but was rather spread out. The antiserum had no influence on the native bacteria and bacteria immune serum gave no reaction with the lipid. Lipoid antisera gave flocculation reactions with alc. bacterial exts. but were entirely unsp.

JULIAN H. LEWIS

The antigenic function of bacterial lipoids. A. KLOPSTOCK AND E. WITKESKY. *Z. Immunitäts.* 53, 170-91(1927).—Rabbits injected with killed tubercle bacilli produced antisera which gave complement-fixation reactions with tubercle bacilli as well as with the lipoids from these organisms. This serum contained, besides the sp. antibodies for tubercle bacilli lipoids, also antibodies which reacted with a wide range of lipoids. *Proteus* X-19 bacilli formed antibodies which were active only against the native bacteria and not the alc. ext. Anti-lipoid bodies were obtained by injecting the lipid from tubercle and *Proteus* X-19 bacilli without mixing with a protein. Anti-tubercle bacillus lipid serum acts on native tubercle bacilli while antisera to defatted bacilli reacted only with native bacilli. The same is true for the *Proteus* X-19 bacilli. The antisera to the lipoids of these 2 organisms are very unsp. in their reactions with lipoids.

JULIAN H. LEWIS

Antibody formation among animals. L. HIRZFELD AND HALBER. Staatlichen Inst. f. Hyg., Warshaw. *Z. Immunitäts.* 53, 419-38(1927).—This is a further analysis (*Z. Immunitäts.* 48, 33(1926)) of the finding that the injection of rabbits with group A human blood produces sheep blood hemolysis, while only in a few cases does the injection of sheep blood produce an anti-A antiserum. The ability of an animal to form antibodies for a second substance after the injection of another substance, although the 2 substances have no demonstrable antigen in common, is a rather common phenomenon. A theory to explain this unsp. formation of antibodies is given which is based on the conception that natural antibodies occur at different stages of maturity and that they respond differently to stimuli.

JULIAN H. LEWIS

The extraction and fractionation of Wassermann positive sera. L. REINER AND M. TÖRÖK. Hyg. Inst., Elizabeth-Universität. *Z. Immunitäts.* 53, 532-40(1927).—Serum lipoids play no important role in the fixation of complement in the Wassermann reaction. Electrodialysis ppts. completely the Wassermann reacting substances, but they are not bound to euglobulin. The ppt. contains a small portion of the pseudoglobulin which gives the same Wassermann reaction of the original serum.

J. H. L.

The Wassermann reaction after immunizing with autogenous lipid. E. HERONIMUS AND W. AWRECH. Bakteriolog. Inst. der 2. Univ., Moskau. *Z. Immunitäts.* 53, 541-6(1927).—Sachs and coworkers believe that the antigen of the Wassermann reaction antibodies is the lipid of syphilitic disintegrated tissues combined with the protein of the spirochetes. Expts. to confirm this theory have previously been made with rabbits although this animal is very unsatisfactory since it responds to unsp. stimuli with the formation of a positive Wassermann reaction. Rats immunized with an alc. ext. of rat kidneys mixed with hog serum did not produce a positive reaction although they were able to form complement-fixation antibodies for the alc. ext. of horse kidney.

JULIAN H. LEWIS

The fermentative method of producing diphtheria toxin in vitro. V. M. SDRAVOS-MISSLOV AND N. E. KOSTROMIN. Bakteriolog. Inst., Perm. *Z. Immunitäts.* 54, 1-20 (1927).—It is believed that antibodies are none other than combinations of antigen and enzyme with a resulting "ungrouping." Trypsin mixed with diphtheria toxin under certain conditions produced an antiserum which had all the properties of that produced by animal immunization. In infection of the body there is a balance between the production of enzymes and the antienzyme action of the antigen which determines the outcome of the disease. The indication is given that enzyme administration might be helpful in the treatment of disease.

JULIAN H. LEWIS

The experimental basis of the protection afforded by toxoids. ST. BÄCHER. Serotherapeutischen Inst., Wien. *Z. Immunitäts.* 54, 21-40(1927).—A review of the recent work on toxoid, especially the anatoxin of Ramon.

JULIAN H. LEWIS

The relation of lipid antibodies in the fractionation of serum by acid precipitation. G. E. SELTER. Inst. für experimentelle Krebsforschung, Heidelberg. *Z. Immunitäts.* 54, 113-30(1927).—Antiserum produced by immunizing with lecithin or non-heterogeneous organ exts. and hog serum was fractionated with dil. HCl. The lecithin antibodies appeared in the globulin fraction and the hog serum antibodies appeared in the albumin fraction. However, heterogeneous lipid antibodies were found in the albumin fraction. To explain this difference the theory is given that the native lipid of the globulin fraction is liberated by the acid used for fractionation and reacts with the lipid antibodies. The reaction product is pptd. with the globulins. That no inhi-

bition of antibody reaction is observed is explained in that the combination is a very weak one and is readily broken up. The fact that in the fractionation of a mixt. of a heterogeneous lipid antiserum and a blood serum of a heterogeneous animal the heterogeneous as well as the other lipid antibodies appear in the globulin fraction is given as a fact to support the above theory. An exception to the rule is that of anti-brain serum whose antilipoid reacting bodies are pptd. in the globulin fraction.

JULIAN H. LEWIS

Isoagglutinins and group specific lipoids. I. WITEBSKY AND K. OKABE. Institut. für Krebsforschung, Heidelberg. *Z. Immunitäts.* **54**, 131-7(1927); cf. *C. A.* **22**, 2406.—Complement-fixation and pptn. expts. show no relation between antisera to group sp. red cells and the lipoids from these cells. However, such a relation can be shown by absorption expts. Agglutinin α can be absorbed from serum by the alc. ext. of red cells of group a, and agglutinin in β by the alc. ext. of group b red cells. From serum of group O either agglutinin α or β can be removed by the alc. ext. of the corresponding red cells.

JULIAN H. LEWIS

The relation of blood coagulation to anaphylactic shock. HANS LOEWENTHAL. Rudolf Virchow-Krankenhaus, Berlin. *Z. Immunitäts.* **54**, 138-43(1927).—Anaphylactic shock in sensitized guinea pigs whose blood is made uncoagulable with heparin differs in no way from the usual type of anaphylactic shock.

JULIAN H. LEWIS

Lysozyme of egg white. T. KIGASAWA. Inst. der deut. Univ., Prag. *Z. Immunitäts.* **54**, 155-80(1927).—Lysozyme, a substance which occurs widespread in the fluids and tissues of the body and of plants rapidly dissolves many forms of non-pathogenic bacteria. Egg white will completely dissolve a thick suspension of certain air bacteria in a short time at 37° or 42°. Not all air bacteria are sensitive to lysozyme and among those that are sensitive there is a great variation. The bacteria that are acted on are Gram positive. Lysozyme of egg white is more resistant to heat than is bacteriolysin of serum, but is nevertheless gradually destroyed by high temps. The bacteria vary in their soly. after heating. Some strains can be dissolved by lysozyme after boiling, while others lose their sensitivity after heating to much lower temps. A lysozyme that has dissolved bacteria once may do so a 2nd and a 3rd time, but there finally comes an exhaustion, the time of appearance of which depends on the species of bacteria. To a given amt. of lysozyme a large enough amt. of bacteria can be added that some remain undissolved. It is impossible to bind lysozyme to bacteria without at the same time producing some lysis. Free alkali within certain limits inhibits lysozyme, but does not make it, with the concns. tried, impossible to act. Free acid above a certain limit inhibits concd. as well as dil. lysozyme. A clear soln. of bacteria dissolved with lysozyme is made turbid with those concns. of acid which inhibit lysis. Suspensions in which lysis is inhibited by acid become immediately clear on over neutralization with alkali. This action of alkali is obtained with bacteria washed free of acid and lysozyme. Bacteria that are prevented from dissolving because they were heated are dissolved by alkali. Without knowing the nature of lysozyme it is a substance which makes bacteria sensitive to changes in Ph.

JULIAN H. LEWIS

The production of group specific antibodies for human red blood cells. I. WITEBSKY AND K. OKABE. Inst. für experimentelle Krebsforschung, Heidelberg. *Z. Immunitäts.* **54**, 181-8(1927).—The intraperitoneal injection of guinea pigs with human red blood cells of group A produces lipid antibodies which give complement fixation reactions with the alc. ext. of red cells of group A. Such antiserum does not react with the Forssman antigen in contrast to the antiserum produced in rabbits the same way. The antiserum for group A was sp. for this blood group although the antiserum for the other groups was not. The antisera against group B and O red cells reacted only with red cells and not their lipoids. The injection of alc. ext. of human red blood cells combined with hog serum produced no lipid antibodies.

JULIAN H. LEWIS

Experiments with lysozyme. L. K. WOLFF. Pharmako therapeutischen Inst. Universitäts Amsterdam. *Z. Immunitäts.* **54**, 188-98(1927); cf. *C. A.* **21**, 251.—Lysozyme injected into animals disappears because of its soly. in lipoids. It is very difficult to ext. lysozyme from lipoids with H₂O. Very lipid-rich substances as egg yolk and fish roe contain much lysozyme which cannot be extd. with H₂O. If the lysozyme is absorbed by lecithin it can be brought into an aq. soln. by drying the lecithin with anhyd. Na₂SO₄ and extg. with MeOH. The lysozyme remains with the salt. The substance was further purified so that the amt. from 1 cc. egg-white weighed 1 mg.

JULIAN H. LEWIS

The mechanism of sensitization. V. A. BASHENIN. Inst. für Infektionskrankheiten "Elias Metschnikoff," Moskau. *Z. Immunitäts.* **54**, 226-36(1928).—The instantaneous removal of the site of injection of antigen in the guinea pig does not interfere

with anaphylactic sensitization. The sensitization is also not affected if the arterial or venous circulation is restricted. From these facts the conclusion is drawn that sensitization is a reflex action of the vegetative nervous system. JULIAN H. LEWIS

The relation of β -lysin to lipid solvents. ALFRED PETTERSSON. Karolinischen Inst., Stockholm. *Z. Immunitäts.* 54, 292-302(1928).—The bacteriolytic substance in sera which is resistant to heat at 56° and diln. with or dialysis against H₂O, as complement is, is called β -lysin. This substance is not injured by extg. the native or dried serum with ether, petroleum ether or CHCl₃, which is another mark of distinction from complement. The ppt. formed by treating serum with acetone contains no β -lysin. JULIAN H. LEWIS

The cellular nature of anaphylactic shock with erythrocytes as antigen. I. L. KRITCHEVSKII AND K. I. FRIEDE. Mikrobiol Forschungsinst., Moskau. *Z. Immunitäts.* 54, 303-12(1928).—Frogs sensitized with red blood cells and whose circulating blood was entirely replaced with Ringer-Locke's soln. showed anaphylactic shock when red cells were re injected just as if the antigen were serum. This expt. eliminated hemolysis and hemagglutination as a cause of shock with red cells and pointed to a cellular reaction instead of a humoral one. J. H. L.

Formation of antibodies in the spinal cavity. C GRABOW AND E. PLAUT. Landesheilanstalt, Neustadt i Holstein. *Z. Immunitäts.* 54, 335-54(1928).—Intraspinal immunization is not adapted to studying the local formation of antibodies because of irritation of the meninges and the formation of a depot of antigen. To neutralize this action a group of rabbits was immunized intravenously with one antigen and at the height of immunization was divided into 2 groups, one of which was given the same antigen intraspinally and the other another unrelated antigen but with equal irritative action. Conclusion: Antibodies are formed in the spinal canal independent of those in the serum. Points in the antibody curve showed a similarity to the condition in lues in which there is a high titer of Wassermann reagin in the spinal fluid without any being present in the serum, indicating that the Wassermann reagin is probably a true antibody. JULIAN H. LEWIS

Comparative studies with the spirochetal extract of Klopstock. HUGO HECHT. *Z. Immunitäts.* 54, 365-7(1928).—The spirochetal ext (probably lipoidal) made by Klopstock was excellent as a Wassermann antigen, but should always be controlled with other exts. JULIAN H. LEWIS

Antibody formation in tissue cultures. KURT MEYER AND HANS LOEWENTHAL. Rudolf Virchow-Krankenhaus, Berlin. *Z. Immunitäts.* 54, 409-19(1928).—Cultures of the spleen, lymph glands, and "milk-spots" of the omentum of rabbits regularly formed agglutinins for typhoid bacilli when the tissues were taken from animals previously immunized with typhoid bacilli or injected with them immediately before the cultures were made. Agglutinin formation was detectable first after 48 hrs., was at its highest in 3 days, and at 5 days agglutinin formation was no longer found. This quick cessation of function was attributed to the changes that the reticulo-endothelial cells undergo. Since cultures of the milk spots in the omentum consist of fibroblasts and reticulo-endothelial cells exclusively these expts. show for the first time the importance of these cells in antibody formation. MgCl₂ in the cultures did not increase antibody formation. **Anaphylaxis in tissue cultures.** *Ibid* 420-38.—Spleen and lymph gland from guinea pigs sensitized to horse serum were grown in a medium consisting of guinea pig plasma, spleen ext and horse serum in various dilns. No inhibition of growth was observed. It made no difference if normal or sensitized guinea pig plasma was used. The out-budding blood vessel endothelium seen in cultures of subcutaneous tissue and pia mater also showed no inhibition of growth under the same conditions. The same tissues were passively sensitized by growing 24 hrs. in plasma from sensitized guinea pigs, and, like actively sensitized tissues, there seemed to be no effect from the antigen in the medium. Tissues from guinea pigs dead of anaphylactic shock grew just as well as did those from normal guinea pigs. Heterogenetic serum prepd. by immunizing rabbits with guinea pig kidney had no effect on the growth of tissues or the rhythm of surviving pieces of embryonal heart other than that of normal rabbit serum. Various normal sera as well as rabbit serum had some inhibiting effect which was independent of the content in hemolysis. From these expts. it is concluded that the reticulo-endothelial cells, the blood vessel endothelial cells and heart muscle either do not take part in the anaphylactic shock or are so slightly injured that their growth remains unaffected. JULIAN H. LEWIS

The influence of chloralose on the anaphylactic reaction of guinea pig intestines. ARTHUR ELKELES. Rudolf Virchow-Krankenhaus, Berlin. *Z. Immunitäts.* 54, 471-7(1928).—Chloralose (a compd. of chloral hydrate and glucose) inhibits the anaphy-

lactic reaction of surviving guinea pig intestine in the concn. of 1:1000. When the chloralose soln. is replaced with pure Ringer soln. a typical anaphylactic response is obtained. The contractions from acetylcholine and hypophysin are only slightly inhibited. These expts. show that a narcotic has a peripheral as well as a central one.

JULIAN H. LEWIS

Anaphylactic antibody and precipitin. R. OTTO AND K. IWANOFF. Inst. "Robert Koch," Berlin. *Z. Immunitäts.* 54, 496-506(1928).—O. was not able to confirm his earlier findings (*Z. Hyg.* 103, 426(1924)) that the anaphylactic antibody and precipitin could be quantitatively sepd. by fractionation of antiserum. Only in some instances could this be done. In others the anaphylactic antibody was divided between euglobulin and pseudoglobulin while precipitin was entirely in the pseudoglobulin. In many sera both antibodies were in the same fraction, or both antibodies were divided between the 2 globulin fractions. The results did not agree with those of Doerr and Haßauer (*Z. Immunitäts.* 51, 463(1927)) who found by using electro-dialysis or electrodialfiltration that the 2 antibodies were either in both fractions, often quantitatively divided or in the euglobulin alone.

JULIAN H. LEWIS

The antigenic properties of brain lipoids. BORIS ABADJEFF. Inst. "Robert Koch," Berlin. *Z. Immunitäts* 54, 507-17(1928).—In contrast to the gray substance the white substance of the brain gave alc. exts. which were poor antigens for complement fixation and pptn. reactions in syphilis. There is no difference in the alc. ext. of normal and syphilitic (paralytic) brains in the ability to serve as antigens. There is no species specificity of brain alc. exts. as those from rabbits and guinea pigs act equally well as those from human brains. All sera from syphilitic paralysis gave positive reactions with brain exts., and also about $\frac{1}{3}$ of those from other stages of syphilis, independent of the presence of softening of the brain from other causes than syphilis. Brain exts. are sp. for syphilis as in no case did a serum which was negative with the usual Wassermann antigens give a positive reaction.

JULIAN H. LEWIS

Diabetes insipidus. II. Diuretic substance. HELEN BOURQUIN. Univ. S. Dak. *Am. J. Physiol.* 83, 125-33(1927); cf. *C. A.* 21, 1303.—A diuretic substance which was not pptd. by phosphotungstic acid was extd. from sections of the brains of dogs cut so as to include only the mammillary bodies. The substance was more abundant in the brains of dogs suffering from exptl. diabetic insipidus than in normal brains. The same or a similar diuretic substance was obtained from the blood of dogs suffering from diabetes insipidus but not from normal dogs blood. It could not be found in the urine.

J. F. LYMAN

The role of toxins in parathyroid tetany. I. An attempt to control tetany by the oral administration of kaolin. E. LARSON AND LEO A. ELKOURIE. Univ. of Alabama. *Am. J. Physiol.* 83, 231-6(1927).—The oral administration of kaolin to thyroparathyroidectomized dogs had no effect on preventing or controlling tetany.

J. F. L.

Experimental cretinism. I. A rachitic-like disturbance in extreme hypothyroidism. M. M. KUNDE AND A. J. CARLSON. Univ. of Chicago. *Am. J. Physiol.* 82, 630-8(1927).—When rabbits were thyroidectomized between 2 and 3 weeks after birth they suffered marked thyroid deficiency as shown by the growth curve and a pathol. condition corresponding to rickets in man which developed. This condition was accompanied by a severe anemia. Blood Ca was normal or slightly below normal; while the acid-sol. P of the serum was low.

J. F. LYMAN

Experimental investigations on the serum-antigen reaction. MARIO CAPOACCIA AND GOFFREDO FROLA. *Boll. soc. ital. biol. sper.* 3, 178-82(1928).—The specificity and sensitiveness of the serum-antigen reaction were studied. Guinea pigs were injected with small doses of $HgCl_2$. The reaction was positive with kidney tissue antigen. Animals treated with phosphorated oil gave a positive reaction with liver antigen. Disintegration products of various organs when injected into animals and their blood tested with the various antigens always gave a positive reaction with the corresponding antigen. Many other organs used as antigens are cited.

PETER MASUCCI

Studies in blood volume with the dye method. LEONARD G. ROWNTREE. Mayo Foundation, Rochester, Minn. *Ann. Internal Med.* 1, 890-901(1928).—The use of the dye (Congo red or vital red) is sufficiently accurate for clinical purposes and free from danger.

JOHN T. MYERS

Clinical and pathological evidence of the influence of iodine in the therapy of primary hyperthyroidism. FRANK R. MENNE, THOMAS M. JOYCE AND JAMES D. STEWART. Univ. of Oregon, Portland. *Ann. Internal Med.* 1, 912-34(1928).—Intra-acinar colloid storage with a physico-chem. and mech. inhibition of secretory function and power is probably as important as explanation of the action of I as is the complete iodination of the hormone. The permanency of the efficacious use of I can only be

detd. by more exptl. studies of its real role in colloid storage and in maintaining metabolic constancy.

JOHN T. MYERS

Studies in intestinal obstruction. II. The absorption of histamine from the obstructed bowel. OWEN H. WANGENSTEEN AND MILE LOUCKS. Univ. of Minn. *Arch. Surg.* 16, 1089-1111(1928).—Absorption of histamine from the normal small intestine of the dog in simple obstruction of 2 days' standing cannot be detected. In strangulation, a great fall in arterial blood pressure follows the release of the strangulating mechanism. The autolysis of intestinal mucosa deprived of blood supply is rapid and accompanied by the liberation of a toxic substance with an effect like that of histamine. Absorption of histamine from a strangulated segment that is still viable does not appear great. **III. Simple obstruction: a study of the cause of death in mechanical obstruction of the upper part of the intestine.** OWEN H. WANGENSTEEN AND STANLEY S. CHUNN. *Ibid* 1242-55.—The rapid death of dogs with upper intestinal obstruction is due to rapid dehydration and loss of chlorides. Saline soln. in treatment merely replaces these substances, it does not detoxify. There is no evidence of the absorption of toxins. Interference with the continuity of the upper intestine causes an increase in blood non-protein N, and a decrease in chlorides. The urinary N increases. The administration of NaCl prevents the blood but not the urine changes.

JOHN T. MYERS

Investigations on complement. I. The influence of various salts on the action of complement. H. TOKUNAGA. Epidemiological Inst. Jamaguchi, Japan. *Centr. Bakt. Parasitenk., I. Abt. Orig.* 107, 283-8(1928).—The action of guinea-pig complement on sensitized goat erythrocytes can be changed by several hypertonic and isotonic salt solns. Ba salts, NaNO_3 and MgSO_4 have a marked inhibiting effect, which cannot be offset by an increase of amboceptor or complement. Cl , NO_3 and SO_4 and salts of Na or K have only a slight inhibiting action. Isotonic NaOAc or KOAc markedly enhance the action, the unit ranging from 0.006125 to 0.0125 cc. for guinea-pig serum which was almost inactive with isotonic NaCl. **II. The value of potassium acetate solutions in complement reactions.** *Ibid* 288-95.—The use of KOAc will offset the action of small quantities of anticomplementary salts. Guinea-pig serum inactivated with $(\text{NH}_4)_2\text{SO}_4$ can be reactivated with 0.0001 cc. of normal guinea-pig serum in the presence of isotonic KOAc. Apparently KOAc favors the action of the third component of complement. In the presence of isotonic KOAc, rabbit and human serum is strongly hemolytic for goat erythrocytes. The substitution of isotonic KOAc for NaCl renders the Wassermann reaction more sensitive.

JOHN T. MYERS

The non-specific Wassermann reaction in rabbits. Y. MANO. Kaiser Wilhelm Inst Biochem. Berlin. *Centr. Bakt. Parasitenk., I Abt. Orig.* 107, 306-8(1928).—The use of antisyphilitic medication as arsphenamine or Hg has no uniform effect. Parenteral injection of lipoids was without influence except that large amts. of lecithin cause a transitory disappearance of the positive reaction.

JOHN T. MYERS

The influence of thermochemical stimulation on the Arneth blood picture in the human and in normal animals. B. G. RUBINSTEIN. Odessa Therapeutic Inst. *Folia Hematol.* 36, 5-11(1928).

JOHN T. MYERS

The erythrocyte membrane as a colloidal system, and its changes. O. B. LEPRSHINSKII. Timirjaseff State Inst., Moscow. *Folia Hematol.* 36, 41-93(1928).—The processes of adsorption, swelling, coagulation and disintegration, on the part of frog erythrocytes under the influence of various chem. agents, were observed under the microscope. The cell membrane behaves like a colloidal protein, being insol. in water and sol. in acids and alkalis. It is probably fibrin. The observations on swelling, soln. and fibrin pptn. suggest that the fibrin of serum is a postmortem product of erythrocyte membranes, the amt. in living blood being small and dependent on physico-chem. conditions. Coagulation depends on similar changes, an increase in the degree of dispersion leading toward sol. formation, and a decrease toward coagulation. In many preps. it was possible to see the transformation of cell membrane and then cell nucleus into fine threads. The cell membrane is very sensitive to changes in p_H or salt content in the surrounding medium. This may explain poikilocytosis in the anemias. The application of AcOH produces basophilic granules resembling polychromatophilia. The vol. of the cells is least at the isoelec. point. The process of agglutination is due to swelling of the cell membrane and depends on mol. forces. Strychnine nitrate, 0.15:1000 Ringer's soln. contg. K mixed with blood and 1% tannin soln. produced a ppt. in the cells resembling granules. This did not occur with 5% tannin. JOHN T. MYERS

Hydatid fluid as an anaphylactic antigen. C. H. KELLAWAY. Walter and Eliza Hall Inst., Melbourne. *J. Path. Bact.* 31, 141-56(1928).—The presence of host serum protein in most samples of hydatid fluid is shown by the use of the isolated guinea-

pig uterus. This does not prove its presence *in vivo*, since it is almost impossible to remove fluid from a cyst without contact with the adventitia, and while mother and daughter cysts *in vitro* are permeable to dyes of low mol. wt., they are not readily permeable to oxyhemoglobin or to serum protein. In addn. to host serum proteins another anaphylactic antigen is present in hydatid fluid. This was demonstrated by using coned hydatid fluid of several species, by distn. *in vacuo* or by ultra-filtration. Bicarbonate Ringer solns. which are being oxygenated may be kept at a constant p_H with a const. partial pressure of CO_2 .

JOHN T. MYERS

A case of nervous cretinism with histological examination of the organs. ELIZABETH COWPER, EAVES AND MARGARET MARY CROLL. South Yorkshire Mental Hosp., Wadsley, Sheffield, England. *J. Path. Bact.* **31**, 163 72(1928) — Microchem. reactions for fat were pos. in the cells of most organs. It was in many instances a fatty pigment, but not all pigment was lipid. In the spleen there is a very intense microchem. reaction for Fe, but some of the pigment did not contain any. In the central nervous system, and in the walls of the vessels of the corpus striatum, Fe was found but not necessarily as a pigment. It is remarkable that Fe was absent in the pigment in the liver. Ca was deposited irregularly in the bone. There was more than a normal amt. in the central nervous system, which may have resulted from an increase in the thickened vessel walls where the purpurin reaction was positive. The myelinization of the brain tracts corresponded to that at birth. This arrest of myelinization may account for a low P content of the brain.

JOHN T. MYERS

Hypercholesterolemic splenomegaly. S. C. DYKE. Wolverhampton and Staffordshire Hosp., Wolverhampton, England. *J. Path. Bact.* **31**, 173 84(1928) — A case of splenomegaly associated with generalized xanthoma, hypercholesterolemia, and biliary cirrhosis is described. The hypercholesterolemia was due to chronic interstitial pancreatitis. The splenomegaly was due to hyperplasia of large mononuclear cells of reticulo-endothelial origin. Histological methods did not reveal cytoplasmic inclusions of fatty or lipid material in these cells.

JOHN T. MYERS

Experiments upon the relationship of complement fixation to precipitation. NEIL E. GOLDSWORTHY. Univ. of Cambridge. *J. Path. Bact.* **31**, 220 35(1928) — The process of pptn. may be divided into 3 phases, first clear, second opalescence and turbidity and third particulation or true pptn. Complement fixation occurs during the early phases. Both processes are dependent on proportions in which antigen and antibody are present and the potency of the antiserum. A mixt. of antigen and antiserum in optimal proportions for particulation quickly reaches the peak of its complement-binding capacity and is soon beyond that point, after which the amt. of complement fixed is practically nil. If either antigen or antibody is in relative excess, maximal complement-fixing power is attained more slowly. Mixts. with only a moderate excess of antigen retain opalescence and complement-binding power in a remarkable way. Complement fixation is a function of the size of the particle of the ppt. J. T. MYERS

The immunity index method of testing antigenic values. A. T. GLENNY AND HILDA WADDINGTON. Wellcome Lab., Breckenham, Kent. *J. Path. Bact.* **31**, 403 21(1928).—Guinea pigs may become Schick-negative after the eighth weekly injection of toxin. Immunization is more rapid when begun in summer or early fall, and if the health of the animal is good. Qual. differences exist between different batches of toxoid depending on the amt. of precipitable material, the type of broth, the amt. of HCHO and the absence of phenol. Toxoid pptd. at p_H 0.2 is still antigenic, as is also Na ricinoleate toxoid. The addn. of alum, turpentine, or toluene increases the antigenic efficiency of toxoid. The antigenic efficiency of toxin-antitoxin and of toxoid-antitoxin is increased by heating the floccules to 70° for 1 hr. The immunity response is increased by heating the floccules to 70° for 1 hr. The immunity response to one antigen may be lowered by simultaneous response to other antigens. Dye-blockaded pigs show little response. Diln. of toxin-antitoxin mixts. causes dissoen.

JOHN T. MYERS

The precipitation test in hydatid infestation. NEIL E. GOLDSWORTHY. Univ. of Cambridge. *J. Path. Bact.* **31**, 435 6(1928).—Particular attention must be paid to optimal proportions.

JOHN T. MYERS

Studies of an insulin-resistant diabetic. R. D. LAWRENCE. Kings College Hosp. Quart. *J. Med.* **21**, 359 69(1928).—A boy of 17 suddenly developed diabetes 3 years ago. It was controlled by 40 units of insulin per day and a diet of 35 g. carbohydrate, 38 g. protein, and 83 g. fat, the fall in blood sugar being normal. A year later he required 100 units on the same diet, and 6 months later he was excreting 5 to 10 g. sugar on a diet of 60 g. carbohydrate, 80 g. protein, and 150 g. fat, with 220 units of insulin per day, a glucose equiv. of 1 g. per 2 units. When insulin was omitted he went into coma; hence it has a mild action. None of the usual factors such as sepsis, which

make a patient insulin resistant, was present. Blood sugar studies showed features different from the ordinary severe diabetic. It was lowest after a night's rest, and when carbohydrate was given it rose in spite of insulin. This was not due to delayed insulin action or lack of absorption because insulin during fasting reduced the blood sugar at a normal rate, though to a less degree than in the ordinary diabetic. It seems that insulin in this case cannot deal with ingested carbohydrate in the usual way, by storing it as glycogen. When starved the blood sugar fell spontaneously instead of rising as in the usual diabetic, when insulin is withheld. It is suggested that insulin here failed to store glycogen normally, but did have its other action of checking the new formation of sugar and ketones from endogenous protein and fat. It seems probable that a factor other than insulin is lacking, perhaps some coenzyme which is necessary in the usual action of insulin in forming glycogen.

JOHN T. MYERS

Observations on the pulmonary ventilation and oxygen consumption in pulmonary tuberculosis, and on the effect of the respiratory quotient on the relation between pulmonary ventilation and oxygen consumption. RAYMOND WILLIAMSON. Hospital for Consumption and Diseases of the Chest, Brompton, England. *Quart. J. Med.* 21, 371-83(1928).—O consumption and pulmonary ventilation in patients with pulmonary tuberculosis when examd. over a considerable period under basal conditions vary together. Even under varying conditions, the relationship is approx. direct. In a normal subject there was a close relationship under basal, but not under varied conditions, being modified considerably by the respiratory quotient. For practical purposes the relationship between O consumption and pulmonary ventilation seems sufficiently close to permit the assumption that the measure of pulmonary ventilation indicates the rate of metabolism, and may be useful in following the progress of a case of pulmonary tuberculosis.

JOHN T. MYERS

Creatine and rigidity. MARION HIRST AND C. G. IMRIE. Univ. of Sheffield. *Quart. J. Med.* 21, 401-17(1928).—In subjects with marked Parkinsonian rigidity creatinurea occurs regularly. The amt. excreted expressed as a fraction of the body wt. appears to be related to the body rigidity. The rate of excretion is lowest at night when muscular activity is least. In these respects it resembles the output of uric acid, both in these cases and in the normal subject. After single doses of creatine (18 g.) rigid cases excrete less of the injected material than do normal persons. When 3 such doses are given on successive days, the output was greater after the second and third doses in both normal and rigid cases but the difference was greater in the latter. In some cases the creatine seemed to be broken down. Creatine in large doses increases the output of creatinine.

JOHN T. MYERS

Variations in the different forms of phosphorus under the influence of diabetes and the hypoglycemic drugs. G. FLORENCE, J. EISELME and TSEN ZOLA. *Bull. soc. chim. biol.* 10, 675-83(1928).—In the diabetic there is a diminution of saline P in the plasma but an increase in the org. P. The etherized P is increased 7 times and the remaining org. P is doubled. In the diabetic as in the normal animal, insulin and synthalin tend to restore the P of the blood to its normal value by increasing the saline P and diminishing the etherized and other org. P. There appears to be no action on the lipidic P. In the muscles insulin and synthalin, on the contrary, decrease the saline P and increase the org. P.

L. W. RIGGS

Comparative action of a precipitating serum upon the serums of the mother and fetus. L. NATTAN-LARRIER AND P. LÉPINÉ. *Compt. rend. soc. biol.* 98, 924-6(1928); cf. *C. A.* 22, 620.—In 40% of the subjects the serum of the fetus appeared less active and less sp. than the maternal serum. The results of this study tend to support the idea that proteins of the normal maternal serum do not traverse the placental tissue. Antimaternal precipitins in fetal blood and antifetal precipitins in maternal blood. *Ibid* 926-8.—In 12 cases the fetal serum gave no ppt. in the corresponding maternal serum, and in turn the maternal blood gave no ppt. in the serum of the fetal homolog.

L. W. RIGGS

Hemolysis and surface tension. AUGUSTE LUMIÈRE AND EDOUARD RÉTIF. *Compt. rend. soc. biol.* 98, 984-5(1928).—Blood of the guinea pig, withdrawn by cardiac puncture, was dild. to 1 in 50 with physiol. saline soln. and to this dild. was added just sufficient of the active substance to insure hemolysis. The surface tension of the mixt. was then detd. The most active hemolysins such as saponin and hexylresorcinol in 1/20,000 gave solns. with a surface tension of 65 and 59 dynes per cm., resp., while the com. products "Nokal A. E. M." and "Alborit" in concns. of 1 in 600 and 1 in 250, resp., caused the surface tension to drop to 40 and 49, resp. Accordingly there is no relation between lowering of the surface tension and hemolytic power.

L. W. RIGGS

Role of arsenic in tar cancer. SIMONS RAPOSO. *Compt. rend. soc. biol.* 98,

997-9(1928).—The application of Fowler's soln. or of As_2O_3 to surfaces previously painted with tar appeared to have little or no effect on the development of cancer. Thorough washing of the tar prevented the formation of cancer. Pseudo-electrolysis of tar (Kotzareff method) and the action of heat on cancer-forming tar. *Ibid* 999-1001; cf. Kotzareff, *C. A.* 21, 268.—Tar applied at 10° to 45 rabbits caused no cancer in 70 days. When applied at 55° 9 of the animals developed cancer. Results with pseudo-electrolyzed tar were like those with heated tar. There was no difference in the development of cancer following daily paintings and paintings twice a week. L. W. R.

Retention of residual nitrogen and of aromatic substances of the blood. Anatomic localization in experimental renal insufficiency. M. FRANK. *Compt. rend. soc. biol.* 98, 1053-7(1928).—In exptl. renal insufficiency in the dog, the raised level of residual N and of aromatic substances are symptoms of a grave renal condition involving an important lesion of the kidney, especially of the renal epithelium. L. W. RIGGS

Desensitizing action of rabbit serum after intraperitoneal injection of vital colors. J. MOLDOVAN AND M. ZOLOG. *Compt. rend. soc. biol.* 98, 1085-6(1928). Site of origin of the desensitizing substance after the injection of India ink in the sheep. J. MOLDOVAN AND T. TURCU. *Ibid* 1087-8. L. W. RIGGS

Nature of the desensitizing substance of the serum of animals blocked with India ink. J. MOLDOVAN, T. SLAVOACA AND M. ZOLOG. *Compt. rend. soc. biol.* 98, 1619-20(1928).—The substance in question is sol. in alc., is stable in acid soln., and resists the action of heat at 100° . L. W. RIGGS

The sensitizing principle of the aqueous or alcoholic extract of the node of Tawara (sheep and cattle). MARCELINÉ HOEBAERS. *Compt. rend. soc. biol.* 98, 1242-4(1928). L. W. RIGGS

Preparation of precipitating serums starting with proteins coagulated by heat. E. NICOLAS AND K. KATRANJEFF. *Compt. rend. soc. biol.* 98, 1310-1(1928).—Lab. details are given. Zoölogical and chemical specificity of precipitating serums obtained by means of raw proteins and of proteins coagulated by heat. *Ibid* 1312-4.—Cf. following abstr. L. W. RIGGS

Antigenic character of albumins modified by heat and their specific differentiation by precipitating serums. E. NICOLAS AND K. KATRANJEFF. *Centr. Bakt.* 98, 259(1926). L. W. RIGGS

Variations of urinary acidity in patients with pulmonary tuberculosis. R. GIEFFON AND R. BLASKO. *Compt. rend. soc. biol.* 98, 1393(1928); cf. *C. A.* 22, 2083.—The p_H , total acidity, org. acids and phosphates of 4 patients were detd. on 3 successive days. The variations in these constituents were large and cannot be explained by differences of diet, but probably are caused by crises of fatigue, dyspnea or tachycardia which accompany the disease. Loss in bases by urines of patients with pulmonary tuberculosis. *Ibid* 1394-5. L. W. RIGGS

Influence of aging on serums submitted to the Vernes reaction with resorcinol. A. BRETON. *Compt. rend. soc. biol.* 98, 1429-31(1928); cf. *C. A.* 22, 821.—The flocculating power of 44 serums on standing varied from day to day. These variations are indicated in general by a fall in the optic index in 90% of the samples. The variations are not proportional to the time of aging nor do they seem to follow any known law. L. W. R.

Acid-base equilibrium in spontaneous animal rickets. F. LIÉGEAIS. *Compt. rend. soc. biol.* 98, 1445-7(1928); cf. *C. A.* 21, 1485, 2031.—In the rachitic animals studied, regardless of species, there was a fall in the alk. reserve, a p_H at the inferior limit of normal values and a ratio $H_2CO_3/NaHCO_3$ above $1/10$. Spontaneous rickets in the dog, pig and colt, before any treatment, is a disturbance of the acid-base equil. in the sense of a generally compensated non-gaseous acidosis. Acid-base equilibrium and treatment of rickets. *Ibid* 1448-50.—Treatment of rickets in the dog by cod-liver oil was accompanied by a change in the blood p_H from 7.38 to 7.43, a rise of 10 to 15% in the total CO_2 and a corresponding rise in the $NaHCO_3$. The $H_2CO_3/NaHCO_3$ ratio changed from $1/10$ to $1/21.2$ and the Ca ions in mg. per l. fell from 33 to 27. The administration of "vigantol" (irradiated ergosterol Merck) to 2 normal dogs was without action on the mechanism of acid-base equil. L. W. RIGGS

Hyperglucemia in cardiac affections. I. GAVRILA AND E. CABA. *Compt. rend. soc. biol.* 98, 1466-8(1928).—In diseases attended with cardiac affections there are important disturbances of the gluco-regulating mechanism, which are more evident as the cardiac insufficiency is more pronounced. It is believed that insufficient liver functioning has an important influence in these cases. L. W. RIGGS

Cholesterolytic power of human serum in ocular affections. D. MICHAEL AND P. VANCEA. *Compt. rend. soc. biol.* 98, 1470-1(1928).—The conclusions of this study are not in agreement with those of Loeper *et al.* (cf. *C. A.* 22, 1374). L. W. RIGGS

Blood calcium and phosphorus after sympathectomy in hemiplegia. C. I. URECHIA AND G. POPOVICIU. *Compt. rend. soc. biol.* 98, 1486-8(1928).—In 6 cases of hemiplegia with contraction the Ca was greater on the side affected than on the normal side. The P varied within very narrow limits. In flaccid hemiplegia the Ca was diminished. In flaccid hemiplegia in which the sympathetic was paralyzed the Ca was diminished, but in the form with contractions in which the sympathetic was excited the Ca was increased. The state of the sympathetic appeared to have no influence on the P content. In 3 cases of sympathectomy Ca was diminished on the side of operation. The injection of ergotamine had no influence on the Ca content on the side already paralyzed. Tests with 2 sympathectomized dogs showed a diminution of Ca on the side of operation. The P was but slightly disturbed. L. W. RIGGS

The Widal agglutination reaction in healthy persons. A. N. BOSE AND S. K. GHOSH DASTIDAR. *Indian Med. Gaz.* 63, 320-1(1928).—Healthy persons of the middle class in Bihar do not as a rule show any agglutinins of the typho-coli group. The few individuals who do show their presence live under poor hygienic conditions. There is a remarkable absence of *B. dysenteriae* (Shiga and Flexner) agglutinins in all. The comparative immunity to the typho-coli organisms in persons living in tropical countries may be due to some protective factors in the serum other than agglutinins. L. W. R.

Practical suggestions regarding biochemical diagnostic methods. VICTOR C. MYERS. *J. Am. Med. Assoc.* 91, 167-73(1928).—The modern technics of testing body fluids are reviewed. The relations of the results of chem. analysis of body fluids in various pathol. conditions are discussed. L. W. RIGGS

Immune-body production of animals fed with lipoids. L. SURÁNYI. *Magyar Orvosi Arch.* 29, 222-30(1928); cf. *C. A.* 21, 2505.—Immunization expts. with typhoid, paratyphoid, dysentery, colon, bacilli and erythrocytes of sheep or rabbits fed cholesterol or lecithin showed that cholesterol-fed animals gave an immune serum with a very high titer, while the lecithin-fed animals gave a serum with a lower titer than that of controls. Animals which had been fed cholesterol for long periods received an acute fatal anaphylactic shock by the intravenous or intracardial application of heterogeneous protein such as typhoid bacilli or horse serum. The immune body is produced in the reticulo-endothelial cells. These processes are under the influence of the lipoids which modify the production of the immune body. L. W. RIGGS

Relation of complemental activity and of antibody production to the acid-base equilibrium. ISTVAN WEISS, ISTVAN SUMEGI AND Z. BENKOVICS. *Magyar Orvosi Arch.* 29, 239-43(1928).—The activity of the complement of guinea-pig serums is lowered either by changing the metabolism toward the acid or toward the alk. direction. The max. amt. of complement was formed when the p_H was normal. The hemolysin production of the acidified rabbits at the end of 7 days was about 2.5 times larger than in normal or alkalinized animals. The difference is smaller with the time and disappears during the third week. There is no significant difference between alkalinized and normal animals in hemolysin production. L. W. RIGGS

Influence of hemorrhage upon the adrenaline (Folin) content of the suprarenals of the rabbit. HIROSHI TACHI. *Tohoku J. Exptl. Med.* 10, 409-19(1928).—Bleeding causes a reduction in the adrenaline load, as detd. by the colorimetric test of Folin, Cannon and Denis, in the suprarenal glands of rabbits. Denervation of the glands prevents the depletion of the adrenaline content. L. W. RIGGS

Simplified apparatus and technic for the determination of the icterus index. RUSSELL C. PIGFORD. *J. Lab. Clin. Med.* 13, 658-9(1928).—An inexpensive equipment easily made in any lab. is described. Detn. are rapidly made on only 1 to 1.5 cc. of serum. Calcns. for diln. are seldom necessary. ETHEL W. WICKWIRE

The technic and interpretation of the van den Bergh test; its value in detecting latent jaundice. E. ELSWORTH STEEN. *Irish J. Med. Sci.* [6], 22, 625-33(1927).—In performing the "indirect" reaction the same technic is used as is followed in the "direct" reaction (cf. *C. A.* 21, 3921), except that 0.5 cc. of 95% EtOH is added to obtain the proper diln. in performing the quant. test. S. describes a positive "indirect" reaction as one which gives almost at once a pure violet color, unless "hepatic bilirubin" is present in the serum, when the color is first pink or red, growing to become more violet. The reaction will detect 1 pt. of bilirubin in 1,000,000 parts of serum. No substances found in serum interfere and lead to a false positive. Lutein obtained while on a certain diet gives an icteric appearance to the skin but not a positive van den Bergh reaction. "The great value of the test lies in the fact that it can demonstrate hyperbilirubinemia at a time when it cannot be detected by any other means." R. C. WILLSON

The calcium and phosphorus content of the blood in fractures. G. V. RUDD.

Med. J. Australia 2, 398-401(1927).—No significance is attached to the small irregular variations in the Ca and total P. R. suggests that the observed fall and subsequent rise in the inorg. P after fracture has occurred, may bear some relationship to the 2 phases of union, callus formation and active calcification. R. C. WILLSON

H—PHARMACOLOGY

A. N. RICHARDS

Influence of pituitrin on diuresis variously induced. F. P. KNOWLTON, A. N. CURTIS AND A. C. SILVERMAN. *Proc. Soc. Exptl. Biol. Med.* 24, 865-9(1927).—When diuresis is induced in anesthetized rabbits by the method of continuous intravenous injection, pituitrin acts to augment such diuresis. The effects are similar with various diuretics and with varying dosage and administration of the pituitrin. C. V. B.

Cardiac output as influenced by ephedrine, homocamfin, quinidine, quinine, chloral and chloroform. C. REYNOLDS AND S. N. BLACKBERG. *Proc. Soc. Exptl. Biol. Med.* 24, 870-1(1927).—Cardiac output, blood pressure, heart rate and O_2 consumption were detd. in dogs under the influence of these various drugs. C. V. B.

Action of narcotics on the ameba by means of microinjection and immersion. S. HILLER. *Proc. Soc. Exptl. Biol. Med.* 24, 938-9(1927).—The results of comparative studies on the influence of the narcotics ethyl alc., chlorotone, ether and $CHCl_3$ on the protoplasm of *Amoeba dubia* are described. C. V. B.

Action of ethyl alcohol on the intestine of mammals. E. MILANESI. *Arch. sci. biol. (Italy)* 11, 55-62(1928).—The effect of EtOH on the intestine (isolated) of dog was studied as the effects of reagents on this are known. A piece of intestine 5 cm long was immersed in Ringer-Locke soln. at 38° and EtOH added. Concns below 1:200 have no effect; increase to 1:1000 lowers the tone; and further increase reduces the involuntary movements. Addition of pilocarpine restores these movements even with concns. up to 1:200 of EtOH, while above this, $BaCl_2$ is necessary to restore the movements. Adrenaline further depresses the movements, stopping the involuntary entirely. The action of EtOH must be one of paralysis, since it is neutralized by pilocarpine, which is stimulating, and enhanced by adrenaline, which is depressing. A. W. C.

The protein sugar of blood. IV. Action of adrenaline and insulin on protein sugars of blood in normal dogs and with pancreas removed. G. QUAGLIARIELLO. *Boll. soc. ital. biol. sper.* 2, 890-2(1927); cf. *C. A.* 21, 3075.—Q has studied the effect of both insulin and adrenaline injections of normal dogs, and those with exptl diabetes by pancreas removal. Neither reagent affects the amount of protein sugars in the blood plasma noticeably, and while insulin does reduce the free sugars, it does not affect the protein sugars appreciably. A. W. CONTIERI

Camphor treatment of the late stages of pulmonary tuberculosis with hexetone. RICHARD MICHEL. *Beitr. klin. Tuberk.* 67, 577-81(1927).—Hexetone possessed the advantage over camphorated oil in being purer without danger of local irritation and of more rapid action. It is given in 1% soln. at daily, bi-daily and tri-daily intervals to a total of 50 injections. Beneficial results were obtained in severe bilateral conditions in pulmonary tuberculosis, especially with concomitant circulatory disturbances, such as diminished blood pressures or increased pulse frequency. H. J. CORPER

Insulin treatment in initial and stationary pulmonary tuberculosis. H. GROSSFELD. *Z. Tuberk.* 47, 389-93(1927).—Insulin fattening treatments are considered suitable for stationary, fibroid cases of tuberculosis. Focal reactions are not to be feared. Aside from the action upon the carbohydrate metabolism there are indications that the insulin can also favorably affect the tuberculosis. In the blood it causes a leucocytosis and counteracts increased pressure resulting from adrenaline. The tissue reaction is shifted to the alkaline side and chronic inflammation favorably affected. Increased carbohydrate combustion aids in detoxication of the tuberculosis products of disintegration. Insulin can be designated a histotropic hormone since it enables cells to utilize carbohydrates while in its absence the tissues lose their resistance to various infections. H. J. CORPER

Metal salt therapy. Sterilization of the infected organism (tetanus and tuberculosis). L. E. WALBUM. *Z. Tuberk.* 48, 193-216(1927); cf. *C. A.* 21, 963.—In various earlier reports it was pointed out that suitable minimal injections of metal salts protected rats against infection with virulent "Rattenbacillen" and guinea pigs against infection with mildly virulent tubercle bacilli. In the present report it is pointed out that a "Therapia sterilizans" toward virulent tetanus spores in mice can be attained by means of small quantities of Mn salts in an indirect manner. While mice with a latent tetanus spore infection can be activated by a subsequent staphylococcus inocu-

lation, the same animals remain healthy after treatment with suitable amts. of Mn. The organs of these mice planted on media after 1 injection revealed the spores still alive, but one injection would inhibit the development of tetanus following the injection of staphylococci. Like inhibitory results attained in guinea pigs infected with a mildly virulent strain of tubercle bacilli and treated with suitable doses of salts (usually the chloride) of W, Pt, Er, Ba, Al, La, Ce, Se, Cd, Mo and Ru. Like results attained in rabbits infected with a highly virulent strain of bovine tubercle bacilli (Bang) and treated with Cd, Mn, La and Ce. The organs were tested by guinea-pig inoculation. Large doses of metal salts are believed to depress the protective mechanism and cause a more rapid fatal outcome. The theoretic basis of chemotherapy according to Ehrlich (direct and sp. effect on the causative organism) so far as it concerns bacterial diseases is considered incorrect. Rather it should be aimed to stimulate the sterilizing energy of the organism.

H. J. CORPER

Acurogen therapy as a means of diminishing metabolism in pulmonary tuberculosis. G. PANEL. *Z. Tuberk.* **48**, 301-8(1927).—Reasoning that cases of pulmonary tuberculosis all have an increased metabolism, and in addn. diseases with increased basal metabolism exert an unfavorable influence upon the former, therapy should aim to oppose this by causing a diminution of metabolism. Jacobson's "Acurogen" prepd. from thymus, lymph gland tissues and heart tissues, combined with Fe, tannin, and allyl sulfide was used in 41 cases of pulmonary tuberculosis with the result that of 30 open cases 8 became free from bacilli and in 13 they were diminished in the sputum. Improvement resulted in 86% of the cases. The results are believed due to a diminished metabolism occasioned by the Acurogen therapy.

H. J. CORPER

The old and modern cinnamic acid treatment of pulmonary tuberculosis. T. STERNBERG. *Z. Tuberk.* **48**, 309-12(1927).—Landerer's favorable results in animal expts. were dependent on 2 properties of cinnamic acid, causing a generalized leucocytosis and provoking an aseptic inflammation at the tuberculous focus. The more favorable results in man are due to immunobiologic relations developed. Experiences with Elbon-Ciba (cinnamoyl-*p*-hydroxyphenylurea), which after resorption and addition of water, splits into cinnamic acid and hydroxyphenyl urea, are recorded. While Landerer aimed at a non-sp. irritation by massive administration, S. uses protracted administration resulting in continual benzoylizing of the blood and tissues. The sputum was favorably influenced qualitatively and quantitatively, the temp. dropped without perspiration or other concomitant symptoms indicating a lack of parallelism with the usual antipyretics, following this treatment. The diminution of bacilli with prolonged treatment is attributed to the favorable influence upon the secretions. Suited for this treatment are all cases with prolonged pyrexia, exclusive of septic temps. and outspoken exudative forms, as well as afebrile cases with profuse secretion and large amts. of bacilli. Initially 4 to 5 g. are given daily and brought to a max. of 8 g. After the disappearance of symptoms 2 g. as a daily dose are continued for 4 to 6 weeks.

H. J. CORPER

Metal salt therapy ad modum Walbum. Experiences with the manganese treatment of pulmonary tuberculosis. O. HELMS AND J. FREDERIKSEN. *Z. Tuberk.* **49**, 18-26(1927).

H. J. CORPER

The influence of chloroform narcosis on the blood lipase. F. KESSEL. *Zhurnal exptl. Biol. Med.* **1926**, 52-70; *Chem. Zentr.* **1926**, II, 3100.—In CHCl_3 narcosis, the lipase content of the blood increases until it reaches a max. after 8 hrs., and then becomes normal again after 21 hrs.

C. C. DAVIS

Influence of lobeline on the respiratory center paralyzed by certain poisons. A. TESIKOV. *Zhurnal exptl. Biol. Med.* **1926**, 159-68; *Chem. Zentr.* **1926**, II, 3101.—A discussion of the effect of lobeline on dogs whose respiration is impaired by morphine, heroine and CHCl_3 .

C. C. DAVIS

Pharmacological investigations on a mercury colloid. ERCOLE UGOLOTTI. *Arch. farmacol. sper.* **44**, 145-68(1928).—A colloidal prepn. of HgS , made by heating HgCl_2 with NaOH and egg albumin, was administered subcutaneously, intramuscularly, intraperitoneally and intravenously to guinea pigs, rabbits and dogs. With subcutaneous injection the portion contg. the finer and more stable micellae is absorbed, while the coarser and less stable micellae pass into the granular state and are deposited in the tissue near the site of injection. Within 3 or 4 days toxic symptoms develop, such as degeneration and necrosis of the renal and hepatic epithelia, accompanied by loss in body wt. and eventually resulting in death. This cannot be attributed to the ultimate absorption of the granular deposits which is extremely slow, but is due to the colloid initially absorbed. Intramuscular administration produces the same phenomena. When injected intraperitoneally, some of the unabsorbed granules appear in the lymph

phatic system, probably transported thither by the macrophages. Intravenously, the colloid is rapidly brought into the general circulation without forming a granular deposit either at the site of injection or elsewhere. The toxic effects on the system are the same as those produced by the ordinary mercurial preps. There is loss in wt., hepatic lesions with degeneration of the cells, acute nephritis and hyperplasia of the spleen. The antiseptic action associated with Hg ions is wanting. A. W. DOX

The reticulo-endothelial system and resistance to inorganic chemical poisons. G. VACCA. *Arch. farmacol. sper.* **44**, 177-92(1928).—A study of the increased resistance to Pb poisoning after injections of trypan red, trypan blue, pyrrole blue and collargol. A. W. DOX

Experimental investigations on the lack of habituation to morphine and synergized preparations of opium. VITTORIO SUSANNA. *Arch. farmacol. sper.* **45**, 33-43(1928); cf. *C. A.* **21**, 1679.—Dogs receiving repeated doses of morphine or opium preps. develop a tolerance to these narcotics. If, however, hyoscyamine or scopolamine is administered simultaneously with the morphine or opium, no tolerance is established. The narcosis produced by morphine is less intense than that produced by the opium preps., "pantopon," "narcopon," "pantergon," of which "pantergon" is the most potent. The toxicity of morphine and of opium preps. is increased more by hyoscyamine than by scopolamine. A. W. DOX

Action of adrenaline on the isolated heart. MARIO CHIO. *Arch. farmacol. sper.* **45**, 44-8(1928).—The frog heart was isolated and left *in situ* with a glass canula penetrating into the ventricle through the abdominal cavity, the veins being ligated in such a way as to avoid injury to the chest. Ringer soln. was perfused continuously at a diastolic pressure of about 5 cm. H₂O and systolic pressure of about 13 cm. H₂O. Under the influence of adrenaline in concns. of 1:100,000 to 1:10,000,000 the same variations in the work of the heart resulted as were obtained by very light circular compressions on the chest and on the auricles. A. W. DOX

Intoxication by hydrofluosilicic acid. J. DROST. *Pharm. Zentralhalle* **69**, 385 G (1928).—A fatal case of poisoning by drinking a soln. of com. hydrofluosilicic acid. W. O. E.

Action of guanidine on dehydrogenation in muscle. L. CALIFANO AND M. D'ALISE. *Riv. patol. sper.* **2**, 288-93(1927); *Physiol. Abstracts* **12**, 546.—Guanidine increases the oxidative activity of toad's muscle. H. G.

The chloride, base and nitrogen content of gastric juice after histamine stimulation. W. S. POLLAND, A. M. ROBERTS AND A. L. BLOOMFIELD. Stanford Univ. *J. Clin. Investigation* **5**, 611-37(1928).—The vol. of gastric secretion and the concn. of Cl⁻, base and N before and after histamine stimulation were detd. The titratable acid is increased by histamine. ARTHUR GROELMAN

Calcium therapy in diseases of children. PAUL LUTTINGER. *Arch. Pediatrics* **45**, 341-56(1928).—Review with full bibliography. Sections are devoted to Ca assimilation, dentition, rickets, tetany, tuberculosis, other therapeutic applications, administration of Ca salts, Ca synergists. JOSEPH S. HEPBURN

Review of the pathogenesis of ipecac and its alkaloids. T. H. MCGAVACK. *J. Am. Inst. Homeopathy* **21**, 300 G(1928).—Review of their pharmacol. action and therapeutic use with bibliography. JOSEPH S. HEPBURN

Pharmacology of the homeopathic drugs. L. J. BOYD. *J. Am. Inst. Homeopathy* **21**, 312-23(1928); cf. *C. A.* **22**, 988, 1398.—This paper is devoted to P, HgCl₂, gelsemium, hepar sulfur, hydrastis, ignatia, ipecac, iris, kalmia, ledum, lycopodium and podophyllum. JOSEPH S. HEPBURN

Influence of adrenaline on the excretion of acetone in different pathological conditions. SIGMUND HIRSCHHORN AND LEO POLLAK. *Z. klin. Med.* **105**, 371-402(1927).—Excretion of acetone bodies by a non-diabetic person, either spontaneously or as the result of withdrawal of carbohydrate, is markedly increased by subcutaneous injection of 1 mg. of adrenaline. The increase is apparent within the first hr. and usually does not last more than 4 hrs. It apparently extends to acetone, acetoacetic acid and β -hydroxybutyric acid. This effect of adrenaline is hindered by administration of carbohydrates. Adrenaline can produce an increase in ketonuria, in spite of the carbohydrate, only in cases which exhibit an especial tendency toward acetoneuria. Adrenaline gives rise to an especially marked increase in ketonuria in pregnancy, acute infectious processes, and some cases of bronchial asthma; in all of these states, the tendency toward ketonuria is increased by other conditions, e. g., withdrawal of carbohydrates. Likewise, in the acetoneuria of starvation, the chief factor is not the abs. glycogen-reserve of the liver, but the velocity with which the glycogen is used; for on this depends the velocity of the mobilization and utilization of the fat. In diabetic patients, adrena-

line causes only a very slight increase in the excretion of acetone when the blood sugar rises to very high values; however, the increase may occur later and last longer in such patients, than in non-diabetic individuals.

JOSEPH S. HEPBURN

Action of thyroid substance on the composition of the blood. FRITZ ROTHSCHILD AND MAX JACOBSON. *Z. klin. Med.* 105, 403-5(1927).—A thyreotoxic condition was produced by administration of thyroid substance (0.3-1.0 g. thyreophorin). The blood sugar exhibited a slight tendency to decrease but the av. of the expts. gave a normal value (120 mg.). The cholesterol increased in 9 expts., decreased in 1, and remained const. in 1 expt.; the max. increase was 20% of its initial value; the av. increase was from 209 (initial) to 233 (final) mg.; this was accompanied by a low-grade lipemia. The inorg. P_2O_5 showed a slight av. decrease from 6.8 to 6.6 mg., the org. P_2O_5 a decrease from 16.6 to 15.1 mg. The Ca frequently increased definitely; the K either decreased or remained const. The residual N was definitely decreased in 10 expts., the av. decrease being from 23.9 to 21.88 mg. per 100 cc. These changes were, on the whole, due to action on the sympathetic.

JOSEPH S. HEPBURN

Action of ergotamine (Stoll) on the composition of the blood in Basedow's disease and in animals. FRITZ ROTHSCHILD AND MAX JACOBSON. *Z. klin. Med.* 105, 406-9 (1927).—In 7 patients with characteristic symptoms of Basedow's disease, injection of 0.5 mg. of ergotamine tartrate had produced the following av. changes in the chem. compn. of the blood by the time the max. decrease in the pulse had been attained, usually 20 to 30 min. after the injection. Dextrose decreased from 170 to 142 mg. per 100 cc. Cholesterol decreased from 171.0 to 166.0; inorg. P_2O_5 decreased from 8.5 to 7.0; org. P_2O_5 decreased from 15.7 to 15.1; Ca decreased from 10.6 to 9.8; K increased from 17.5 to 19.1; residual N increased from 27.08 to 31.54. These changes were due chiefly to action on the vagus. In 6 expts. on animals, the av. changes produced were: Dextrose increased from 86 to 94; cholesterol decreased from 138 to 132; inorg. P_2O_5 increased from 8.8 to 9.3; org. P_2O_5 increased from 19.8 to 21.6; Ca increased from 10.9 to 11.1; K decreased from 21.78 to 21.59; residual N increased from 28.22 to 28.48. These changes were due chiefly to action on the sympathetic.

JOSEPH S. HEPBURN

Action of adrenaline on the composition of the blood. MAX JACOBSON AND FRITZ ROTHSCHILD. *Z. klin. Med.* 105, 410-3(1927).—Both patients and dogs were given 1 mg. of adrenaline subcutaneously, and blood was taken 30 min. later. The following changes (mg. per 100 cc.) occurred in the av. chem. compn. of the blood. Dextrose increased from 121 to 175; Ca increased from 9.0 to 10.7; K decreased from 19.2 to 18.4; cholesterol increased from 133.2 to 146.4; inorg. P_2O_5 decreased from 6.9 to 5.6; org. P_2O_5 decreased from 15.8 to 14.7.

JOSEPH S. HEPBURN

Action of atropine (bellafolin) on the composition of the blood. MAX JACOBSON AND FRITZ ROTHSCHILD. *Z. klin. Med.* 105, 414-6(1927).—Subcutaneous administration of an av. dose of 1 mg. of bellafolin caused the following changes (in mg. per 100 cc.) in the chem. compn. of the blood 30 min. later. Dextrose increased from 132 to 143; cholesterol decreased from 162 to 154; inorg. P_2O_5 increased from 4.83 to 5.8; org. P_2O_5 decreased from 15.03 to 13.6.

JOSEPH S. HEPBURN

Action of choline on the composition of the blood. MAX JACOBSON AND FRITZ ROTHSCHILD. *Z. klin. Med.* 105, 417-9(1927).—Choline chloride (10 cc. of 6% soln.) was injected intramuscularly into patients, and blood was taken 30 to 40 min. later. The action of choline on the vagus was shown by decreases in the dextrose (from 108 to 100 mg. on the av.), inorg. P, and cholesterol, and an increase in the org. P of the blood.

JOSEPH S. HEPBURN

The effect of methylene blue injections on the body temperature of the rat. A. D. STAMMERS. *Brit. J. Exptl. Path.* 7, 44-6(1926).

E. H.

The combined effect of phlorhizin and insulin upon water and carbohydrate metabolism. F. HIRSCH AND O. KLEIN. *Deut. Arch. klin. Med.* 155, 163-76(1927).—The simultaneous action of phlorhizin and insulin produces a larger diuresis than does phlorhizin alone; the effect is made still more pronounced by the ingestion of carbohydrates. Phlorhizin frequently increases the amt. of water and of NaCl in the blood, even though large quantities of water are not taken after the injection of the phlorhizin. The administration of large quantities of water after the injection of phlorhizin causes the blood glucose to fall rapidly to subnormal values, while the glucosuria is increased. If the water is accompanied by considerable carbohydrate, an initial rise in blood sugar is followed by a fall to subnormal values. Phlorhizin in company with insulin weakens the tendency of the latter to decrease the concn. of blood glucose; but in many cases more sugar was excreted than when phlorhizin was used alone.

P. Y. JACKSON

The utilization of salabrose in the animal organism. KARL BOYTINCK. *Deut. Arch. klin. Med.* 156, 72-9(1927).—Salabrose, a tetraglucosan, was administered by

mouth, and, as a 30% soln., intraperitoneally and subcutaneously, to dogs which for 5 days had been kept on a carbohydrate-free diet. After a total of 30-50 g. had been given by mouth, the urine and a hot-water ext. of the feces for 4 days were boiled with HCl and tested for glucose. No trace of glucose was found. When 50 g. salabrose had been given on 4 successive days, diarrhea set in, and glucose was found in the feces; none was found in the urine, however, during ten days. After the intraperitoneal or subcutaneous injection of 20 g. salabrose, no glucose could be detected in the urine. These results conflict with the observation of Deuel, Wadell and Mandell that salabrose is not absorbed by the organism. P. Y. JACKSON

The treatment of irregular heart action with quinidine. GOTTFRIED EISMAYER. *Deut. Arch. klin. Med.* **156**, 182-99(1927).—The use of quinidine is attended, in 10-20% of the cases studied, with dizziness, vomiting, or even with loss of consciousness and heart failure; and in cases of severe decompensation, with sudden death. On the other hand, regular heart rhythm was completely restored in 25% of the cases treated, and the regularity was found to persist sometimes for years; most of these patients were able to resume their usual work. A preliminary dose of 0.2 g. was given to test the ability of the patient to take the treatment, and then 0.4 g. 3 times daily. It is necessary when giving this treatment to keep the patient under observation for some time, as the undesirable complications may appear later. Should arrhythmia reappear the treatment may be repeated with good results. P. Y. JACKSON

Acid-base equilibrium and the osmotic resistance of the red corpuscles. ISTVAN WEISS AND ISTVAN SUMEGI. *Deut. Arch. klin. Med.* **159**, 147-51(1928).—There was introduced daily for 4 weeks into the stomach of 10 guinea pigs 6 cc. 0.2 N HCl, and into a sec. group 4 cc. 8% Na₂CO₃; a third control group was kept under the same external conditions as the first two. After 4 weeks the blood *p_H* values for the groups were, resp., 7.45, 7.58 and 7.70. The osmotic resistance of the red corpuscles to hypotonic NaCl soln. was detd. for each group, but the variations noted were all within the limits of exptl. error. The opinion is, therefore, not tenable that an increase in such osmotic resistance is due to erythrocytes newly formed by the acid stimulation of the marrow; or that variations in the acid-base equil. has an effect upon the osmotic resistance. P. Y. JACKSON

The treatment of acute and chronic rheumatic polyarthrits with pyramdone. RUDOLF BODENSTAB. *Deut. Arch. klin. Med.* **159**, 171-9(1928).—Clinical observations show the superiority of pyramdone over Na salicylate and aspirin. P. Y. JACKSON

The behavior toward adrenaline of the hexosephosphoric acids of the blood in the normal organism. HEINZ LAWACZECK. *Deut. Arch. klin. Med.* **159**, 257-66(1928).—The increase in the concn. of hexosephosphoric acids in debrinated blood *in vitro* is not influenced by the presence of adrenaline. The injection of adrenaline *in vivo* is followed by a marked decrease in the concn. of hexosephosphoric acids in normal and in various pathol. conditions. The decrease is followed by a secondary increase of about the same order of magnitude. The concn. of glucose increases after injection at such a rate that the max. concn. is reached at about the same time as the secondary max. for the hexosephosphoric acids. P. Y. JACKSON

The behavior toward insulin of the hexosephosphoric acids of the blood in the normal organism. HEINZ LAWACZECK. *Deut. Arch. klin. Med.* **159**, 267-74(1928).—The concn. of hexosephosphoric acids in the blood in normal or in various pathol. conditions is increased in 12-15 min. by the injection of 5-40 units of insulin from 11.3 to 16.9%. In a healthy dog the injection of 90 units of insulin produced in 15 min. an increase of 17.1%. The increase in concn. is followed by a secondary fall. Insulin *in vitro* was without effect upon the concn. of hexosephosphoric acids in the blood. P. Y. JACKSON

The effect of synthetic thyroxine upon persons with a normal thyroid. HANNS BAUR AND GUSTAV LOEWI. *Deut. Arch. klin. Med.* **159**, 275-87(1928).—Clinical observations upon non thyroid pathological conditions and upon normal persons show that synthetic thyroxine administered *per os* or subcutaneously has the same effect as a 100-fold dose of dried thyroid. An injection of 2 mg. thyroxine increases the basal metabolic rate 10-30%, and the effect continues for 24-48 hrs. Repetition of the injection for several days produces no proportionally larger increase; but larger doses have a toxic effect upon the nervous system and heart. P. Y. JACKSON

The sorrel-poisoning theory of lamb mortality. C. S. M. HOPKINS AND D. A. GILL. *New Zealand J. Agr.* **36**, 153-5(1928).—Expts. were carried out to det. the effect of oxalates and sorrel on rabbits and lambs in order to test the theory that the commonly occurring mortality among fat lambs is caused by sorrel poisoning. Rabbits were easily killed by stomach doses of 40 grains of Na₂C₂O₄ in soln., or repeated intravenous

injections of solns. Stomach doses and intravenous injections of $\text{Na}_2\text{C}_2\text{O}_4$ were also fatal to lambs. Postmortem examn. of the kidneys of the lambs revealed an inflamed condition and the presence of oxalate crystals. Continuous feeding of an almost exclusive diet of sorrel for 4 weeks was not fatal to lambs but a few crystals of oxalate could be detected in postmortem examn. of the kidneys. Conclusion: Mortality among lambs cannot be due to sorrel poisoning. K. D. JACOB

Treatment of malaria with plasmochin and plasmochinum compositum. P. H. OLIVER AND A. A. HÜLSHOFF. *Geneeskund. Tijdschr. Nederland. Indie* 67, 907-21 (1927).—Plasmochin (I) is well tolerated. Slight cyanosis occurred only in a few cases. With the exception of a few relapses the blood in tertian and quartan malaria was sterilized within 4.4 days. The gametes of tropical malaria are resistant to quinine, the rings to I. The gametes disappeared under I after 6 days. Plasmochinum compositum (II) is recommended for tropical malaria. The rings and gametes disappeared within 4.4 days. Only in a few cases gametes previously absent appeared in the blood after 2 days of II. Quinine and I act like II. In order to prevent relapses the treatment ought to be continued for 21 days with 3 tablets of I or II daily. I is well tolerated by blackwater-fever patients sensitive to quinine. MARY JACOBSEN

Malaria therapy. SURBECK. *Geneeskund. Tijdschr. Nederland. Indie* 67, CXXXVI-CXLI (1927).—Quinine is rapidly eliminated. Its concn. in the blood is, therefore, proportional to the body wt., and the dose ought to be proportional to the latter. The following doses of quinine-HCl are to be given daily during the fever period and at least 4 days after defervescence: 1-1.5 g. for less than 50 kg. wt., 1.5-2 g. for 50-75 kg., 2-3 g. for over 75 kg. Where the absorption *per os* is unsatisfactory half the dose should be given subcutaneously. The alternate use of quinine and Na cacodylate or nearsphenamine after defervescence is highly recommended. In children a 5% sirup of FeI gives excellent results. Adrenaline given orally is a good adjuvant. The adrenaline test is of good prognostic value in splenomegaly. I as a 5% tincture or as an iodotannin, or a weak Lugol soln. given intravenously is an excellent adjuvant. The Ag salts of arspenamine and nearsphenamine have a greater gametocidal effect and are more stable in the tropics than these preps alone. A combination of Ag arspenamine and Lugol soln. given intravenously was used with good results. M. J.

Insulin and synthalin in diabetes of childhood. A. TONO. *Pediatria Rivista* 35, 1125 (1927).—When properly used insulin gives better results. MARY JACOBSEN

Novum Sofos in tuberculous eye affections of children. F. DURANTE. *Pediatria Rivista* 35, 1139 (1927).—In 2 cases of keratitis and 6 of kerato-conjunctivitis 2 injections every 2nd day brought about recovery without relapse. MARY JACOBSEN

Effect of tuberculin therapy on Pirquet's reaction and blood sedimentation velocity. MICHELE MIRAGLIA. *Pediatria Rivista* 35, 1145-52 (1927).—Cut-reaction and general condition are favorably influenced by tuberculin therapy; the sp. lesions and the sedimentation velocity are hardly affected. The latter is accordingly a more reliable index of the patient's condition than the cuti-reaction. MARY JACOBSEN

Ureides of bromovaleric acid. II. Influence of the branching of the chain on the physiological properties. R. FOURNEAU AND G. FLORENCE. *Bull. soc. chim.* 43, 111-6 (1928); cf. *C. A.* 22, 1329.—A study of the hypnotic action of the ureides of α -bromovaleric, α -bromoisovaleric, α -bromomethylethylacetic and bromopivalic acids.

The hypnotic intensity increases with the branching of the chain, the ureide of bromopivalic acid being more effective than the other three. LOUISE KELLEY

Use of Lugol's solution in exophthalmic goiter. JOSEPH L. DECOURCY. *Ann. Surgery* 86, 871-6 (1927).—The beneficial influence of Lugol's soln. is due to a rapid formation of colloid material in the I-famished gland, resulting in back pressure on the secreting cells and the thin-walled veins surrounding the acini. Hence, passive edema follows and the cells, rendered temporarily inactive, fail to absorb the toxic substance; consequently the patient's clinical condition improves. New blood vessels are formed and the older ones accommodate themselves to the changed conditions, so that absorption is resumed and clinical condition again becomes worse. FRANCES KRASNOW

The action of quinine on animal cells. MARIE FEILER. *Arch. Protistenk.* 61, 119-31 (1928); cf. *C. A.* 22, 1804.—Diln. of quinine to $10^{-7.5}$ exerts a stimulating effect on paramecium, bringing about an increase in its size and rapidity of division. A stimulating effect is also produced if the animal is placed in a fatal concn. (1/30,000) for a few min. and then placed in quinine-free water. The toxicity of quinine is much greater in light than in the dark. If placed first in arsenic soln., the animals are then more resistant to quinine. FRANCES KRASNOW

The action of plasmochin on *Paramecium caudatum*. MARIE FEILER. *Arch. Protistenk.* 61, 133-43 (1928).—This drug, a synthetic alkaloid of the quinoline group,

shows properties similar to those of quinine. The fatal action occurs in solns. more concd. than that for quinine. Plasmochin is more effective in the dark than is quinine.

FRANCES KRASNOW

Notes on the therapy for tropic ulcers. F. M. PETER. *Arch. Schiffs-Tropen Hyg.* 31, 447-59(1927).—The pyrogallol-zinc-powder therapy does not meet with success in long-standing cases. In 2 cases "Pyrogallol plaster" was given previous to pyrogallol zinc powder with remarkably good results.

FRANCES KRASNOW

The mechanism of the action of germanin (Bayer 205) on trypanosomes. SCH. MOSCHKOWSKI. *Arch. Schiffs-Tropen Hyg.* 31, 541-2(1927).—Guinea pigs experimentally infected with *Trypanosoma brucei* and *s. aurum*, when under treatment with Bayer 205, permit no increase in the no. of parasites. Treatment of the parasites for $\frac{1}{2}$ to $1\frac{1}{2}$ hrs. with a 1:22,000 soln. has no effect on its virulence; $\frac{1}{2}$ hr. in a concn. of 1:1000 lengthens the incubation period and $3\frac{1}{2}$ hrs. in this concn. obliterates its virulence. The *in vivo* dose is the same.

FRANCES KRASNOW

Action of *Ixodes ricinus* (Ixodidae) on human skin. E. N. PAVLOVSKII AND A. K. STEIN. *Arch. Schiffs-Tropen Hyg.* 31, 574-86(1927).—The saliva of *I. ricinus* cause a popular reaction on human skin. It is toxic, thermolabile and specific. Emulsions of the various organs call forth non-specific reactions.

FRANCES KRASNOW

Efficacy of "iodine vermicide" pills for the treatment of ascarid and hookworm infestations in silver foxes. Critical experiments. W. L. CHANDLER. *J. Am. Vet. Med. Assoc.* 71, 218-20(1927).—The drug was found to be very efficient.

F. K.

The physiology of glands. LEON ASHER. CX. **Humoral regulation of the heart beat with cholate.** S. MATSUYAMA. *Z. Biol.* 86, 495-502(1927); cf. *C. A.* 21, 3663. Cholate in concns. of 1:4000 and 1:6000 strengthens the heart beat (rats). The effect produced is greater than that of adrenaline. CXI. **Influence of cholate on pharmacological intestinal remedies.** *Ibid* 516-22.—After inhibition of intestinal movement by atropine, cholate administration effects good movement. The stimulating action of pilocarpine is enhanced by cholate. Adrenaline does not produce inhibition of motion if cholate is administered previously.

FRANCES KRASNOW

The toxicity and trypanocidal action of antimony compounds with 3- and 5-valent antimony (according to investigations with Antimosan). GEORGE BOCK. ROBERT KOCH Inst. *Z. Hyg. Infektionskrankh.* 107, 396-406(1927). Antimosan is more toxic for white mice and rats when given subcutaneously than when given intraperitoneally. The addn. of colloids hindering absorption, such as gum arabic, gelatin and agar, on intraperitoneal injection, brings the toxicity up to that found for subcutaneous injection. Prevention of elimination by ligating the ureters in the rat does not lead to an increase in toxic action after subcutaneous injection, but greatly increases that after intraperitoneal injection. These results are probably explained on the basis of chem. changes in antimosan in the body. Expts. show that oxidation of antimosan to the 5-valent form detoxicates the compd. The oxidized, 5-valent antimosan is likewise much less trypanocidal.

E. R. LONG

Myrtillin. FREDERICK M. ALLEN. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 81, 462(1927).—Myrtillin is an ext. of green leaves prepd. by the method of R. I. Wagner. It is of unknown chem. nature. Its physiol. action is non-toxic, it reduces adrenalinic hyperglucemia, and accelerates O_2 consumption after carbohydrate ingestion in normal and diabetic subjects. It enables totally depancreatized dogs to heal wounds and to live 4 to 6 weeks. Myrtillin is not a substitute for insulin, but is probably an accessory substance which is widely distributed in nature and which plays a part in the carbohydrate metabolism of animals and plants.

J. P. LYMAN

Carbon dioxide as a narcotic agent. II. The effect of carbon dioxide upon the contraction of striated muscle of the frog. CHARLOTTE HAYWOOD. *Univ. of Penn. Am. J. Physiol.* 82, 241-9(1927); cf. *C. A.* 22, 463.—When small muscles of the frog were immersed in Ringer soln. satd. with CO_2 the contraction was reduced in 1 min. to 80% and in 5 min. to 25% of the original. The effects could not be imitated by lack of O_2 or by changing the acidity of the medium by adding a non-penetrating acid such as HCl. The addn. of $NaHCO_3$ did not abolish the typical effects of CO_2 but did diminish them. The narcotic action of CO_2 may be assocd. with its ability to produce intracellular acidity.

J. P. LYMAN

The physiological action of cholesterol. MARTIN F. CASHIN AND VLADIMIR MARAVSK. *Royal Victoria Hosp., Montreal. Am. J. Physiol.* 82, 204-8(1927).—The intravenous injection of emulsions of cholesterol in gelatin into rats proved to be toxic and to have a profound anesthetic action. The toxicity of cholesterol was modified and reduced by the simultaneous administration of lecithin. After the injection of cholesterol

the cholesterol content of the blood fell and there was an increase in the cholesterol of the lung tissue. J. F. LYMAN

The value of intravenous and intraperitoneal administration of oxygen. GEOFFREY BOURNE AND RALPH G. SMITH. Washington Univ., St. Louis. *Am. J. Physiol.* **82**, 328-34(1927).—The intravenous injection of O_2 , in amts. sufficient to supply the necessary O_2 , caused pulmonary embolism and heart failure. When pure O_2 was introduced intraperitoneally there was enough absorption in some cases to cause a diminution in an experimentally produced anoxemia. J. F. LYMAN

Histamine and salivary secretion. MARGARET E. MACKAY. Dalhousie Univ., Halifax, N. S. *Am. J. Physiol.* **82**, 546-56(1927).—Histamine seems to have a double action on the submaxillary gland: (1) a secretory effect, which is greatly increased by previous nerve stimulation, and (2) a mechanical effect due to pushing out saliva by action on the contractile elements in the gland. J. F. LYMAN

Insulin anhydremia. Importance of water reserve in a physiological crisis. DAVID L. DRABKIN AND H. SHILKRET. Yale Univ. *Am. J. Physiol.* **83**, 141-6(1927).—Dogs desiccated through water starvation when given large doses of insulin developed a more profound anhydremia than those which had water. Spastic convulsions were not observed in the desiccated animals although they appeared in those given fluids. The latter invariably recovered upon glucose administration, while those deprived of water for periods longer than 4 days did not survive. J. F. LYMAN

Absorption of insulin from the alimentary tract of depancreatized dogs, when protected by blood serum. JOHN R. MURLIN AND ESTELLE E. HAWLEY. Univ. of Rochester. *Am. J. Physiol.* **83**, 147-61(1927).—When insulin, mixed with blood serum (possessing antitryptic activity), was given by stomach tube to depancreatized dogs, insulin was absorbed into the blood and showed its usual physiol. effects such as increased respiratory quotient, disappearance of sugar from the urine and a fall in blood sugar. Four depancreatized dogs were kept alive for 41 to 125 days by the administration of insulin by stomach tube. J. F. LYMAN

The calorogenic action of adrenaline. S. SOSKIN. Univ. of Toronto. *Am. J. Physiol.* **83**, 162-70(1927).—Adrenaline caused a marked rise in O_2 consumption and an increase in the respiratory quotient of normal dogs. In liverless dogs adrenaline did not prevent the usual decline in O_2 intake, or show any significant influence on the respiratory quotient. In depancreatized dogs adrenaline caused a definite rise in the O_2 intake but no change in the respiratory quotient. The calorogenic action of adrenaline, therefore, is primarily on the liver, not on the direct stimulation of the tissue cells or on the pancreas. The high blood sugar, caused by adrenaline in the normal dog, is not the essential cause of the increased metabolism which follows its administration. J. F. LYMAN

Changes in the sedimentation rate of the erythrocytes and in the plasma proteins following prolonged chloroform administration to the dog. M. D. ROURKE AND E. D. PLASS. *Am. J. Physiol.* **84**, 42-7(1928).— $CHCl_3$ poisoning in dogs resulted in liver necrosis, a marked drop in plasma fibrinogen and a greatly reduced rate of cell sedimentation. The rate of sedimentation of the red blood cells is thought to depend upon the plasma fibrinogen. J. F. LYMAN

The distribution of arsenic in the tissues after serial administration of neoarsphenamine. F. P. UNDERHILL AND ALICE DIMICK. *Am. J. Physiol.* **84**, 56-60(1928).—After administering neoarsphenamine the distribution of As in the organs of dogs was in the following decreasing order: kidneys, spleen, liver, thyroids, adrenals, heart, muscle, reproductive organs and brains. J. F. LYMAN

The origin of the glucose in the hyperglucemia induced by pituitrin. G. A. CLARK. Sheffield Univ. *J. Physiol.* **64**, 324-30(1928).—The intravenous injection of pituitrin into decapitated, eviscerated cats increased the rate of disappearance of blood sugar. In cats under amylal anesthesia, with the liver out of the circulation, pituitrin did not produce hyperglucemia as in normal animals nor did it diminish the rate of fall of blood sugar. The source of glucose in pituitrin hyperglucemia, therefore, is the liver glycogen. J. F. LYMAN

The effect of atropine, ergotamine and pituitrin on phlorhizin glucosuria. A. B. ANDERSON AND M. D. ANDERSON. Cambridge. *J. Physiol.* **64**, 350-5(1928).—The administration of atropine and ergotamine had no effect on the glucose—nitrogen ratio in the urine of phlorhizinized rats. There is no evidence therefore, that phlorhizin produces glucosuria by acting on the sympathetic nerve endings of the kidney. Pituitrin had no demonstrable action on phlorhizin diabetes. J. F. LYMAN

The effect of the "heart tonics" and other drugs upon the heart tone and coronary circulation. RICHARD BODO. Univ. College, London. *J. Physiol.* **64**, 365-87(1928).—

When heart rate, venous inflow and arterial resistance are const. the tonic action of drugs was revealed in the heart-lung prepn. by a diminution in the diastolic and systolic vols. of the ventricles. Digitalis showed a delayed but lasting tonic effect; caffeine gave a rapid but evanescent tonic action; and after insulin a tonic effect could be noticeable only once in each prepn. Camphor, NaNO_2 , pituitrin and quinidine produced dilatation. Strychnine and amyl nitrite had no effect on heart tone. Digitalis, caffeine, camphor and nitrites increased the coronary flow; pituitrin, quinidine and insulin diminished it. J. F. LYMAN

The effects of subcutaneous and intraperitoneal injection of oxygen upon the oxygen saturation of the arterial blood. H. W. DAVIES AND M. RABINOVICH. *Proc. Physiol. Soc., J. Physiol.* **64**, xxxviii(1928).--The intraperitoneal or subcutaneous administration of O_2 to anoxemic dogs did not affect respiratory rate and caused little or no increase in O_2 satn. of the arterial blood J. F. LYMAN

The fixation of inorganic colloids in the organism by the application of local anesthetics. G. SPAGNOL. *Boll. soc. ital. biol. sper.* **2**, 768-9(1927); cf. *C. A.* **22**, 452. If an anesthetic is applied for 5-15 seconds on the skin of an animal and immediately afterwards an inorg. colloid is injected intravenously, the colloid becomes fixed in the cutaneous and subcutaneous tissues in the area where the anesthetic has acted. CHCl_3 , CCl_4 , $\text{C}_2\text{H}_5\text{Br}$ and Et_2O may be used as anesthetics although the latter is not as satisfactory as the others. Fixation is noticeable even with small doses of colloid: 0.01 g. of HgS or PbS per kg. rabbit. The same phenomenon is observed if FeSO_4 is injected. This becomes transformed by the organisms to $\text{Fe}(\text{OH})_3$ which is recognized by its rusty color. These results are not only of theoretical importance, but may have possible application in the therapeutics of skin diseases. PETER MASUCCI

The hyperglucemic action of certain protein disintegration products. CIACCIO AND TRIMARCHI. *Boll. soc. ital. biol. sper.* **2**, 780-3(1927). Witte's peptone was fractionated by each of the following methods: (1) addn. of 9 vols. abs. $\text{C}_2\text{H}_5\text{OH}$ to a coned peptone soln.; (2) extn. of the peptone with acid 60%, $\text{C}_2\text{H}_5\text{OH}$, addn. of NaOH to pH 5-6, filtration, concn. at reduced pressure at 30°, addn. of 9 vols. 96% $\text{C}_2\text{H}_5\text{OH}$, washing of the ppt. with $\text{C}_2\text{H}_5\text{OH}$ and ether and drying *in vacuo*; (3) treating the peptone according to the Doisy, Somogyi, Shaffer method. The ppt. from each of the three methods, the residue from the alc.-sol. portion, and the whole peptone itself were administered to starved rabbits in 0.5-10-mg. doses intraperitoneally and orally. A decided, const., lasting hyperglucemia was obtained from the ppts. of the 3 methods, 5-10-mg. doses raised the blood sugar 100%, 0.5-1.0 mg. doses raised it 30%. The alc.-sol. portion even in 10 mg. doses was inert. The oral administration of the ppt. from the second method in 1-3-mg. doses raised the blood sugar 70-100%. (4) The whole peptone administered in similar doses had no effect. PETER MASUCCI

The action of urotropine on the contraction of the uterus. C. VERCESI. *Boll. soc. ital. biol. sper.* **3**, 144-8(1928).--Clinical and exptl. results indicate that urotropine has a marked action on the contraction of the uterus. The intravenous injection of urotropine gives rise to contractions which occasionally expel the fetus, the action on the isolated uterus is variable but can be differentiated from that of the higher alkylamines. PETER MASUCCI

The action of indole on experimental teratoids. M. LAPIDARI. *Boll. soc. ital. biol. sper.* **3**, 214-5(1928).--Repeated injections of indole into white rats and chickens failed to produce any changes in the malignant tumors; neither did it influence the development and duration of these teratoids. PETER MASUCCI

Muscular contraction by certain alkaloids and phosphagen. G. MARTINO AND G. CARBONARO. *Boll. soc. ital. biol. sper.* **3**, 218-21(1928).--A few drops of a 1% caffeine and 1% quinine-HCl soln. were instilled into the isolated gastrocnemius and crural muscle of frogs. Inorg. phosphoric acid and phosphagen were detd. after 1-90 min. of exposure. The same detns. were made on the untreated homologous muscles. The results given in tabular form show a diminution in phosphagen and a corresponding increase in inorg. phosphoric acid. The variations in muscle phosphagen are similar to those obtained with heat, CHCl_3 and alc. PETER MASUCCI

Variations in the phosphagen content of striated muscles by the action of chloroform and certain alcohols. G. MARTINO. *Boll. soc. ital. biol. sper.* **3**, 225-9(1928).--Inorg. phosphoric acid and phosphagen were detd. in one of the gastrocnemius or crural muscles of the frog and the same detns. were made on the homologous muscles after exposure for various intervals to the vapors of CHCl_3 , MeOH , EtOH and AmOH . The tabulated results show that exposure to CHCl_3 vapors causes the complete disappearance of phosphagen and an increase of 54 to 112% inorg. phosphoric acid. With the alcs. the results were similar but not so marked; the

diminution in phosphagen was least with MeOH, more marked with EtOH and still more pronounced with AmOH.

PETER MASUCCI

The influence of diuretin on animals treated with corpus luteum extracts. G. RUGGERI. *Boll. soc. ital. biol. sper.* 3, 233-5(1928).—Diuretin was injected into female rabbits and the glucemic titer was detd. at one half hr. intervals up to 3 hrs. There was a decrease in blood sugar which became normal again after 3 hrs. The rabbits were then fed corpus luteum. Several days later diuretin was again injected and the blood sugar detd. There was an increase in blood sugar instead of a decrease as before.

PETER MASUCCI

The action of atropine and insulin on pilocarpine hyperglucemia. ANTONIETTA ORRU. *Boll. soc. ital. biol. sper.* 3, 242-7(1928).—The administration of pilocarpine to rabbits rendered hypoglucemic with small doses of insulin raises the blood sugar above the normal level; the increase is of short duration as hypoglucemia again follows. If large doses of insulin are given, pilocarpine in any amt. and administered at different periods fails to influence the hypoglucemia. Insulin convulsions are neither lessened nor relieved by pilocarpine.

PETER MASUCCI

The influence of soaps and certain anesthetics on the coagulation of the blood. PAOLA MAZZA. *Boll. soc. ital. biol. sper.* 3, 250-1(1928).—Ca oleate accelerates the coagulation of the blood and plasma. The addn. of anesthetics (1 drop) to 1 cc. salted plasma before diln. with H₂O hastens the coagulation of the dild. plasma. The order of coagulation is: CHCl₃, Et₂O, EtOH and CCl₃CHO.H₂O.

PETER MASUCCI

Studies on adrenaline-like substances. The influence of ephetonine on carbohydrate metabolism. L. CANNAVO. *Boll. soc. ital. biol. sper.* 3, 259-61(1928).—The action of ephetonine (phenylmethylaminopropanol hydrate) on carbohydrate metabolism is similar to that of adrenaline; its activity is less pronounced but it is effective orally and is less toxic than adrenaline.

PETER MASUCCI

The comparative pharmacological action of manganese chloride, carbonate and phosphate. I. SABBATANI. *Boll. soc. ital. biol. sper.* 3, 268-72(1928).—The lethal dose of MnCl₂, MnCO₃ and Mn₃(PO₄)₂ was detd by intravenous injection into rabbits. The M. L. D's were: MnCl₂ 0.00023-0.00039; MnCO₃ 0.00025-0.00039; Mn₃(PO₄)₂ 0.00030-0.00042 g.-mols per kg. wt.

PETER MASUCCI

The action of morphine on the pulmonary vessels. A. IUISADA. *Boll. soc. ital. biol. sper.* 3, 270-2(1928).—Small doses of morphine have no action on the pulmonary vessels. Large doses, 2 cg. per kg., increase the vol. of the lungs, caused a hypertension in the region of the pulmonary artery, in the venous part of the lung, and in the left auricle. The beneficial effect of morphine in pulmonary edema is due to some action outside the lungs.

PETER MASUCCI

The behavior of hepatic glycogen in rabbits treated with pilocarpine. ANTONIETTA ORRU. *Boll. soc. ital. biol. sper.* 3, 277-9(1928).—In the rabbit the injection of pilocarpine increases the velocity of transformation of hepatic glycogen into glucose which gives rise to hyperglucemia.

PETER MASUCCI

Modifications in the ureogenic function and protein metabolism following chloroform narcosis. G. MONTEMARTINI. *Boll. soc. ital. biol.* 3, 279-81(1928).—The total N and urea in the blood and urine, NH₃ N, amino acids, and uric acid in the urine of 16 patients under local anesthetic were detd. The azoturia coeff. decreased till the 5th day; Maillard's coeff. increased progressively and in proportion. The evidence shows the vulnerability of the liver under chloroform narcosis.

PETER MASUCCI

Studies on antagonism. Chloral and camphor. ALFONSO CHIODO. *Boll. soc. ital. biol. sper.* 3, 284-6(1928).—The combined action of chloral and camphor was studied on the heart of frog and toad. The antagonism between the 2 drugs was bilateral. For certain doses chloral exerted an antagonistic action to the neg. chronotropic and inotropic action of camphor. By varying the doses of chloral and camphor, the pharmacol. action also varied; in some cases there was antagonism, in some synergism, and in others simple addn.

PETER MASUCCI

Emetic action and the valence of antimony. SATULLO ROSARIO. *Boll. soc. ital. biol. sper.* 3, 287-9(1928).—The comparative emetic action of tartar emetic and oxidized Sb K tartrate was studied. Tartar emetic administered to dogs orally produces vomiting in doses of 0.05-0.10 g. With K Sb tartrate it is necessary to give 6 g. to produce vomiting. The addn. of an atom of O to tartar emetic, the oxidation of Sb⁺⁺⁺ to Sb⁺⁺⁺⁺ results in a product requiring a dose 100 times larger to obtain the same pharmacol. effect. The difference in the action of the 2 compds. is interpreted. The strong emetic action of tartar emetic is attributed to the formation in the stomach of SbOCl under the influence of HCl. The oxidized product does not give a ppt. of SbOCl with the same concn. of HCl.

PETER MASUCCI

Intermediate carbohydrate metabolism. V. Effect of amytal narcosis on the different types of reaction of the dog to prolonged intravenous injection of glucose. U. WIERZUCHOWSKI AND H. GADONESKA. *Biochem. Z.* **191**, 398-410(1927); cf. *C. A.* **22**, 1616.—Amytal narcosis itself has no effect on sugar metabolism, but it does seem to interfere seriously with the assimilation rate when glucose is being injected, this being reduced by 0.15 g. glucose per hr. and per kg. Insulin administered before the injection of glucose apparently has no effect. Although the amytal narcosis does reduce appreciably the rate of assimilation it has no influence on the special form of the sugar curve, so that the finer adjustments of the carbohydrate metabolism cannot be affected by the amytal narcosis, which leaves unaffected also the blood lactic acid. Amytal is very valuable for prolonged anesthesia but is contraindicated for bitches in late pregnancy.

S. MORCULIS

The effect of sympathetic and parasympathetic poisons on the content of creatine in the muscle. HIDEO AKATSUKA. *J. Biochem. (Japan)* **8**, 57-77(1927).—Formation of creatine from its mother substance is increased by the action of adrenaline and decreased by ergotoxine. Physostigmine accelerates the transformation of creatine into creatinine. The simultaneous action of adrenaline and cold stimulate the production of creatine from its mother substance, leading to a decrease of creatine after a certain time because of lack of mother substance. Curarized animals are not affected by these drugs, and the creatine-forming process diminishes with decreasing body temp. In homeothermic animals cooling to a tolerable degree causes oversecretion of adrenaline and is accompanied by an increased creatine content of muscle, the production of the latter being accelerated by the adrenaline. In poikilothermic animals, on the contrary, the cooling slows down the chem. processes in the organism and there is no appreciable influence of these drugs on the muscle creatine content.

S. MORCULIS

Experimental study of acquired resistance of the rabbit renal epithelium to uranyl nitrate. WARREN C. HUNTER. Univ. of Michigan. *Ann. Internal Med.* **1**, 747-89 (1928).— $\text{UO}_2(\text{NO}_3)_2$ produces in the rabbit a glomerulotubular nephritis which in the chronic stage resembles that seen in the human being, although the tubular changes are the more prominent. Repair begins early in the epithelium of the tufts and Bowman's membrane. Frequently the number of new cells is excessive, forming crescents or even obliteration of the capsular space, glomerular atrophy and hyaline degeneration. In some cases the capsular space is dilated and cystic with atrophy of the accompanying glomerulus. The regeneration of tubular epithelium is remarkable, particularly if the doses are so graduated that not all cells are killed at once. By gradually increasing the dose 54 to 96 times the amt. capable of producing demonstrable changes in the normal rabbit can be given without injury. The most probable explanation is that the regenerated cell is able to prevent the poison from uniting with the cell protein.

JOHN T. MYERS

A fatality following the intravenous use of ammonium α -iodoxybenzoate. BERNARD A. MANACE. Univ. of Michigan. *Ann. Internal Med.* **1**, 825-7(1928).—Death followed the administration of 100 cc. of 1% "Amidoxyl" apparently due to hypersusceptibility. The first dose to a patient should be small to rule out idiosyncrasy especially if there is known idiosyncrasy to salicylates, since the action of the two drugs seems similar. The subsequent doses should be increased with caution.

JOHN T. MYERS

The changes in serum bactericidins during narcosis and during surgical attack on animals. E. EICHHOFF AND W. PFANNENSTIEL. Univ. of Breslau. *Centr. Bakt. Parasitenk. I. Abt.* **106**, 31-41(1928).—Injections of morphine in rabbits strikingly increase the bactericidal action of the blood serum within 5 to 24 hrs. It is not a direct effect on the bacteria. Pure CHCl_3 anesthesia definitely increases the bactericidal power, but the effect of ether is less. Combined ether morphine anesthesia has no more effect than morphine alone. This mechanism may be concerned in post-operative complications.

JOHN T. MYERS

The influence of his profession on the erythropoietic function in the radiologist. J. W. MOLDAWSKY. Univ. of Berlin. *Folia Hematol.* **36**, 145-73(1928).—Röntgen rays and Ra first irritate the spleen, then cause hyperfunction, then fatigue followed by aplastic anemia. The mechanism is uncertain but may be the ozone or HNO_2 in the air.

JOHN T. MYERS

Blood changes occurring during the course of treatment of malignant disease by lead, with special reference to punctate basophils and the platelets. RONALD W. BROOKFIELD. Univ. of Liverpool. *J. Path. Bact.* **31**, 277-301(1928).—Intravenous injection of colloidal Pb for the treatment of malignant disease causes a considerable temporary anemia due to peripheral destruction of erythrocytes. The rapid return to normal is due to increased bone marrow activity. The stippled cells are closely re-

lated to reticulated cells and are probably young cells altered by a degenerative process. No change attributable to Pb was found in the white cells. Injections of a suspensoid of metallic Pb along with $\text{Pb}(\text{OH})_2$ and PbCO_3 caused an immediate rise in the number of circulating platelets, while a mixt. of colloidal Pb and Se caused an immediate fall. There is a long bibliography.

JOHN T. MYERS

The etiology of hepato-lenticular degeneration: experimental liver cirrhosis: poisoning with manganese, chloroform, phenylhydrazine, bile and guanidine. WESTON HURST AND PHYLLIS E. HURST. Miller General Hosp., London. *J. Path. Bact.* **31**, 303-42 (1928).— MnCl_2 given subcutaneously destroys the peripheral cells of the liver lobule and leads to extensive cirrhosis. Its effect is greatly enhanced by repeated intravenous injections of living *B. coli*. Phenylhydrazine affects the cells in the center of the lobule and does not itself cause cirrhosis, but augments the effect of Mn. The effect of CHCl_3 was inconclusive, but cirrhosis was produced in one case. Bile does not cause cirrhosis. None of these poisons produced degenerative changes in the central nervous system. Guanidine causes severe nerve cell degeneration and ameboid changes in neuroglia, but has no effect on liver. There is no evidence of connection between liver cirrhosis and cerebral changes which might throw light on hepato-lenticular degeneration.

JOHN T. MYERS

Drug action in galvanotropic responses. I. F. B. FRIES. Harvard Univ. *J. Gen. Physiol.* **11**, 507-13 (1928).—Strychnine produces reversal of the reciprocal inhibition of circular and longitudinal muscles of planarians (*Planaria maculata*, *P. velata* and *P. agilis*) and earthworms (*Allolobophora foetida*); in an elec. current the strychninized animals show reversed, i. e., anodal galvanotropic responses. Neither nicotine nor atropine induced reversed galvanotropic responses in planarians. Conclusion: Strychnine causes reversal of inhibition primarily through its action upon central synapses or homologous elements. *Asellus communis*, like other arthropods, is little affected by strychnine and even less so by caffeine and atropine. No reversal of galvanotropism occurs. Nicotine causes abnormal posture and movements which are perhaps reversed but no change of anodal galvanotropism.

C. H. RICHARDSON

Colloidal lead phosphate. A substitute for colloidal metallic lead in cancer therapy. FRITZ BISCHOFF AND N. R. BLATHERWICK. *J. Pharmacol.* **31**, 361-74 (1927).—To prep. colloidal lead phosphate, Na_3PO_4 is added drop by drop to a soln. of gelatin contg. Pb chloride at the b. p. The reaction is complete at p_H 7.4. The mixt. is centrifuged and filtered. The resulting colloidal soln. is sterilized by heating in vaccine bottles. The Pb content is 0.40%. For the prepn. of colloidal Pb oxide and carbonate, the procedure is the same, NaOH, and Na_2CO_3 being used. Colloidal metallic Pb added *in vitro* to blood satd. with oxygen was found to combine with all the dissolved oxygen at room temp., and with a small amt. of the oxygen combined with Hb at 37°. The degree of hemolysis was decreased. The Pb distributed itself between serum and cells. Colloidal Pb phosphate injected intravenously into rabbits caused no decided fall in Hb, and is, therefore, less toxic than the acetate, colloidal Pb, or colloidal Pb oxide. Ionic Pb (Pb acetate) mixed with serum or red blood cells contg. enough phosphate to react with the Pb was also non-toxic.

C. RIEGEL

Action of essential oils and of some of their constituents upon the formation of methemoglobin *in vitro*. EMMELINE DESSEMONTET. *J. Pharmacol.* **31**, 377-86 (1927).—The oils or constituents of the oils were added to defibrinated blood, either dild. with water or undild. at 37°. All the oils examd. caused the formation of methemoglobin from oxyhemoglobin (spectroscopic examn.). Of the constituents having an alc. group, those having an unsatd. side chain, like eugenol and safrol, form methemoglobin most quickly. Those with no unsatd. side chain react slowly or not at all (menthol, thymol). With terpenes, ketones and aldehydes, no relation was found between speed of formation of methemoglobin and unsatn. The amount of methemoglobin formed in blood at different oxygen tensions after the addn. of linalool, carvone and pinene was detd.; the greatest amount was formed at a definite oxygen tension specific for each of these constituents. No methemoglobin was found in the blood of white rats killed 6 weeks after injection of oil of clover, and oil of orange.

C. RIEGEL

The comparative effect of ethyl cyanide and ethyl isocyanide on biological oxidations. O. H. EMERSON AND J. WILLIAM BUCHANAN. *J. Pharmacol.* **31**, 387-92 (1927).—Ethyl cyanide, 0.0001 M and 0.0002 M, had no effect on the O consumption of *Planaria dorotocephala* or *Planaria maculata*. Ethyl isocyanide in the same concns. caused a depression in O consumption of about 8-14%.

C. RIEGEL

The adsorption of quinine by blood cells. O. S. GIBBS. Dalhousie Univ. *J. Pharmacol.* **33**, 185-90 (1928).—From 61 to 80% of quinine added to defibrinated blood

could be recovered, the quinine being distributed equally between serum and cells.

C. RIGGEL

Trials of pancreatic extracts in the course of experimental tuberculosis in the guinea pig. S. BONNAMOUR and P. DELORE. *Compt. rend. soc. biol.* **98**, No. 9 Séance, Feb. 20, Lyon, 598-9.—The subcutaneous injection of ext. of the pancreas of fowl had no favorable or unfavorable action on the evolution of exptl. tuberculosis in the guinea pig. The injection of insulin, repeated during several months, led in general to a prolongation of life, and appeared to cause an increase in the no. of endocrine pancreatic islets.

L. W. RIGGS

Action of adrenaline on the contractility of fatigued muscle in the rabbit deprived of suprarenals. FERREIRA DE MIRA and JOAQUIM FONTES. *Compt. rend. soc. biol.* **98**, 1011-3 (1928).—Adrenaline acts unfavorably on muscular contractility in the decapsulated rabbit. This action differs from that in the normal rabbit because the recuperation by rest is not reestablished. Muscles which have not been fatigued preserve their power of contraction. **New studies of the suprarenal capsules in their relation to muscular functions.** *Ibid* 1013-5. The substance produced by the suprarenals, which causes muscular debility in the decapsulated animal, acts on the muscle locally. Its precise mode of action was not detd.

L. W. RIGGS

Action in vitro of various alkaloids and chemotherapeutic products on trypanosomes. R. BRUYNOGHE and A. DE BOIS. *Compt. rend. soc. biol.* **98**, 1249-50 (1928).—Strychnine- HNO_3 , veratrine- AcOH , emetine- HCl , and quinine- HCl had a strong toxic action on trypanosomes *in vitro*; cocaine- HCl , atropine- H_2SO_4 , curare and eserine salicylate showed a moderate toxicity, while morphine- HCl and pilocarpine- HCl had no action. The concns. used varied from 1.0 to 0.01%, and the time of contact from 0.5 to 6.0 hrs. The results were somewhat irregular, depending on the nature of the blood, its degree of diln., and the no. of trypanosomes present.

L. W. RIGGS

Variations of chronaxie in the cataleptic state produced in the cat by the injection of bulbocapnine. GEORGES BOURGEOIS and H. DE JONG. *Compt. rend. soc. biol.* **99**, 55-7 (1928).—Action of bulbocapnine on the chronaxie in normal man. *Ibid* 57-9.

L. W. RIGGS

Effect of chronic strychnine poisoning on the number of erythrocytes. E. ANNAU and J. HERGLÖZ. *Monatsh. Chem. Arch.* **29**, 215-21 (1928).—Repeated injections of strychnine in rabbits caused a decrease in the no. of erythrocytes and a final death in tetanus. On the other hand if the spleen is removed the no. of erythrocytes is increased following the injection of strychnine, but this increase is transitory, and if the injections are continued the no. of erythrocytes is reduced.

L. W. RIGGS

The effect of caffeine upon the autolysis of the liver. AKIRA OHNISHI. *Sei i-Kwai Med. J.* **47**, No. 3, 1-1928. Both protease and peptase act under pH values ranging from 2.94 to 6.25. The optimum pH value for protease action is 3.24 and for peptase 7.20. Liver washed with saline soln. autolyzed more readily than liver contg. blood or caffeine. The latter in the amounts above indicated always inhibits the autolysis of the liver. **Mode of action by which caffeine inhibits the inhibitory action of decomposition products of protein on the proteolytic enzyme.** *Ibid* 2-3. Caffeine accelerates the activity of proteolytic enzymes because caffeine itself inhibits the inhibitory action of secondary albumose in the decomposition products of protein by forming a complex compd with the secondary albumose.

L. W. RIGGS

The influence of bolus suspension on drugs introduced into the blood vessels. NARANOSKE KÖNY. *Acta Schol. Med. Univ. Imp. Kyoto* **10**, 175-87 (1928).—The blood vessels of the legs of a frog were perfused with Ringer soln. contg. a certain quantity of a drug. When in this stage a colloidal soln. of bolus alba was added, the effect of the drugs causing contraction or dilation was varied, as seen by the change of the out-flow of the resp. soln. The expts. were performed at room temp., the drugs employed were adrenaline, NaNO_2 , cocaine, nicotine, morphine, caffeine, strophanthin, atropine, strychnine, digitonin and BaCl_2 . As to the first 7 drugs, bolus exerted an inhibitory action; while with the 4 latter, it increased their original medicinal effect. G. S.

The effect of insulin upon glycolysis and carbohydrate metabolism in the muscle. JUN HOMMA. *Japan J. Med. Sci. Sect. II*, **1**, 165-81 (1927).—In normal dogs the difference in the blood sugar between arteria and vena femoralis is 0.014%; in hyperglucemia produced by injection of adrenaline or glucose, it is 0.024%. In hyperglucemia caused by total pancreatectomy this difference is greatly diminished; on the av. it is 0.003%. This indicates that in diabetes, sugar consumption is decreased in the peripheral muscles. By giving insulin the difference in the blood sugar is brought back to normal. Expts. on normal rabbits show that insulin either injected or added *in vitro* has no effect on hemoglucolysis. In pancreatectomized dogs, the rate of glu-

colysis is greatly decreased, but is increased again by adding insulin to the blood or by a previous insulin injection. The lipid content of the blood has no influence upon the glucolysis. As to human beings, H. differentiates between mild diabetes with a normal glucolysis and almost normal difference in the blood sugar content between venous and arterial blood, and severe diabetes with a decreased rate of glucolysis and a greatly reduced difference of the blood sugar. In this type of diabetes nearly always a histological change in the pancreas can be detected. Insulin when given subcutaneously brings "blood sugar difference" and glucolysis back to the normal state; *in vitro*, it is of little influence. G. SCHWOCH

Serochemical studies on the parenteral administration of proteins foreign to the species. TAKU ASAKURA. *Japanese J. Med. Sci. Sect. II* 1, 183-220 (1927).—Parenteral injections of sterilized milk or sterilized casein soln. were given to rabbits and the serochemical changes observed. After one injection the non-protein nitrogen, amino acid N, fibrinogen, lecithinase, blood sugar, catalase and protease increased. Serum protein (albumin and globulin), ethylbutyrase and antitrypsin decreased; diastase remained unchanged. Complement and normal amboceptor did not change distinctly. After a second injection of casein, the non-protein N, amino acid N, blood sugar and ethylbutyrase showed an increase, while diastase remained unchanged. Catalase and protease increased but to a smaller extent than after the first injection. G. SCHWOCH

Permeability of the liver to some colloidal substances. DANIEL ALPERN. *Arch. ges. Physiol.* (Pflüger's) 218, 610-26 (1928).—When cholesterol is given to dogs by mouth a cholesterolemia of different degrees follows, the degree depending upon the rate at which the fat in which the cholesterol is incorporated is absorbed from the intestine. In dogs with a chronic pancreatic diabetes the blood cholesterol fluctuates within very wide limits, sometimes attaining a normal level. In both normal and diabetic dogs the hypercholesterolemia is not always accompanied by an increased excretion in the bile. After several injections of phlorhizin the cholesterol of the bile is diminished although there is a hypercholesterolemia. Removal of the pancreas increases the excretion through the bile almost 2 fold. Cholesterol emulsions injected intravenously (femoral vein) into normal dogs cause no increase in biliary excretion, and in diabetic dogs cause but a slight, transitory increase in the daily excretion. Emulsions injected directly into the liver through the hepatic vein result in complete retention of the cholesterol, but during pancreatic diabetes such an administration increases the excretion through the bile. The ratio between the blood sugar and that of the bile in diabetes depends upon the degree of cholesterol excretion by the bile. In pancreatic diabetes a more marked excretion of intravenously injected colloidal dyestuffs and colloidal Fe takes place than in the normal animal. Disturbances in the carbohydrate metabolism in pancreatic diabetes result in an increased permeability of the liver for cholesterol. G. H. S.

Adsorption and narcosis. FERD. HERCIK. Russian Zoological Lab., Villefranche sur Mer. *Protoplasma* 3, 417-25 (1928).—The young dark green assimilators of *Caulerpa prolifera* were ground, the sap was expressed and dild. 10 times with distd. H₂O. The surface tension of the sap was detd. by means of Du Nouy's tensimeter. The adsorption was measured on the differences of surface tension with equicapillary solus of alcs. The alcs were adsorbed in an indirect relation to their respective capillary activities against air. It was supposed that the unadsorbed remainder is a regulating device to remove the narcotizing substance from the more liquid phase of the cell interior. The validity of Traube's rule for narcosis as a biol. phenomenon can be understood on the basis of the fact that the strongly capillary active substances are adsorbed least and the poorly capillary active substances most. Thus their narcotizing effect is indirectly proportional to their respective adsorbility. M. H. SOULE

Use of histamine as a standard test for diminished resistance in suprarenalectomized rats. J. MARMORSTON-GOTTESMAN AND J. GOTTESMAN. *J. Exptl. Med.* 47, 503-14 (1928).—Of all the drugs thus far used in testing the resistance of suprarenalectomized rats, histamine has been found to be the most satisfactory. It is a readily obtainable and comparatively stable drug, producing characteristic symptoms. Its m. l. d. for a given strain of rats can be established within narrow limits and the difference between the m. l. d. for normal and suprarenalectomized rats is comparatively great (1:20). C. J. WEST

Studies of the action of sodium thiosulfate in metallic intoxications. I. The effect of sodium thiosulfate on arsenic elimination. A. G. YOUNG. *J. Lab. Clin. Med.* 13, 622-8 (1928).—The opinion is expressed by many that Na₂S₂O₃ is the "ideal" antidote for arsenical poisoning. This is shown not to be the case by expts.; in most instances the thiosulfate markedly diminishes the rate of arsenic excretion and has

never increased it even when there is pronounced diuresis. Exptl. work on rabbits indicates that the drug has some value in preventing kidney damage in chronic intoxication but that its value as an antidote when large amts. of As have been ingested is questionable. II. The effect of sodium thiosulfate upon the excretion of lead. A. C. CURTIS AND A. G. YOUNG. *Ibid* 628-32.— $\text{Na}_2\text{S}_2\text{O}_3$ given by mouth in doses of 0.5 g. per kg. body wt. to guinea pigs, rabbits and rats previously poisoned by Pb does not appreciably affect the excretion of Pb. Results obtained would indicate that any other alk. drug would give the same results as those obtained with $\text{Na}_2\text{S}_2\text{O}_3$. E. W. W.

The effect of sodium salicylate on the normal human electrocardiogram. ARTHUR M. MASTER. *Am. Heart J.* 3, 180-9(1927).—Twelve men and 1 woman who had no disease which affected the heart were studied. Electrocardiographic records were taken before and after the administration of Na salicylate. The salicylate was given by mouth and by rectum until signs of salicylism appeared. The electrocardiogram was not changed by sodium salicylate and there is no evidence that the drug has any effect on the normal heart muscle.

R. C. WILLSON

Studies of respiratory effects of anesthetics. I. A comparison of irritant and non-irritant types. M. S. DOOLEY AND CHAS. J. WELLS. *Anesthesia and Analgesia* 6, 278-84(1927).—Two cannulae were placed in the trachea of a rabbit under local anesthesia. Liquid anesthetics were administered in a gaseous form by admixt. with a current of air. The arrangement of the cannulae permitted application of the anesthetic to the upper or lower part of the trachea. Ethyl chloride and CO_2 mixed with ethyl and methyl chlorides and ethyl bromide and chloroform exerted local effects not unlike chloroform and ether. CO_2 in conns. required to anesthetic or even to counteract alcoholic or other narcotic intoxication exerted a local irritating effect. N_2O had no more local effect than air. A group of the ethylene type had very minor local effects but was otherwise similar to N_2O . The authors believe that the results reported support the Schmiedberg primary depression theory.

R. C. WILLSON

A preliminary report on the postoperative use of aromatic spirits of ammonia. OSCAR H. STOVER. *Anesthesia and Analgesia* 7, 77-9(1928). Rabbits and cats were anesthetized by injecting equal parts of ether and oil into the peritoneal cavity. Aromatic spirits of ammonia were administered by holding a satd. gauze before the nose for 30 sec., repeating after an interval of 4-5 min. if deemed necessary. Aromatic ammonia stimulates reflexly the respiration and circulation of animals under ether anesthesia. The reflex stimulation varies inversely with the depth of the anesthesia. The reflex arises mainly in the mucous membranes of the nose, as cocainizing the nose abolishes the reflex. Repeated administrations of the drug at intervals repeatedly increases the respirations. Administration of the drug to animals under deep anesthesia often causes them to cry out and give evidence of waking up. Since the effect appears quickly after administration, it may be due to direct cerebral stimulation. The drug administered by inhalation shortens the postanesthetic recovery time. It is a reflex respiratory and circulatory stimulant and may be used to advantage following many anesthetics. The use of the drug tends to decrease shock and vomiting in caudal and spinal anesthetics.

R. C. WILLSON

A study of sugar metabolism in animal cells with special reference to the effect of anesthetics. A. M. ESTES AND W. E. BURGE. *Anesthesia and Analgesia* 7, 79-81(1928).—*Paramoecium caudatum* was introduced into 0.1% sugar solns. and anesthetics in gaseous form were bubbled through the soln. Chloroform and ether decrease sugar metabolism, whereas N_2O and C_2H_4 do not unless they are used with a very limited supply of O. The limited supply of O alone decreased sugar metabolism so N_2O and C_2H_4 have no effect on sugar metabolism.

R. C. WILLSON

The chemical basis of the efficacy and toxicity of local anesthetics. JOHN S. LUNDY AND ARNOLD E. OSTERBERG. *Anesthesia and Analgesia* 7, 141-51(1928).—Practically all local anesthetics that are used extensively at present are alic : i. e., they contain at least 1 OH group. This may be either free or substituted and either an alic or phenolic type. Furthermore, most of them contain a free or substituted amino group. The anesthetic coefficient is generally increased by esterification of the alic OH. Benzoic acid or substituted benzoic acids are usually used for the esterification. After injection the first reaction is the liberation of the base from its salts by the body fluids and in this form it is lipid-sol. and exerts its effect on the nerve fibers. Nine general types of anesthetics are suggested based on certain similarities in structure. The groups: cocaine, tropacocaine, piperidine, procaine, apothesine, benzyl alc., ecaine, anesthesine and quinine.

R. C. WILLSON

The preparation of 4-chaulmoogrylamino benzene arsonic acid (DEWAR) 17. The

preparation of chaulmoogryl alcohol (DEWAR) 17. The synthesis of iododihydrochaulmoogric acid and its ethyl ester (DEAN, *et al.*) 17.

R. A. GORTNER

Digestive processes in protozoa. Study on *Paramecium caudatum*. HANS FORTNER. *Arch. Protistenk.* 61, 282-92(1928).

FRANCES KRASNOW

The action of carbon dioxide on water organisms. T. NIKITINSKII. *Centr. Bakt. Parasitenk., II Abt.* 73, 481-3(1928).—A satd. soln. of CO₂ (about 2%) at 15° killed diatoms, cyclops and daphnia in 10 to 40 sec.; the larvae of *Chironomus plumosus*, ceratopogen and *Corethra plumicornus* in 30 to 60 sec.; and nematodes, *Rotifera vulgaris* and *Chilton uncinatus* in 3 to 10 min. Death is not due to the H ion. The more saprophytic organisms are more resistant.

JOHN T. MYERS

Ability of certain marine invertebrates to live in diluted sea water. A. S. PEARSE. *Biol. Bull. Marine Biol. Lab.* 54, 405-8(1928).—*Limulus*, *Phascolosoma* and 18 marine annelids lived a week or two in a mixt. of $\frac{3}{4}$ sea water and $\frac{1}{4}$ fresh. Several species lived in $\frac{1}{2}$ sea water. *Limulus*, *Leoneice* and *Nereis* were active for 2 to 3 weeks in $\frac{1}{4}$ sea water, but died in weaker solns.

L. W. RIGGS

Variations in the content of amino acids of certain lepidoptera during nymphosis. (MLLE.) ANDRÉE COURTOIS. *Compt. rend.* 186, 1575-6(1928).—Chrysalides of *Saturina carpin*, *Attacus cyathia*, *A. Pernyi* and *Sphinx pinastri* were ground and extd. with cold water. The ext. was defecated with CCl₃CO₂H and the amino acids were detd. by the method of Sørensen. The content of amino acids remains at about 2.5 g. per kg. until the time of forming the tissues of the perfect insect when there is a rapid diminution of this figure notwithstanding a pronounced loss of wt. of the chrysalides.

L. W. RIGGS

Action of various gases on the egg of the fowl. Assimilation of carbon monoxide as an inert gas. (MLLE.) SUZANNE ANCEL. *Compt. rend.* 186, 1579-80(1928).—Eggs placed in jars contg. pure CO and sealed for 8 days were allowed contact with the atm. for 24 hrs. and were then incubated. CO behaved as an inert gas like N, H or O₂, in that the eggs developed normally. Eggs exposed to H₂S, NH₃, HCl, SO₂, Cl, C₂H₂, CO₂ or illuminating gas for varying periods of time developed abnormally or not at all.

I. W. RIGGS

Elimination of urea by batrachians. ALFRED SCHWARTZ. *Compt. rend. soc. biol.* 98, 1552-4(1928).—The urea excretion of *Rana temporaria* after retention for 15 to 17 hrs. was detd. in *a*, frogs totally immersed in water, *b*, the ventral portion only immersed and *c*, kept in air. In 7 frogs of series *a*, the urine for 24 hrs. ranged from 8.3 to 29.5 cc., concn. of urea per 1000 of urine 0.32 to 0.73, output of urea in mg. per 24 hrs. 4.4 to 21.5, concn. of urea per 1000 of blood 0.72 to 1.5. In 4 frogs of series *b*, the urine for 24 hrs. averaged about $\frac{1}{2}$ that of the series *a*, concn. of urea 0.66 to 0.87, output for 24 hrs. 4.9 to 8.6 mg. and the blood urea 0.72 to 1.6. Two frogs, *c*, kept in air gave 2.6 and 5.5 cc. of urine in 24 hrs. with a concn. of urea of 1.35 and 1.14 per 1000 of urine; the output of urea for 24 hrs. was 3.5 and 6.2 mg. and the concn. of urea in the blood was 1.6 per 1000.

L. W. RIGGS

Chemical regulation of the respiration in the sloth (*Bradypus tridactylus*). MIGUEL OZORIO DE ALMEIDA. *Compt. rend. soc. biol.* 98, 1576-8(1928).—The chem. regulation of respiration by CO₂ in the sloth follows the same laws as that in ordinary lab. mammals. Although this animal presents variations in many functions it appears normal concerning its respiration.

L. W. RIGGS

12—FOODS

F. C. BLANCK AND H. A. LEPPER

Bacteria count limits and the transportation of milk. JAMES D. BREW AND RICHARD C. FISHER. Cornell Univ. Agr. Expt. Sta., *Bull.* 460, 1-37(1928).—A general discussion. Bacterial-count tolerance cannot be always complied with and the main purpose of such regulations is to compel better care in handling milk. A mass of inconclusive data is compiled in 28 tables.

C. R. FELLERS

The possibility of producing iodized milk. C. F. MONROE. Ohio Agr. Expt. Sta., *Bimonthly Bull.* 13, 153-6(1928).—The milk of the Expt. Sta. herd of cows has not contained a demonstrable amt. of I for a period of 2 yrs. The amt. present is believed

to be less than 10 parts per billion. Feeding tests with KI, CaI_2 , and dulce (a sea weed), when fed at the rate of 2 grains daily, showed I present in the milk in amts ranging from 10 to 100 parts per billion. C. R. FELLERS

The bacteriology of dried powdered milk preparations used in infant feeding G. F. AND G. H. DICK. *Am. J. Diseases Children* 34, 1040-1 (1927); *Expt. Sta. Record* 58, 594.—The presence of a variety of living bacteria, including streptococci, in preps of powd. milk indicates that the methods of manuf. do not destroy the bacteria in the milk and that the bacteria remain viable in the powder. The prepn. of powd milk feedings without boiling or pasteurization in order to avoid curdling allows the bacteria in the powder to persist in living form in the feeding. H. G

Investigations on the bacterial and enzyme content of condensed milk. GERTRUI GEHRI. *Mill. Lebensm. Hyg.* 19, 89-101 (1928).—Swiss condensed milk samples were good as to taste and smell, but none was sterile. The bacterial count varied between 10 and 9000, mostly harmless organisms. There is always a difference in bacteria count between sweetened and unsweetened milk, preponderance apparently changing with different methods of process. The Swiss condensed milk contains only exceptionally traces of oxidases and reductases. J. C. JERRJENS

The purification of skim milk solutions on a lath filter. M. LEVINE, G. W. BURKE AND C. S. LINTON. *Iowa Eng. Expt. Sta., Bull.* 81, 30 (1926); *Expt. Sta. Record* 58, 185.—Studies are reported which showed that a plant for the purification of creamery wastes must be capable of rapidly destroying milk sugar without developing detrimental acidities. Anaerobic methods such as septic or Imhoff tanks are not suitable, whereas aerobic devices such as trickling filters provide the conditions necessary for the rapid oxidation of milk sugar and org. acids. Results obtained by applying various dilns. of skim milk to a small lath filter at 2 rates are reported on the removal of solids, O-consuming constituents, org. N, on the O consumption, ammonification, nitrite and nitrate formation and on the stability of the effluents. The effluents were considerably more alk. than the applied wastes. Anaerobic storage of the raw wastes resulted in distinctly acid reactions. E. H

Lipins and sterols as sources of error in the estimation of fat in buttermilk by ether extraction methods. L. M. THURSTON AND W. E. PETERSEN. *J. Dairy Sci.* 11, 270-83 (1928).—The gravimetric method of fat detn., when applied to buttermilk, gives results which are higher than the true fat content by the amt. of non-saponifiable matter and lecithin present in the product tested. Inasmuch as the A. O. A. C. test or the Bu alc. test detcs. the % of lecithin and fat when both are present, it is inaccurate, and should be discontinued. The Babcock method was shown to be the most accurate for a product such as buttermilk contg. roughly as much lecithin as fat. With buttermilks below 0.3% fat the results are often considerably too low. The Gerber method also yields incorrect results, using Am alc. instead of Bu alc. and showing the same errors as the Babcock test. Results of expts. are extensively tabulated. J. C. JERRJENS

A study of the proteolytic action of specific organisms and groups of organisms in butter made from graded cream. GEORGE SPITZER, E. F. PAKFITT, V. C. MANHART AND WM. F. EPPLE. *Purdue Univ. Agr. Expt. Sta., Bull.* 319, 1-36 (1927); cf. *C. A.* 21, 1153.—Chem. methods of detg. protein hydrolysis together with bacterial methods and arbitrary butter scores were used on about 100 samples of butter to show the relation of the several predominating factors influencing the flavor and general quality of butter held in storage. The quality decreased in proportion to protein hydrolysis, and proteolytic hydrolysis progressed at a greater rate in the presence of proteolytic organisms such as *B. liquefaciens*, *B. butyricus* and *B. proteus vulgaris*. Salting of butter, contrary to popular belief, had no influence in retarding proteolysis though the growth of some microorganisms was retarded by salt. This retardation was insufficient to retard protein hydrolysis. The p_H value of butter when going into storage was one of the most important factors controlling its keeping value. An optimum p_H value of from 5 to 6 is suggested. C. R. FELLERS

The determination of butter fat in cooking fats containing butter. HEINRICH WILDI. *Mill. Lebensm. Hyg.* 19, 102-16 (1928).—The accuracy of the "A" and "B" nos., and butyric acid no. methods was tested on samples of fat- and oil-mixt. to which a known amt. of butter had been added. Mixt. with coconut oil causes the butyric acid no. to give too low butter values. It was proved theoretically and exptly. that this low value must be attributed to the variety of the butyric acid no. of the coconut and palm oils. The sapon. no. cannot compensate for this error. Satisfactory results can be obtained if only half the amt. is taken for analysis. The disadvantages of the detn. of the "A" and "B" nos. are large amt. of time and expense of reagents. The

modification of Kuhlman and Grossfeld and using half the amts. for analysis give accurate percents of butter fat. J. C. JURRIJENS

A contribution to the question concerning the influence of the amount of added salt upon the changes taking place in cheese. E. HAGLUND, A. SILFVERSPARRE AND E. SANDBERG. *Medd. Centralanstalt. forskväsendet jordbruks. Mejeriförsök 34; Bakteriöl. avdel. 46*, 3-21(1928).—An investigation of the effect on certain bacteriol. and chem. changes in cheese resulting from the method of salting employed. Half of the curd was salted as soon as the whey had been removed after which it was pressed. At the same time the other half of the curd was pressed for 2 days and then salted in a brine bath. The lactose and bacterial contents as well as the p_H of the cheese were detd. at different intervals. In the cheese which had been immediately salted the salt had a marked retarding effect on the bacterial growth, the bacterial count in no case reaching as high a value as in the cheese salted after 2 days. The difference in the 2 types of cheese became more noticeable with increase in the content of salt. Four % or more of salt in the moisture in the immediately salted cheese resulted in a hard, brittle and crumbly consistency, while the cheese salted after 2 days showed no appreciable effect on its consistency with a moisture contg. as high as 8% of salt. E. O. E.

A comparison of the volatile-solvent method with the vacuum-oven method for determining moisture content of cheese. GEORGE P. SANDERS. *J. Dairy Sci.* 11, 325-30(1928).—Toluene removes moisture rapidly without causing undue charring or decompn. and is recommended. Collodion-coated corks, correction for density of water, and using a paraffin or glycerol bath at 140° to 150° increase the efficiency of the method. The results are slightly higher than those obtained by the vacuum oven method. With the rate of boiling properly regulated, it is undesirable to boil longer than 1½ hrs. Closer checks are obtained on duplicate samples by the vacuum-drying method, but the distn. method is much more rapid and is very accurate for detns. on cheese. J. C. JURRIJENS

A new process of bread-making. GIULIA DROGOU. *Atti II congresso naz. chim. pura applicata 1926*, 376-80.—The Monti process, the principles of which and the application to wheat bread have already been described (cf. D., C. A. 17, 3726), is also suitable for the prepn. of whole-corn bread. New expts. are described in which the process was utilized for the prepn. of corn bread by several formulas. In this case the bran was treated with grape juice, which increased slightly the content of sol. proteins and increased notably the total sol. substances and the reducing sugars. C. C. DAVIS

New methods of bread-making. EUDO MONTI. *Atti II congresso naz. chim. pura applicata 1926*, 393-408.—A review of recent developments (cf. Drogoul, C. A. 17, 3726 and preceding abstr.) As representative applications of the Monti process, (1) the mixt.: wheat flour (75% yield) 90 parts, corn meal 6 parts, unfermented grape juice 4 parts, which yields 116 parts of bread contg. 28% moisture, which is white and keeps exceedingly well, and (2) the mixt.: wheat flour (75% yield) 75, bran (disintegrated with corn oil) 6, corn meal 7, unfermented white grape juice 4, neutral corn oil 10, which yields 110 parts of product contg. 10-12% moisture, are given to show the economy possible with the process. C. C. DAVIS

Flours suitable for bread-making and the control of the yield of bread. STEFANO CAMILLA. *Atti II congresso naz. chim. pura applicata 1926*, 381-92; cf. C. A. 20, 2549.—A crit. review and discussion of present knowledge and important problems of research, with references to past and present research at the Royal School at Turin. Under ordinary conditions, 12% is about the min. gluten content of a flour from which satisfactory bread can be made. Expts. show, however, that it is possible to prep. satisfactory bread from a flour contg. less than 12% gluten if this deficiency is compensated by the addn. of a suitable quantity of certain protein substances. For this purpose, skimmed milk powder gives particularly good results, and with this ingredient the bread stays fresh an unusually long time. C. C. DAVIS

Mass production of yeast for feeding purposes. H. CLAASSEN. *Chem. Ztg.* 52, 407(1928).—The cost estus. of yeast from various sources of supply have been made by Stich (C. A. 22, 3016). They are erroneous. German materials cannot compete with foreign ones. A. L. HENNE

Effects of the constituents of the yeast cell in the fermentation of dough. M. BARTSLÉ. *Bull. assoc. élèves inst. sup. fermentations Gand* 29, 240-8(1928).—A brief review. A. PAPINEAU-COUTURE

Hungarian paprika (red pimento). ANON. *Ann. fals.* 21, 210-5(1928).—Text of the official Hungarian definition, description, methods of analysis and standard. A. P.-C.

The identification of foreign honey by bacteriological method. CH. SCHWEIZER.

Mitt. Lebensm. Hyg. 19, 117-25(1928).—Practically all Swiss honeys were found to be free from bacteria, as were also several of French origin. A large no. of Swiss honeys as well as several foreign brands were examd. bacteriologically and results are tabulated. It is concluded that a bacteriol. examn. does not show the origin of the honey.

J. C. JURRYENS

Carotin: a pigment of honey. H. A. SCHUETTE AND PHYLLIS A. BOTT. Univ. of Wisconsin. *J. Am. Chem. Soc.* 50, 1998-2000(1928).—At least 1 of the pigments of buckwheat honey can be isolated with petroleum ether in the presence of EtOH and CaSO_4 , a method applied by Palmer in the removal of pigments from blood serum, and this pigment is carotin.

C. J. WEST

The nutritive value of swedes, marrow stem kale, and sugar beet tops. T. B. WOOD. *J. Min. Agr.* 34, 697-705(1927); *Expt. Sta. Record* 58, 565.—A new formula was used in these calcs.: $R = M + GK$, in which R equals the av. ration per head per week in lbs. of starch equiv., M the av. maintenance requirement in lbs. of starch equiv., G the av. live wt. increase per head per week in lbs., and K the wt. in lbs. of starch equiv. required to make 1 lb. of live weight increase. This equation has been found to be justified if the animals are quiet and do not waste too much starch equiv. in movement. R can be calcd. from the ration and G from periodical weighings. M and K can be read from curves previously calcd. by the author (*J. Ministry Agr.* 34, 295-307(1927)). From these calcs. it was found that the starch equiv. per 100 lbs. of Norfolk swedes was 5.84 lbs., Fen swedes 5.15, marrow stem kale 7.14, and sugar-beet tops and crowns 8.8 lbs.

H. G.

Chemical injury to watermelons in transit. W. W. GILBERT AND F. C. MEIER. *Phytopathology* 16, 73(1926); *Expt. Sta. Record* 58, 552.—Expts. conducted to det. whether any chemicals carried as freight might damage melons indicated that after 5 days melons under pressure showed marked injury, such as discoloration, pitting, and softening, when in direct contact with acid phosphate, K muriate, common salt and NaNO_3 . Some damage resulted under the same conditions from $(\text{NH}_4)_2\text{SO}_4$ and K_2SO_4 . Neither hydrated lime nor air-slaked lime caused any injury.

H. G.

A relation between the concentration of oxygen and carbon dioxide in the atmosphere, rate of respiration and length of storage life in apples. F. KIDD AND C. WEST. *Dept. Sci. and Ind. Res., Food Invest. Bd. Rept.* 1925-1926, 41-2, *Expt. Sta. Record* 58, 540; cf. *C. A.* 20, 1283.—By comparing the rate of respiration, as measured by loss of weight, of apples stored in air and in gas (12% CO_2 and 9% O_2) it was found that respiration was approx. halved and the length of storage life approx. doubled in gas storage. The relations between O_2 concn. and the respiration rate as detd. by the amt. of CO_2 evolved were for 10 and 5% of O_2 0.86 and 0.78, resp., as compared with unity for normal air.

H. G.

Determination of malic and citric acids in fruit juices and jams by Muttelet's method. (Miss) CONCHA ESPESO. Lab. Municip. Paris. *Ann. fals.* 21, 201-3 (1928); cf. Muttelet, *C. A.* 16, 3142.—The sources of error in the technic described by Muttelet are: incomplete elimination of pectic matter because of addn. of insufficient alc., incomplete elimination of Ba malate from the mixed Ba salts, partial repptn. of Ba malate in the purification of Ba citrate by double pptn., Ba malate is not completely insol. in alc. of the strength recommended by Muttelet. To overcome these errors, the following technic is recommended. To 1 part of jam or juice soln. (corresponding to an acidity equiv. to 5.6 cc. N NaOH) add 2 vols. of 95% alc., let stand a few hrs., filter off the pectic matter, neutralize the filtrate with NaOH in presence of phenolphthalein, add 25-30 cc. of BaBr_2 in 80% alc., filter, wash with 80% alc., redissolve the ppt. in as small a quantity as possible of very dil. aq. HCl , dil. to 100 cc., neutralize with NaOH , make to 125 cc., gradually add 63 cc. of 95% alc. while stirring, let stand a few hrs., filter, wash with 33% alc., redissolve and reppt. as before, weigh the ppt. of Ba citrate and test it for the presence of Ba malate by Pinerua's reaction (heating with 0.2 g. β -naphthol dissolved in 1 cc. concd. H_2SO_4 gives a green fluorescence). Combine the filtrates from the 2 pptns., evap. to 25 cc., add 2 vols. of 95% alc., filter, wash with 80% alc., weigh, and test with Pinerua's reagent to make certain it is Ba malate. Pptn. of citric acid is never complete, 20-30 mg. remaining in soln., while some malate (when present) is always carried down with the citrate, so that the values found for citric acid are usually somewhat high. The error was found to be -7 to +20 mg. per 100 g. of jam or juice.

A. P.-C.

A relation between the sugar and nitrogen content of the apple at the time of gathering and the length of its subsequent life in storage. D. HAYNES AND H. K. ARCHBOLD. *Dept. Sci. and Ind. Res., Food Invest. Bd. Rept.* 1925-1926, 42-5; *Expt. Sta. Record* 58, 540; cf. *C. A.* 20, 1283.—The demand that an apple make on its stores

of respirable material is regulated almost entirely by its N content. Sugar intake is deemed to be largely dependent on seasonal conditions during the growing period. In storage at 34° the supply of sucrose is believed to be the limiting factor in the life of the apple. When the supply of sucrose in process of inversion gives out, acids are drawn upon but cannot entirely offset the deficiency, and internal breakdown results.

H. G.

Pectic changes in apples and pears. A. M. EMMETT. *Dept. Sci. and Ind. Res., Food Invest. Bd. Rept.* 1925-1926, 47-9; *Expt. Sta. Record* 58, 540.—The general chemical processes in stored pears were very similar to those in apples. In pears stored at 39° F. there was a steady decrease in total pectic content during the entire storage period. Low temp. (34°) tended to inhibit the development of sol. pectin in pears much more than in apples, a difference believed to explain the contrasting behavior of pears and apples in storage. In pears at 39° practically the whole of the cell wall losses were due to pectin losses, whereas in the apple, even at 34°, cell walls suffered other losses presumably by hydrolysis of the cellulose, suggesting differences in the nature of the pectin cellulose compds. in the cell walls of the pear and apple.

H. G.

The commercial production of sauerkraut. EDWIN LEFEVRE. U. S. Dept. Agr., *Circ.* 35(1928).—Sauerkraut is defined as the clean, sound product of characteristic acid flavor obtained by the full fermentation, chiefly lactic, of properly prep'd. and shredded cabbage in the presence of not less than 3% salt. It contains upon completion of the fermentation not less than 1.5% of acid expressed as lactic acid. Sauerkraut which has been rebrined in the process of repacking contains not less than 1% of acid expressed as lactic acid. The av. compn. of cabbage is H₂O 91.1, crude protein 1.5, fat 0.1, sugars as dextrose 4.2, crude fiber 1.1 and ash 0.8%. Vitamins A and B are probably retained uninjured in the finished kraut but C is largely destroyed by the fermentation process. The bacterial species largely responsible for sauerkraut fermentation is *Lactobacillus brassicus*. The use of pure cultures or starters in the manufg. process is not recommended. A preliminary heating of the kraut stock to 27-30°, the optimum fermentation temp., was found decidedly advantageous. The proper quantity of NaCl is 2.5% of the wt. of shredded cabbage. Pathogenic or toxicogenic bacteria are usually not associated with sauerkraut, which forms an unfavorable medium for their development. Swells in canned sauerkraut may be due either to gas-producing microorganisms which were not destroyed by the processing operation or to H caused by acid-metal action. Cool temps. are essential for storing canned sauerkraut.

C. R. FELLERS

Flavor of maple sirup. F. K. NELSON. Dept. Agr., Washington, D. C. *J. Am. Chem. Soc.* 50, 2009-12(1928).—The flavor of maple sirup depends to a great extent on an unstable phenolic substance which is associated with a cryst. aldehyde, m. 74-6°, and similar in odor and properties to vanillin. Maple sirup may contain minute quantities of other aldehydic substances which influence the flavor.

C. J. WEST

Can the use of aluminum cooking utensils be recommended from a hygienic standpoint? TH. VON FELLEBERG. *Mitt. Lebensm. Hyg.* 19, 137-47(1928).—Very little Al is taken up by food prep'd. in Al cooking utensils. It is recommended to clean Al pans, that have been unused for a long time, with acid and then to polish with sand. Acid fruit should not be boiled to sirupy consistency, and scale should always be removed from a kettle before cooking acid foods in them.

J. C. JURKJENS

The deterioration of the oils of feeding stuffs. W. L. DAVIES. *Fertilizer, Feeding Stuffs and Farm Supplies J.* 12, 389-91(1928).—The taints most frequently encountered in deteriorated feeding stuffs are abnormal acidity, rancidity and mustiness. The causes of these and their prevention are discussed. In general, feeds high in protein, or oil, deteriorate most rapidly when stored under humid conditions. In some cases rancidity in oils is due to contamination of the residual fat by minute traces of metals, such as Fe and Cu, particularly if solvent extn. methods are used.

K. D. JACOB

Iron-starvation (bush sickness) in stock. B. C. ASTON. *New Zealand J. Agr.* 36, 316-8(1928).—The results of practical experiences on the application of FeSO₄ to soils and of feeding of Fe citrate to stock as measures for prevention of iron starvation in stock in certain N. Zealand districts are summarized. Both methods give good results.

K. D. JACOB

The chemical composition and digestibility of different cuttings of alfalfa. E. NEDOCHETOVA AND N. GORJAINOVA. *Izvestiya Saratovsk. Gosud. Inst. Selsk. Khos. i. Melior.* 1927, 99-105; *Expt. Sta. Record* 58, 564-5.—Digestion trials with sheep were made to det. the value of 4 cuttings of alfalfa hay. The first cutting was made before blooming time at the end of May and at blooming time in early June, the second cutting before blooming at the end of June, the third when blooming began at the end of July,

and the fourth when blooming began at the end of August. The coeff. of digestibility of all the components was detd., and from these coeffs. the amt. of each component digested was calcd. and the figures were converted into starch values, 1 g. of crude fiber being used as equiv. to 0.58 g. of starch. The starch value of hay cut before blooming was higher than that of hay cut after blooming. The feeding value of the different cuttings varied but little, although there were differences in the chem. compn. First cutting hay was lower in albumin, fat and N-free ext. but higher in ash and cellulose than second cutting. The starch values of the third and fourth cuttings were approx equal. H. G.

Food mixture. LOUIS SOKOLSKY (to ALBERT K. EPSTEIN). U. S. 1,676,166, July 3. Wet casein and liquefied coconut oil are mixed, chilled and comminuted and then solidified into a self-sustaining mass.

Food product. ALBERT K. EPSTEIN. U. S. 1,676,138, July 3. A mixt. suitable for preservation or shipment is formed from wet pressed casein 80, coconut oil 18.7, and edible hydrogenated cottonseed oil 1.3 parts, homogenized together.

Enzymic composition for use in bread-making. HENRY A. KOHMAN, ROY IRVIN and ERNEST S. STATELER (to the Fleischmann Co.). U. S. 1,676,446, July 10. *Aspergillus oryzae* is cultivated upon a moist mass of ground hominy contg. 1.4% of lactic acid.

Baking yeast. H. CLAASSEN. Brit. 280,861, Nov. 19, 1926. A "mother yeast" is grown in a soln. prepd. from malt and malt sprouts, contg. only org. N. From this mother yeast, 2 or more cultures are prepd. in molasses soln. with increasing addns. of inorg. N nutrients so that the yeast has a successively increasing proportion of albumin. The last yeast contains 55% or more albumin and may be used as "store yeast" without being compressed. The "store yeast" in semi-liquid state may be fermented in a molasses soln. to produce baking yeast, sepd. and pressed.

Baked food including "non-acidosis producing odd-carbon fatty acids." HATTIE L. HEFT, MAY B. VAN ARSDALE and DOROTHY E. SHANK (to Teachers College). U. S. 1,676,899, July 10. A food suitable for use in cases of diabetes comprises acids such as undecylic, tridecylic, pentadecylic, heptadecylic, or like acids which may be mixed with gluten flour, baking powder, egg white, skim milk, salt and water and flavoring substances such as cocoa or cheese and baked into crisp wafers which do not have the unpleasant taste of the odd C fatty acids themselves.

Cheese from pieces of curds. RICHARD VON DER HEIDE. U. S. 1,676,121, July 3.

In forming cheese by use of salts and the action of bacteria, a mixt. is employed comprising amino acids 50, NaCl 40, $MgCl_2$ 4, Ca phosphate 4, Fe salts 1 and Mn salts 1%.

Treating cereals. L. BARTMANN. Brit. 280,605, May 18, 1926. In steeping cereals in water to cause the endosperm to swell, CH_2O is added or rapid changes are made in the temp. or mech. or elec. shocks are utilized for the purpose of killing the embryos or germs of the cereals. Various details are given for treating rye and wheat. Cf. C. A. 22, 830.

Sausage casing. RALPH EITTLINGER. U. S. 1,676,082, July 3. Fabric suitable for sausage casings, such as muslin or cheesecloth, is coated on one side with a substance contg. gelatinized raw hogskins, which may be prepd. by boiling the skins with an aq. soln. of glycerol and salt, and is then subjected to the drying, setting and preservative action of wood smoke.

Precautions to be observed in handling high-pressure oxygen. W. BUCHANAN GRAY. *J. S. African Chem. Inst.* 10, 51-2 (1927).—The usual precautions necessary in handling compressed O_2 are stressed. ALBERT THOMAS FELLOWS

Flow of heat through limestone and lime. R. T. HASLAM AND V. C. SMITH. Mass. Inst. of Technology. *Ind. Eng. Chem.* 20, 170-4 (1928).—An application of the work of Gurney and Lurie (C. A. 17, 3809) to a case where heat is generated or liberated by a reaction. Slabs of limestone were provided with thermocouples at known distances from the surface and the rate of heating was detd. below and above the decompn. temp. Expressions are developed for the rate of heating of flat slabs and spheres, with or without a consideration of radiation. The results cannot be given in an abstract. W. L. BADGER

The applications of filter devices for protection against gases in mines. MEUSS. *Z. ges. Schiess-Sprengstoffw.* 23, 206-9 (1928).—A discussion of the advantages and limitations of the canister type of gas mask as compared with the O helmet. J. S. REICHERT

Use of woolen fabrics for filtration. P. I. SOKOLOV AND V. P. DREVING. *J. Chem. Ind. (Moscow)* 4, 232-5 (1927).—An investigation was made by S. and D. of comparative resistance of various woolen cloths when used in filtering acid liquids at various temps. After use, the tearing strength of the cloths was tested by means of Schopper's app. The temp. at which the liquids are being filtered has a paramount influence on the extent of the damage suffered by the cloth. Some of the cloths suffered considerable loss of weight and of strength by the action of water alone above 50° . As a rule, at 45° a 10% H_2SO_4 soln. weakens a woolen cloth to the same extent as pure water does at 60° ; at 60° the 10% H_2SO_4 soln. effects a profound damage on the fabric, and at 80° it practically renders it unfit for use. Although all fabrics used were made of pure wool, some of them have shown a considerably better resistance than others. A soft cloth was weakened more than a hard one on being subjected to the action of acid liquids under the same conditions. HERNARD NELSON

Recent progress in the refrigeration industry. R. BILLARDON. *Tech. moderne* [20], 12, 409-17 (1928).—B. reviews the mech. and thermodynamical progress accomplished in the last few years (*Tech. moderne* [16], 17, 565 and [16], 18, 604), in the compressors used for refrigeration. P. THOMASSET

Injury of vegetation caused by factory fumes—methods of chemical analysis. G. VERPLANCKE. *Ann. Gembloux* 33, 333-62(1927); *Expt. Sta. Record* 58, 511.—The symptoms of toxication by industrial fumes and the relative sensitiveness of various plants are discussed at some length; analytical methods, based upon familiar procedures, are given for the detn. of SO_2 in air and of various substances likely to be present in plants as the result of exposure to toxic industrial fumes. H. G.

The diagnosis of lead poisoning. OTTO STRICKL. *Arch. Hyg.* 98, 43-58(1927).—Long-continued exposure of the employees of a Pb smelter to poisoning by Pb produced a variety of effects upon various organs, upon the central nervous system, and especially upon the blood cells. The no. and intensity of the symptoms depend to some extent upon the previous history of the subject. P. Y. JACKSON

A critical examination of the blood in lead poisoning, with special attention to the various methods of preparing the polychromatophiles and the basophilic erythrocytes. H. BRÜCKNER AND R. SPATZ. *Arch. Hyg.* 97, 277-98(1927).—The no. of polychromatophiles and basophilic erythrocytes found in the blood of a guinea pig or dog suffering from Pb poisoning is not only not const., but varies widely according to the method of staining. The technic of staining is discussed. P. Y. JACKSON

Compositions for producing oxygen. DEUTSCHE GOLD- UND SILBER SCHEIDANSTALT VORM. ROESSLER. Brit 280,554, Nov. 10, 1926. O-evolving compns. suitable for use in respirators comprise Na peroxide or other alkali metal peroxide with a catalyst such as O compds. of Fe or Mn, hydrated while cooling and stirring with water in finely divided condition.

Gas-diffusing unit. ERNEST J. SWEETLAND. U. S. 1,677,502, July 17. A porous block which may be formed of wood has its pores treated with (but not obstructed by) a preservative material such as shellac, linseed oil or creosote and may be used for app. for sewage aeration, ore flotation, etc.

Dispersing noxious gases. WINFORD L. LEWIS. U. S. 1,675,940, July 3. SnCl_4 and an aq. NH_3 soln. which may also contain NH_4Cl are brought together in order to disseminate chloropicrin or other substances. An app. is described.

Reflux system and apparatus for fractional condensation of vapors from coal tar or other mixed vapors. LOUIS WEISBERG (to The Barrett Co.). U. S. 1,676,232, July 3.

Treating liquids with gases in a succession of reaction vessels. A. F. MEYERHOFER. Brit. 274,881, July 24, 1926. An app. is described for carrying out processes as described in Brit. 269,491. The liquids or the gases are passed successively through a series of vessels and the liquid and gas may pass in counter current.

Crystallizing paraffin or other substances from solution. ALBERT DELAS (to Soc. des condenseurs Delas). U. S. 1,677,551, July 17. A volatile substance, e. g., water, is intimately incorporated with a soln. such as oil contg. paraffin, and cooling of the soln. to effect crystn. is effected by vaporizing the volatile substance.

Emulsions. W. E. BILLINGHAM. Brit. 280,762, May 25, 1926. Emulsions of oils, fats or waxes in concd. form are prepd. by treating liquid rosin or the like with alkali to produce a soap contg. 39% rosin, agitating with the material to be emulsified and then mixing with casein or similar protein material.

Refrigerating system. PIERRE E. HAYNES. U. S. 1,765,455, July 3. An app. is described in which ether and CO_2 may be used as the refrigerating medium.

Refrigerating system. FRANK W. SCHWINN. U. S. 1,676,837, July 10.

Refrigerating apparatus of the absorption type. GAUDENZ BAYER. U. S. 1,676,068, July 3.

Refrigerating system of the absorption type. BALTZAR C. VON PLATEN and CARL G. MUNTZERS (to Electrolux Servel Corp.). U. S. 1,675,474, July 3.

Compression refrigerating apparatus. G. ZWICKY. Brit. 280,577, Nov. 15, 1926.

Gas scrubber for refrigerating apparatus. ALLAN C. THAYER (to Ubald R. Loranger). U. S. 1,677,804, July 17.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Chemical composition of the thermal waters of Barèges. R. MASSY AND P. CAZAUX. *J. pharm. chim.* 7, 340-5(1928).—Results obtained by M. and C. (12^e Congrès internat. d'Hydrol., de Climatol. et de Géologie médicales, Lyon, Oct. 1927) differ from those of Robine and Dejussieu (*C. A.* 22, 1816) notably in regard to total S. A joint study is proposed in order to establish, in the interest of reliable therapy, whether these waters have const. or variable characters.

The artesian wells at Gyömrő (Kom. Pest) [Hungary]. HEINRICH HORUSITZKY. *Földtani Közlöny* 56, 218-20(1927).—The various deposits crossed by the wells are enumerated, and an analysis of the water is given.

The water of the laguna of Puan. CARLOS A. GRAU. *Anales oficina quim. provincia (La Plata)* 1, 23-37(1927).—An examn. was made of the H₂O in the laguna of Puan because in the province of Buenos Aires the H₂O in a number of the lagunas has a medicinal value. The therapeutic action of the H₂O must be associated with the mineral content since the H₂O is only slightly radioactive. Several very complete tables of analyses are given.

Determination of the iodine content of drinking water. HERMANN SCHRÖDER, J. F. RIETH AND S. N. BLUMSTEIN. *Chem.-Ztg.* 52, 440(1928).—Drawe (*C. A.* 22, 1419) published a method for detg. the I content of water which has brought forth vigorous independent letters of protest from the above 3 scientists, all of whom point out that the method of D. is not sensitive enough to detect I⁻ in the low concns. which are likely to be present in drinking water.

Report on municipal sanitary engineering practice in Great Britain. H. W. STREETER. *U. S. Pub. Health Service, Pub. Health Bull.* No. 166, 1-56(1927).—Sanitary administration in Great Britain is compared and contrasted with that in the United States. In general, filtration processes in Great Britain occupy a place secondary to long-time storage for water treatment. Where filtration is used, the slow-sand method is followed to a large extent in preference to the rapid-sand method, the latter being depended upon mainly as a roughing treatment prior to slow-sand filtration. Chlorination of water is beginning to be utilized extensively, but chem. coagulation is practically unused in Great Britain. Other features of British practice in water supply discussed are: (a) the many types of pumps, (b) the increasing use of metal pipe lined with bitumen or concrete mortar by the "spinning" process, (c) the use of sodium silicate at Birmingham, as an anticorrosion treatment for stored water, and (d) the use of rapid-sand filters, without a coagulant, for the removal of microorganisms. Recent progress in the application of the activated-sludge process of sewage treatment is described, especially the successful developments in methods of aerating sewage directly from the atm., by means of mechanical agitation and surface contact. Other features are: (a) the use of large detritus tanks for the preliminary removal of coarser suspended matters, (b) the high efficiency of revolving and traveling distributors as used in connection with percolating sewage filters, (c) the use of partial activated sludge treatment at Birmingham as a measure for increasing the capacity of a large existing percolating filter installation, (d) the methods pursued in the sep. digestion of sludge, and (e) the effective measures taken to make sewage treatment works and their surroundings attractive in appearance. For refuse disposal, large-scale application is being made at Birmingham, Sheffield, and other cities, of the incineration method combined with that of sepn. Other interesting features of British practice in refuse disposal were: (a) the apparently universal custom of combining garbage and rubbish at the dwelling for collection and disposal, (b) the ingenious uses made of power generated by incinerating refuse, and (c) the increasing sentiment against the "tipping," or "dumping" of crude refuse on land. An appendix describes the bioaeration method of sewage treatment at Sheffield.

Additional water supply for Manila. P. I. PAUL W. MACK. *Eng. News-Rec.* 100, 841-2(1928).—The history of the water supply of Manila is reviewed and the present supply from the Montalban River is described. A new supply from the Angat River is being developed and a 40-million-gals.-per-day rapid sand filter plant is under construction. The av. consumption is 23 million gals. per day.

Raw-water chlorination at Sandusky. O. F. SCHROEPFLE. *Seventh Ann. Rept. Ohio Conference on Water Purification* 1927, 19-21.—Brief additional data (cf. *C. A.* 22, 471) are presented regarding prechlorination at Sandusky, O., as a means of producing a filter effluent conforming to the U. S. P. H. S. standard. The process is very

effective except during the period when the water temp. is around 0°. At such times the bactericidal efficiencies are lower because the amt. of Cl₂ which can be applied and still maintain absence of free Cl₂ in the filter influent is materially less. The presence of free Cl₂ in the filter influent during the winter period resulted in low efficiencies due to unloading. This does not occur when the temp. is higher. The av. *B. coli* index of the filtered water during the whole prechlorination period was 1.44 per 100 cc. By maintaining free Cl₂ in the influent throughout the year it is hoped to avoid unloading during the winter.

R. E. THOMPSON

Raw-water chlorination at Warren. PHILIP J. O'CONNOR. *Seventh Ann. Rept. Ohio Conference on Water Purification 1927*, 21-4.—Prechlorination has been experimented with as a means of coping with the increasing pollution of the Mahoning River water. The plant is of 8-million gals.-per-day capacity, the present consumption being 3 million gals. per day. The Cl₂ is applied before the water enters the mixing chambers. The bacterial content of the water entering the settling basins was much lower than that of the raw water, but a great increase occurred in the coagulation basins, the bacterial count of the filter influent being at times higher than that of the raw water. The *B. coli* content, however, was consistently reduced throughout the treatment, the filter effluent at all times conforming to the U. S. P. H. S. standard. Secondary Cl₂ treatment of the filter effluent rendered the water practically sterile. The treatment eliminated algae growths in the basins and increased the length of filter runs during the summer months.

R. E. THOMPSON

Raw-water chlorination at Akron. J. S. GETTRUST. *Seventh Ann. Rept. Ohio Conference on Water Purification 1927*, 24-7. Prechlorination was exptd. with at Akron during February and March, 1927, in an effort to eliminate the gas-forming organisms previously reported (cf. *C. A.* 21, 145; 22, 651). These organisms, which ferment lactose only after 24 hrs. incubation, occurred in 50% of the 10 cc. samples of chlorinated water examd. during 1925. Cl₂ in amts. up to 2.23 p. p. m. was applied to the water entering the mixing chambers and SO₂ was applied at the outlet of the coagulation basin to remove the residual Cl₂, which was as high as 1 p. p. m., the contact period thus provided being 5 hrs. The treatment effected a considerable reduction in the bacterial content of the filter influent and *B. coli* was removed entirely, but it was not effective in reducing the gas-forming organisms mentioned. The bacterial quality of the delivered water was not materially changed. No benefits were observed which would recommend chlorination of the raw water as a regular practice. In discussion, G. R. Patton reported that prechlorination was employed at Struthers for removal of taste due to algae. Treatment of the water with 0.6-0.8 p. p. m. Cl₂ in a preliminary sedimentation basin providing approx. 3 days detention has completely eliminated taste troubles.

R. E. THOMPSON

Report of the water-softening and purification works for 1927, Columbus, Ohio. CHARLES P. HOOVER. *The City Bull.*, Columbus, O. *Ann. Rept. 1927*, 27-35; cf. *C. A.* 22, 1816. The per capita consumption of water was 9.8 gals. per day. Hardness was reduced from 230 p. p. m. to 87. The cost of CaO, soda-lime and Cl per million gals. treated was \$14. Carbonation effectively reduced the phenol alkyl from 33 p. p. m. to 7. The only difficulty in operating the carbonation plant was due to the corrosive action of the gases on the valve seats of the air compressor used to force the washed gases through the diffusers. Full details are found in 12 tables.

CARL R. FELLERS

Mechanical control of wash-water application at Bellaire. *Seventh Ann. Rept. Ohio Conference on Water Purification 1927*, 27-9. An illustrated description of a device developed by E. J. Lewis for automatically controlling the application of wash water through a hydraulic valve at the Bellaire, O., filter plant. The device causes the valve to open and close slowly, preventing overturning of the filtering material, and controls the length of wash to any predetd. period.

R. E. THOMPSON

Description and operating results of the Barberton water-purification plant. H. T. CAMPION. *Seventh Ann. Rept. Ohio Conference on Water Purification 1927*, 47-50. The 4-million gals.-per-day filter plant put in service at Barberton in June, 1926, treating water from an impounding reservoir on Wolf Creek, consists of nozzle aerators, mechanical mixing basins, coagulation basins, 4 rapid sand filters and chlorinating equipment. Prechlorination has been found effective in increasing the length of filter runs during the summer months when algae are numerous. Mn, up to 1.25 p. p. m. derived from decaying vegetation in the new reservoir, has placed an additional burden on the filter plant. Total Mn was detd. by the persulfate method and Mn⁺⁺⁺ by its reaction with *o*-tolidine reagent. The proportion of Mn⁺⁺⁺ was extremely irregular. Oxidation continued in samples standing in the lab., being complete in 3-5 days, i. e.,

when p_H reached 8.0 in consequence of loss of CO_2 . Addn. of $CuSO_4$ prevented oxidation, presumably by killing the organisms effecting the change. Cl_2 in amts. up to 10 p. p. m failed to oxidize the Mn. H_2O_2 effected complete oxidation, the reaction being hastened by raising the p_H with lime. This method was employed in detg. total Mn with *o*-tolidine. Lime treatment followed by coagulation with alum or $FeSO_4$ will ppt the Mn. With sufficient lime to render the water caustic all the ppt. settles in the basins, but with lower amts. of lime some of the floc is carried on to the filters, and, with the accompanying growths of slime and Mn bacteria, cements the filter sand causing short runs. Raw-water chlorination will prevent these growths to a large extent, allowing longer runs. The Mn is very difficult to remove from the filters. A tremendous increase in the nitrite content occurs during filtration. The significance of this is not apparent.

R. E. THOMPSON

Description and operating results of the water purification and softening plant at Piqua. J. M. MONTGOMERY. *Seventh Ann. Rept. Ohio Conference on Water Purification 1927*, 38-46. The 5-million-gals-per-day purification and softening plant at Piqua, treating water from Swift Run Lake, consists of nozzle aerators, mechanical mixing tanks, a Dorr clarifier, settling basins, carbonation chambers, coke burner and scrubber, 4 rapid sand filters and chlorination equipment. Alum and lime are applied to the water entering the mixing chambers. Sludge removal by the Dorr clarifier has averaged 97%, 0.75% of the water entering the plant being wasted in removing the sludge. In softening as ordinarily practiced, the theoretical limit of 17 p. p. m. of carbonate hardness cannot be nearly attained, probably because of the formation of basic Mg salts. At Piqua it has been found that excess lime treatment can be effectively employed to increase softening efficiencies. Sufficient lime is added to produce a caustic alk. of 40 p. p. m., which ppts the Mg as $Mg(OH)_2$. After settlement, the water is recarbonated until the total alk. minus twice the phenolphthalein alk. equals approx. 5. After filtration the water has a total alk. of 20-25 p. p. m., consisting of 15-20 p. p. m. normal carbonates and 5 p. p. m. of bicarbonates. The total hardness is reduced from 260 to 50-55 p. p. m. without the use of Na_2CO_3 . With ordinary lime treatment the total hardness would be 80-85 p. p. m. This additional softening is effected at a cost of 2.5¢ per p. p. m. per million gals. compared with 4¢ for ordinary lime treatment. The cost of Na_2CO_3 treatment would be 12¢ per p. p. m. per million gals. The CO_2 used is approx. the same as in ordinary lime treatment, only a sufficient amt. being added to convert caustic alk. to normal carbonate alk., whereas the usual method is to convert caustic and carbonate alk. to bicarbonates.

R. E. THOMPSON

Discussion of operating results of the new Piqua water-softening works. CHAS. P. HOOVER. *Seventh Ann. Rept. Ohio Conference on Water Purification 1927*, 64-5.—The results with excess lime treatment at Piqua (cf. preceding abstract) are discussed and the history of recarbonation is reviewed briefly. At Columbus during times of flood, when an excess of lime is required, the water is toxic to goldfish. This has always been assumed to be due to the excess lime added, but recent observations and expts. have led to the conclusion that the trouble is due to residual alumina in the water at times when the excess lime is employed. It is proposed to carbonate the water after settlement to reduce the p_H to the point where complete pptn. of the alum will be assured. It is believed to be better practice in treatment of flood water to add alum first, and then follow with lime-soda treatment after the bulk of the pptd. alumina and entangled mud has settled out.

R. E. THOMPSON

The manganese removal problem at Barborton. R. D. SCOTT. *Seventh Ann. Rept. Ohio Conference on Water Purification 1927*, 66. Brief data are given regarding the Mn content of some of the raw-water supplies in Ohio, together with data on the total and Mn incrustation of filter sand at several plants. Zeolite filtration offers a possible means of Mn removal.

R. E. THOMPSON

Final report on double coagulation studies at Cincinnati. CLARENCE BAHLMAN AND E. B. EVANS. *Seventh Ann. Rept. Ohio Conference on Water Purification 1927*, 60-3; cf. C. A. 22, 470. Final report is made upon double coagulation at the Cincinnati filter plant over a period of 16 months. Use of alum as the primary coagulant has been found more satisfactory than $FeSO_4$ treatment of equal cost. The saving in secondary chemicals, $FeSO_4$ and lime, has not equaled the cost of the more expensive primary coagulant. The additional cost of double coagulation has averaged 86¢ per million gals. Filter runs have been increased an av. of 31%, and wash water reduced 18%. This effect was confined solely to the warm-weather period, during which time the increase in length of filter runs was 30-65% and the wash water reduction 25-40%. Double coagulation has materially improved the quality of the

filtered water, and has enabled the uniform production of a chlorinated water of standard quality, even with extreme raw-water pollution. The filter effluent is not of standard quality under normal operating conditions employing double coagulation, but if the lime dosage is increased to give 1-3 p. p. m. caustic alkali, a coli-free effluent results. This enabled chlorination to be discontinued during a period when phenol pollution was present, giving rise to taste with the Cl_2 .

R. E. THOMPSON

The effect of chlorine on the bacteria in water. M. DÜGGELE. *Mitt. Lebensm. Hyg.* 19, 126-37(1928).—Effects of amts. of Cl_2 of temp., of time of exposure, and of the addn. of small amts. of lactose peptone and algin substance, were studied. Water contg. a flocculent suspension of org. material must be filtered before chlorination. Water treated with amts. of Cl_2 up to 0.5 mg per l., showing a practical absence of bacteria, may develop on standing for a short time at room temp. a large amt. of molds exceeding in no. the original amt. of bacteria.

J. C. JURRJENS

Biological purification of water for brewing. M. STRELL. *Wochschr. Brau.* 44, 607-13(1928).—Microorganisms can be removed by filtration with a Berkefeld, or with larger volumes of water, with a sand filter. They can be destroyed by passing chlorine or ozonized air into the water or by electroosmosis. By the latter method 50-100 l. per hr. of water free from bacteria and salts can be obtained from water giving 400 g. of residue per cu. m. and having a hardness of 12.4° by means of a current of 30 kw.-hrs.

A. SCHULTZ

Experimental bacterial and chemical pollution of wells via ground water, and the factors involved. C. W. STILES, H. R. CROHURST and G. E. THOMSON. *U. S. Pub. Health Serv., Hyg. Lab. Bull.* 147, 168 pp.(1927); *Expt. Sta. Record* 58, 184—This is a progress report of these studies, including also a Report on the Geology and Ground Water Hydrology of the Experimental Area of the U. S. Public Health Service at Fort Caswell, N. C., by N. D. Stearns. In studies of the distance to which excretal pollution of soil will travel in sandy soil with slowly moving ground water, bacterial pollution with *Bacillus coli* was recovered from well water in 1213 samples taken under a most rigid technic at distances varying from 1 to 232 ft. away from the exptl. trench in which excretal pollution was placed. Chem. pollution was recovered from well water up to 450 ft. from the same trench. Both uranin and *B. coli* traveled in the direction of the ground water flow, and neither was found in other portions of the exptl. field. Wet weather, resulting in high ground water, was conducive to extension of the pollution, whereas dry weather, resulting in low ground water, was inhibitive of the extension and conducive to purification of the ground water. *B. coli* tends to localize in the upper blanket at or near the ground water table. When the ground water falls, *B. coli* tends to filter out into the capillary fringe or into the soil. If the soil remains dry sufficiently long *B. coli* dies. Uranin appeared to float out in a blanket at or parallel and close to the ground water table, and tended to filter out into the capillary fringe and soil. However, it did not seem always to rise with higher ground water. Experimental *B. coli* infection of the ground water had remained alive for 2 years and 8 months when last examined, while uranin remained visible in the ground water for 2 years and 7 months. The changes of the ground water elevations play an important part in the progression of the pollution, carrying the bacteria along to more distant points. As pollution traveled it did not appear to expand laterally but appeared to contract to narrower breadth. Under the circumstances it is considered obvious that circular cesspools have a mathematical advantage in this respect over square or oblong pits. A mathematical analysis of the spread of pollution, as indicated by these results, leads to the conclusion that distance from points of pollution represents the great factor of safety in water supplies.

H. G.

Spontaneous precipitation of salts in rivers receiving the residual liquids of the potash industry. EMMERLING. *Chem.-Ztg.* 52, 308-9(1928).—Considerable quantities of MgO are pptd. in the beds of certain rivers. This pptn. is due to residual liquids of the salt industry which contain a very fine suspension of clay and CaCO_3 . In the absence of the clay, the carbonate would not ppt. MgO . Humic acid present in these waters also plays an important role. The plants growing in the rivers, principally *Polamogelon pectinatus* and *Cladophora*, sep. an appreciable amt. of CaO and MgO .

A. L. HENNE

Industrial wastes affect plant water supply. D. C. CARMICHAEL. *Power Plant Engineering* 32, 711-4, 813-5(1928).—A study of a stream polluted with wastes from an iron mill. The effects on feed water for boilers and cooling water for condensers are noted. Treatment of plant water is outlined. Neutralization of acid wastes from iron mills with lime and recovery of FeSO_4 are suggested as methods to dispose of trouble.

S. D. POARCH

Sewage treatment at Groningen. H. BLUNK. *Gesundh. Ing.* 51, 380-2(1928).—Three possibilities exist for the disposal of the sewage of Groningen: (1) pumpage through a 28-km. pipe line to the Delfzijl, (2) pumpage into the heath at Drenthe, or (3) treatment near the city. In deciding which of the 3 is to be employed, consideration should be taken of the construction cost, operating cost, and the rights of the general public.

Water consumption and sewage discharge at Denver. S. T. WEILLER. *Eng. News-Rec.* 100, 556-60(1928).—The results are given of a detailed study of water consumption and sewage discharge at Denver. The data obtained indicate that the actual return of water used for strictly domestic and factory purposes to the river by way of the sanitary sewers is approx. 95%.

Change in p_H of fresh sewage solids. C. E. KEEFER. *Public Works* 59, 137 (1928).—Tests showed that the p_H of fresh Baltimore sewage, initially 6.8, dropped rapidly during the first 24 hrs. and reached 5.1 in 48 hrs. Conclusions are that fresh solids should be removed to digestion tanks as soon as possible and plans to provide one tank of the Baltimore plant with mechanical means for removal of fresh sludge are being prep'd.

Effect of chlorine treatment on the biochemical oxygen demand of sewage filter effluents. C. D. MCGUIRE. *The City Bull.*, Columbus, O. *Ann. Rept. Div. Sewage Disposal* 1927, 36-9.—Ten gal. samples were collected in earthenware pots. The immediate Cl demand was det'd. by the addn. of Cl water and titration of the sample directly with o-tolidine, with a spot-plate as an external indicator. Cl was added to the jar content in amt. equiv. to the immediate Cl demand in p. p. m. minus 0.2 p. p. m. The under-dosage was for the purpose of preventing sterilization of the sample. Biochem. O demand was det'd. daily for 5 days at 20°. For 45 detns. where the Cl demand was 2.32 p. p. m. the reduction in biochem. O demand at the end of 1, 2, 3 and 5 days was, resp., 65.5, 50.8, 42.1 and 41.5%.

Sewage treatment plant operation at Worcester. ROY S. LANPHEAR. *Water Works* 67, 69-72(1928).—Two years' operating results of this Imhoff tank-sprinkling filter plant having an av. flow of 22 m. g. d. are described. From 1.5 to 2.0 cu. ft. of screenings are removed per million gallons of sewage. Wire screens of 1-inch mesh are used across the Imhoff effluent channels to prevent clogging of the filter nozzles. Gas production in the Imhoff tanks was vigorous but gas is not utilized. Foaming has seldom occurred and never caused trouble. Because of trade-waste liquors the p_H of the sewage varies from 3.4 to 9.1.

Methods for computing the characteristics of sludge-digestion chambers. M. PRÜSS. *Gesundh. Ing.* 51, 401-6(1928).—The amount of the expected daily gas production *per capita* is dependent on two factors: (1) the amount of dry org. material *per capita* per day and (2) the time in which the sludge may digest. If all of the org. material could be gasified, the amount of gas obtained would be 30-35 l. *per capita* per day. However, the av. is only 20-24 l. The time of digestion and the per cent digestion are represented graphically in terms of other factors. A method by which the size of the digestion chamber can be est'd. from the water-content curve is described. The velocity of digestion increases rapidly with increasing temp., while the size of the sludge chamber decreases accordingly. The vol. of gas produced increases with increasing temp. Graphical plots of the calcd. results for a fresh sludge of 95% water content and for 6 temps. are given. From these, the size of the digestion chamber, daily gas production, etc., are estimated.

The economical importance of the utilization of gas from digesting sludge. M. PRÜSS. *Gesundh. Ing.* 51, 439-44(1928).—Several different types of mechanical construction for digestion chamber are considered and curves showing the daily gas production for artificially heated chambers are given. Artificial heating of the sludge to 25° without simultaneous mechanical mixing of the sludge in open chambers is possible only by the application of foreign external heat. Insulation of the chambers gives better results as less heat is lost in the winter months. Mechanical stirring also seems to give better results.

Sludge disposal at the Milwaukee activated-sludge plant. T. CHALKLEY HATTON. *Eng. News-Rec.* 100, 674(1928).—It is est'd. that the return from the sale of dried sludge in 1928 will be \$550,000 to \$600,000 and the operating expenses \$900,000, making the total cost of sewage disposal to the present metropolitan district 60-65¢ *per capita*. The production of dried sludge is approx. 100 tons per day, all of which is disposed of at a price exceeding the cost of production. A market has been built up which cannot possibly be met by the max. amt. produced.

Activated sludge plant for Wahiawa, Hawaii. F. M. VEATCH. *Eng. News-Rec.*

100, 478 80(1928) —A description of the activated sludge plant under construction at Wahiawa, a town of approx 3000 persons. As the flow of the stream into which the effluent will be discharged is very low, complete treatment is required. The plant was designed for treatment of an estd flow of 100 gals *per capita* per day from a population of 6000, and consists of 3 plain settling tanks, 6 aeration tanks, 2 final settling tanks equipped with Dorr clarifiers and a chlorination tank, the retention periods being 30 min., 6 hrs., 1.2 hrs. and 15 min., resp. The excess sludge will be digested in a tank with capacity equal to 2 cu ft *per capita*, and dried in glass covered beds ($\frac{2}{3}$ sq. ft. *per capita*) with forced ventilation. R. E. THOMPSON

Sludge heating and gas collection at Antigo, Wis. ANTHONY J. FISCHER AND FRANK K. QUIMBY. *Public Works* 59, 97-101, 135 7(1928). The Antigo plant was designed to treat 900,000 gallons of sewage per day from a population of 10,000 and includes a grit and screen chamber, a clarifying tank, a sep. sludge-digestion tank, sludge beds and filters. The digestion tank is equipped with a Dorr mechanism rotating at 1 1/2 r. p. m., a gas-collecting dome, hot water heating pipes and piping for circulating sludge or applying fresh sludge at the top or bottom. The gases evolved from the digesting sludge are utilized for heating the sludge. The gas collection and water-heating systems are automatic. The plant was put into operation in December without seeding. The sludge temp. was brought up to 66° F. during the first 2 weeks and no difficulty was experienced in maintaining that temp. Lime was added to adjust the p_H to 7.4 and it was necessary to circulate the sludge to prevent the accumulation of lime sludge. After the first 3 months the proper p_H was maintained in the digestion tank without liming and circulation was discontinued. Daily gas production is about 3500 cu. ft. or 0.64 cu. ft. *per capita*. A well-digested, ripe sludge is produced with an av. solids content of 8.9%, of which 57.5% is ash. C. C. RECHMORT

Mechanical aerator for activated sludge at Princeton, Ill. F. C. RORER. *Water Works* 59, 179-81(1928). The new Princeton plant with a capacity of 500,000 gal. per day includes grit and coarse screen chamber, a preliminary settling tank with 1-hr. detention period, 5 aeration units, using simplex mechanical aerators, having an 8-hr. detention period, a final settling tank and a pump house. An activated sludge was built up readily and increased to about 18% of the flow. The plant cost about \$51,000. C. C. RECHMORT

Sedimentation at separate sludge-digestion plants. ANTHONY J. FISCHER. *Public Works* 59, 176 9(1928). The results of 5 sedimentation plants of the same type are compared and showed uniformly high removal of solids that can be settled and considerable variation, from 52.3 to 78.2%, in removal of suspended solids. The av. flow of the plants was 86 gallons *per capita* and the suspended solids content of the raw sewage was 57.5 g. *per capita* per day. A reduction in the biochem. O demand of from 13 to 35% was obtained in these clarifiers. C. C. RECHMORT

Digestion of vegetable wastes and screenings in sewage treatment plants. WILHELM RUDOLFS AND H. HEIKELERIAN. *Water Works* 67, 113 6(1928). Expts. on the digestion of various mixts. of ripe sludge, fresh solids and vegetable wastes and of ripe sludge, fresh solids and screenings are described. Duplicates of each mixt. were set up and the reaction of the duplicates was adjusted to p_H 7.4 with lime. Liming increased the gas production in all mixts. with the exception of the screenings and ripe sludge mixt. Mixts. of screenings with ripe solids and with ripe and fresh solids digested very readily. The addn. of vegetable wastes to ripe and fresh solids hindered the digestion so that max. gas production was set back from 20 to 40 days. Mixts. of vegetable wastes and ripe solids did not digest satisfactorily, even with the addn. of considerable quantities of lime. C. C. RECHMORT

A study of factors affecting the efficiency and design of farm septic tanks. E. W. LEHMANN, R. C. KELLEHER AND A. M. BUSWELL, III. *Agr. Expt. Sta. Bull.* 304, 299 339(1928). Recommendations are made for the design, construction and operation of farm septic tanks, based on chem., bacterial and engineering exptl. studies. CARL R. FELLERS

Treatment of slaughterhouse waste in Holland. WILHELM RUDOLFS AND H. KESSENSE. *Public Works* 59, 151 4(1928). A small surface-aeration plant designed to treat 30,400 gallons of strong slaughterhouse waste daily is described. The aeration tank is equipped with submerged paddles rotating diagonally to the flow of the sewage at a speed of 3.75 r. p. m. to keep the sludge in suspension; and 4 nine foot long street-cleaning brushes submerged about 1/2 in. rotating 57 r. p. m. for aeration. Operating results indicate excellent purification. C. C. RECHMORT

Refuse disposal in Providence. DAVID L. BOUCHARD. *Public Works* 59, 127-30(1928).—Refuse and garbage are collected with trucks each equipped with two 1.25-

ton removable tanks, and are delivered to a Decarie two-unit incinerator, which is operated on two 9-hr. shifts each day.

C. C. RUCHHOFT

Effect of various chemicals on the spreading and penetration of oils in different mosquito breeding places. JOSEPH M. GINSBURG. N. J. Mosquito Exterm. Assocn., *Proc. 14th Ann. Meeting* 1927, 52-61.—The need for increasing the spreading power of oils and of increasing spread and toxicity of the cheaper fuel oils is emphasized. The mechanism of spread, as put forward by Harkins and by Langmuir, ascribes the spreading power to the presence of either active or polar groups such as OH, COOH, etc., or double bonds in the hydrocarbon chain. Such a double or triple bond acts similarly to a polar group (OH, etc.), and is attracted by H₂O and, hence, causes spreading. G. concludes that an oil contg. unsatd. hydrocarbons should spread more rapidly than an oil free from these hydrocarbons. Tests confirmed his theory. Varying percentages of 35 compds. were tested and greatest success was had with monohydric alcs., phenols, cresols, xlenols, pine oils and turpentine. Of these, the cresols proved best both as to spreading power and toxicity. With fuel oil as a testing medium, the most effective mixture was made by adding 1% cresylic acid. This spread 1½ times as much as plain fuel oil, penetrated among weeds and flottage, and killed larvae within 30 min. whereas pure kerosene took 12 hours. After kerosene, breeding was resumed in less than 3 days; after fuel oil with cresylic acid, no signs of breeding occurred after 3 days. The mixt. of 1% cresylic acid with fuel oil was tried with uniform success on pools, ditches, vegetation-covered ponds, cattail swamps, and salt marsh areas. It increased the cost of the oil less than 1 cent per gallon. The bibliography includes 17 references.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

Agricultural value of rainfall in the tropics. H. MARTIN LEAKE. *Proc. Roy. Soc. (London)*, B103, 82-96 (1928).—The effective rainfall is a daily measure of the soil moisture which originates in rain and is available for plant growth, and may also be used for the estn. of crop yields and of crop areas in a given tract. For agricultural plants, 2 curves may be drawn, giving the upper and lower limits of their water requirements at each stage of growth; the dual curve has a varietal significance. A bibliography is appended.

JOSEPH S. HEPBURN

Aqueous vapor pressure of soils. III. Soil structure as influenced by mechanical

treatments and soluble salts. M. D. THOMAS. Utah Agr. Expt. Sta. *Soil Science* 25, 409-18(1928); cf. C. A. 18, 2571.—Samples of Trenton clay were treated to simulate a thorough puddling and were also frozen, when the soil contained enough water to render it plastic, and the vapor pressure moisture relations of the materials were studied. Puddling the clay increased its water-absorbing power at vapor pressures above 85%. Freezing had the opposite effect. When the soil was dried further, these differences disappeared, but returned when the soil was moistened again. Calcd. by means of the thermodynamic capillary equation indicated that the smallest capillary spaces affected by these treatments had a size range from about 5 to 25 millimicrons radius. Addition of the chlorides of Na, Mg, Ca and Al modified the water-absorbing power of the soil by an amount which could be calcd. on the assumption that the salt was entirely in soln. and did not exert any influence on the soil. KCl appeared to be partially absorbed from the soil soln. but it may have reacted with the replaceable bases in the soil, giving a K silicate complex which has a lower water-absorbing power than the natural soil, thus indicating a reduction in the concn. of the soil soln. which did not occur. Sulfates and carbonates were pptd. by the soil and largely removed from the soil soln. There is some evidence of base replacement in these reactions. J. J. S.

Replaceable bases in some soils from arid and humid regions. M. D. THOMAS. Utah Agr. Expt. Sta. *Soil Science* 25, 379-92(1928).—Eight clays and a natural mineral colloid were treated to exchange their bases for a single base, and the process was followed by chem. analysis. When alkali soils were leached with water there was a nearly const. soly. of the Na on a high level of concn. as compared with the other bases, after the removal of sol. salts. The alkali soils contained appreciable amts. of sol. silicates which were not present in the humid soils. The arid soils showed a marked tendency to hydrolysis on washing out the sol. salt. The discrepancies between the amts. of bases dissolved and NH_4 absorbed by the Utah soils were accounted for. The arid soils had higher p_{H} values than the other soils. Drying at 110° changed the p_{H} values considerably. Chem. analyses of the colloid into which different bases had been introduced showed that the material is a hydrated Mg Al silicate in which about $1/3$ of the Mg is replaceable by other bases. This material has properties closely analogous to those of the soils. J. J. SKINNER

The relation of soil type to the exchangeable calcium and magnesium in some Illinois soils. M. P. CATHERWOOD AND E. E. DETURK. *J. Am. Soc. Agron.* 20, 657-78(1928).—This investigation was undertaken with a view to detg. the relation of the exchangeable Ca and Mg in soils to soil type differentiation. Four soil types were investigated. The types were described and the methods of analysis indicated. Part I presents data on the surface samples showing the relation between exchangeable Ca and Mg and soil type with respect to the following: (A) relation of exchangeable Ca and Mg to the apparent maturity of the soil, (B) total amts. of exchangeable and non-exchangeable Ca and Mg, (C) ratio of exchangeable Ca to exchangeable Mg, (D) the percentage of the total Ca and Mg which is exchangeable. Part II gives data and conclusions resulting from analysis of all the horizons of the same types with reference to these points. E. F. SNYDER

The relation of the concentration of calcium ion required by alfalfa to the amount present in soil solution. H. W. E. LARSON. Oregon Agr. Expt. Sta. *Soil Science* 25, 399-408(1928).—The min. concn. of Ca ion required by the alfalfa in water cultures to make growth appears to be about 16 p. p. m. The most economical growth was produced with about 32 p. p. m. Ca present in excessive concns. does not seem to be toxic to the plant; instead, increased growth may be produced. The presence of sufficient Ca ion in a soln. produces a strong, healthy plant with a stocky root system which when inoculated has a large number of nodules. In studies of the effect of season and treatment on water-sol. Ca content in soils, in field, and in pots it was found that the water-sol. Ca content of certain soils is found to be below the amt. necessary for a satisfactory growth of alfalfa in soln. culture. The application of ground limestone and S increases the water-sol. Ca content of the soils as used in this investigation. By the application of ground limestone, the water-sol. content of some soils can be increased and maintained throughout the season at a concn. which will eliminate Ca as the limiting factor in plant growth. The sol. Ca content of some soils seems to be lowest during the early part of the season, which is the time that the plant requires Ca in large amts. The amt. of replaceable Ca present on the ultra-clay complex varies during the season; also the application of limestone tends to increase the amount present. It is probable that Ca tends to conserve the base-absorbing capacity of the soil or prevent soil deterioration. J. J. SKINNER

Rapid colorimetric determination of phosphorus in soils and vegetation. IDA

LONSTEIN. *J. S. African Chem. Inst.* 10, 49-50(1927); cf. *C. A.* 21, 2161.—The unknown soln., neutralized with NH_4OH , is treated with 0.5 cc. of a soln. of 100 cc. 10% $(\text{NH}_4)_2\text{MoO}_4 + 300$ cc. 50% H_2SO_4 and dild. with H_2O to 19.8 cc. and 0.2 cc. of a soln. of 0.1 g. Sn in 2 cc. concd. HCl and one drop of dil. CuSO_4 , warmed and made up to 10 cc. The color of this soln. is compared after 5 min. with the color developed in a standard phosphate soln. $(\text{NaNH}_2\text{HPO}_4)$ equiv. to 0.1 mg. P_2O_5 . After transference to matching cylinders the amt. discarded from the darker to obtain the same tint in both is measured and the reading depth of the standard times 0.01 mg. divided by the reading depth of the unknown gives mg. of P_2O_5 in the aliquot. A. T. F.

The determination of nitrates in soil. R. P. BARTHOLOMEW. *Arkansas Agr. Expt. Sta. Soil Science* 25, 393-7(1928).—A study was made of the value of $\text{Al}_2(\text{SO}_4)_3$ and $\text{Ca}(\text{OH})_2$ as clarifying agents in the extn. of nitrite N from soils. Some observations were made of the rate of the transformation of nitrite to nitrate. $\text{Al}_2(\text{SO}_4)_3$ and $\text{Ca}(\text{OH})_2$ used in the soln. for the extn. of NO_2 from soil gave a clear ext. in a short time. All the N present in soils as NO_2 was extd. by this method. NO_2 was converted to NO , very rapidly in soil. The transformation is largely due to biol. reactions. J. J. S.

The action of neutral salts on acid soils with reference to aluminum and iron. SANTE MATTSO. *Bur. of Soils. Soil Science* 25, 345-50(1928).—Soil colloidal materials were given alternate treatments with 0.05 N HCl and 1.0 N neutral chloride solns. Al and Fe were dissolved in appreciable quantities only by the first few treatments with the acid soln., whereas with the chloride treatments considerable quantities of these elements were yielded continually each time the materials were rendered unsatd. by the preceding acid treatment. The reaction is due to the liberated acid, the activity of which was shown to be greatly increased by the high Cl-ion concn. of the salt. A mixt. of the acid and the salt solns. brought about a complete decompn. of the material. That the exchange acidity is independent of the presence of Al and Fe was shown in the case of specially treated soil colloidal materials. J. J. SKINNER

The effect of sulfur on soils and on crop yields. R. R. MCKIBBIN. *Md. Agr. Expt. Sta., Bull.* 296, 65-114(1928).—The amt. of H_2O -sol. S in a soil is no measure of the amt. of total S in that soil, and, conversely, a soil low in total S may be high in H_2O -sol. S. Soils low in total S readily oxidize elemental S to the SO_4 form. S behaves as a soil amendment rather than as a fertilizer. It helps to restore equil. in alk. soils by bringing the reaction of the soil soln. to neutrality just as lime helps to restore equil. in acid soils by bringing the reaction of the soil soln. to neutrality. The amount of H_2O -sol. P in a soil is governed by the reaction of the soil and not to any great extent by the total amt. of P present. S oxidation in most soils tends to make P less sol. rather than more sol. S and acid phosphate mixts. tend to lower yields of most crops grown in Maryland soils. S and pulverized raw rock phosphate mixts. tend to increase yields of most crops grown in Maryland soils. With Ca and with S there seems to be a very good balance maintained between total and water-sol. soil content. When there is a low total amt. there will be a relatively high H_2O -sol. content. This suggests that the soil soln. may be satd. with respect to the 2 constituents, Ca and sulfate-S, in the soils studied. S oxidation in these soils tends to make less H_2O -sol. Ca. The relatively low soly. of CaSO_4 may have something to do with this fact. Applications of elemental S greater than 100 lbs. per acre should not be made on Maryland soils. In light applications and for specific crops it is believed that increased yields may be obtained in many cases through the use of elemental S. Elemental S should not be used in acid phosphate mixts. Mixed with raw rock phosphate it increases the value of that material in most cases. C. R. FELLERS

The position of France in the production and the consumption of chemical fertilizers. LOUIS BRULÉ. *Sci. et ind.* 12, 90-3(1928). E. H.

Determination of the fertility of the soil. JULIUS STOKLASA. *Internat. Agr. Kultur-Wiss. Rundschau* 2, 627-37; *Chem. Zentr.* 1926, II, 2998; cf. *C. A.* 21, 1514.—The respiratory intensity of soils fertilized with inorg. and org. substances was investigated. The CO_2 evolved increased in all cases, especially when the soils were fertilized with lime. The greatest effect was obtained with stable manure. Without a fertilizer about 4 g. of CO_2 per sq. m. were evolved each 24 hrs., with NaNO_3 5.58 g., with urea 5.65 g., with lupine 5.03 g. and with stable manure (in all cases 80 kg. of N per hectare) 6.59 g. The increase in CO_2 production was attributed to the stimulated activity of autotrophic and heterotrophic processes. The importance of org. fertilizers is discussed. C. C. DAVIS

Dehydration due to the application of fertilizer. HERMANN KRANTZ, MEMMINGEN AND BADENHAUSEN. *Swabia. Centr. Bakt. Parasitenk. II Abt.* 73, 70-4(1928).—K. discusses the literature and gives a bibliography. JOHN T. MYERS

The chemical and physical behavior of certain synthetic fertilizer salts when mixed with limestone and dolomite. W. H. MACINTIRE AND K. B. SANDERS. *J. Am. Soc. Agron.* 20, 764-70(1928).—Air-dry mixts. of limestone and dolomite with each of 5 concd. synthetic ammoniates showed either no loss of NH_3 or the most meager quantities after standing for 36 days at room temp. When the same mixts were brought to a moisture content of 6% the NH_3 losses were nil in 2 cases and measurable in 3. The max. loss, however, was only $1/7$ of the analytical error permitted the fertilizer analyst. The absence of any material loss of NH_3 showed that no change in chem. soly. ensued when the limestone was added to the fertilizer salts. Natural dolomitic limestone was less reactive than limestone. The phys. condition of each concentrate was affected unfavorably by exposure to a circulating moist atm., and in 3 cases the salts were practically liquefied. This tendency was eliminated when the concentrates were mixed with either of the 2 limestones in the proportion of 1 of salt to 4 of limestone. In a greenhouse expt. a mixt. of 2 parts of nitrophoska and 1 of ground limestone remained for weeks in a granular and uncaeked condition. E. F. SNYDER.

The influence of large doses of lime on the root solubility of potash and phosphoric acid fertilizers in the soil. S. GERICKE. *Fortschr. d. Landwirtschaft* 1, 774-7(1926); *Chem. Zentr.* 1927, I, 790-1; cf. *C. A.* 22, 1175. A preliminary communication. The influence of fertilization with CaO and CaCO_3 on the absorption of P and K by the germinating plants according to Neubauer and Schneider was studied. The lime requirements of marsh land and high land are given. Twenty-five g. of soil were treated for 2 days with frequent shaking with satd. aq. Ca(OH)_2 and the absorption was detd. by analyzing the supernatant liquid. The p_n of the CaO series was 8.0-8.8; that of the CaCO_3 series was 7.0-7.5. The influence of this fertilization on the root soly. of P and K varies. On high land the K_2O absorption increased, whereas on marsh land it diminished. The P_2O_5 absorption increased in some cases, and in others it diminished. The poorer a soil was in root sol. P_2O_5 , the more favorable was fertilization with lime toward the absorption of P_2O_5 . C. C. DAVIS.

The content of root-soluble phosphoric acid in soils according to Neubauer, and the results of field fertilization experiments. D. MEYER AND K. WODARZ. *Z. Pflanzener. nähr. Dungung Abt. B* 5, 433-42; *Chem. Zentr.* 1926, II, 3001. The content of root sol. P_2O_5 was detd. by the method of Neubauer and Schneider, and results were compared with results on the same soils in field expts. with cereals and vegetables. Soils with low Neubauer nos. required fertilizers in the majority of cases, whereas those with high Neubauer nos. in no cases required such treatment. With medium values, the results of the field expts. varied. When the vegetables were treated with stable manure, the effect of P_2O_5 was no longer so evident. Limiting values could not, however, be established, because the effect of P_2O_5 depended upon the condition of the soil, the P requirements of the plants, the weather and the form of fertilizer. C. C. DAVIS.

Some effects of method of application of fertilizers on corn in soils. F. B. SMITH. Iowa Agr. Expt. Sta., Ames, Iowa. *Res. Bull.* 104, 67-104(1927). A fertilizer contg. 2% NH_3 , 12% P_2O_5 and 2% K_2O and one contg. 0% NH_3 , 12% P_2O_5 and 2% K_2O had a greater effect on the development of both primary and secondary roots of corn than did one contg. 12% P_2O_5 . Germination and root growth of corn were retarded when the fertilizer was applied in contact with the seed. The greatest development of primary and secondary roots was secured when the fertilizers were applied in the hill, and thoroughly mixed with the soil. A fertilizer contg. 2% NH_3 , 12% P_2O_5 , and 2% K_2O and one contg. 0% NH_3 , 12% P_2O_5 and 2% K_2O applied in the hill mixed with the soil decreased the production of NO_3 and lowered the nitrifying power of the soil for 2 weeks after the fertilizers were applied. The retardation in germination of corn was not due entirely to the osmotic pressure of the salt soln. The elongation of cells and the rate of cell division were retarded by certain fertilizers independently of the osmotic pressure. J. J. SKINNER.

Tests of American soil-inoculating materials. FR. ZUCKER. Univ. of Leipzig. *Centr. Bakt. Parasitenk. II Abt.* 73, 499-509(1928). The effect on the soil bacterial flora of 17 com. fertilizers was studied. The manufacturers' claims as to marked effects of microbiological activity were greatly exaggerated. Some of them had fertilizer value but the cost was too high. Many preps. of N-fixing bacteria are inert. Only those approved by competent scientists should be purchased by agriculturists.

JOHN T. MYERS.

The relation between the concentration of mineral elements in a culture medium and the absorption and utilization of those elements by plants. F. W. PARKER AND W. H. PIERCE. Alabama Polytechnic Inst. *Soil Science* 25, 337-43(1928).—An expt. is reported in which corn was grown in large vols. of culture soln., the P content

of which ranged from 0.05 p. p. m. to 0.50 p. p. m. PO_4 . The results indicate that corn will make max. growth at a concn. of 0.10 p. p. m. PO_4 if that concn. can be maintained throughout the growing period. In a second expt. corn and soy beans were grown in culture solns. which varied in K concn. from 0.5 p. p. m. to 25 p. p. m. K. The results obtained show that both crops will make max growth at a concn. of 2.0 p. p. m. K or possibly less. The bearing of these data on the question of the nutrition of plants growing in soils is discussed. The results are taken to indicate that in many soils the displaced soil soln. is adequate for the K nutrition of plants but that in many soils, root-soil contact is necessary for the P nutrition of plants. J. J. SKINNER

Effect of spraying with fungicides on the keeping quality of Florida citrus fruits. H. R. FULTON AND J. J. BOWMAN. *U. S. Dept. Agr. Circ.* 409, 1-13 (1927); *Phytol. Abstracts* 12, 659.—The results of trials extending over 6 seasons show that citrus fruit grown in Florida can be improved in keeping quality by spraying with 3-3-50 Bordeaux mixt. plus 1% of oil in the form of emulsion. H. G.

Tar-oil wash trials in the west midlands, 1926-7. S. G. JARY. *J. Ministry Agr.* 34, 1107-13 (1928); cf. *C. A.* 21, 793.—Since the no. of aphids and apple suckers were small on the control trees, the relative merits of the washes were difficult to det. Mortegg, Battle's Winter Wash and Tarolite all appear to control these insects quite effectively. None of the washes gave more than a partial control of winter moth caterpillars. Results obtained on the control of capsid bug may be very deceptive. The distribution of this insect, even over a small area, may be very irregular, and unless precautions are taken to allow for this, one may easily arrive at wrong conclusions as to the value of any particular wash. The covering power of dinitroresol washes was equal to that of any of the tar-distillate washes. Dinitroresol washes leave marked stains on the clothes and skin, but do not leave a residue which clogs the spraying machinery. The trees were in no way harmed by any wash, and the strengths used may be regarded as safe when applied on plums and damsons before the end of Jan. and on apples before the end of Feb. E. F. SNYDER

Studies on toxicity of fluorine compounds. S. MARCOVITCH. *Tenn. Agr. Expt. Sta., Bull.* 139, 1-48 (1928); cf. *C. A.* 22, 2025.—The fluosilicates appear to be the best available substitutes for the arsenicals as agents for the protection of plants against phytophagous insects. As the white rat is a standard for pharmacol. studies, so the mosquito may be employed for insect toxicology. For insects and lower organisms, Na_2SiF_6 is more toxic than Na_3AsO_3 . Since F seems to effect the pptn of essential Ca from the tissues, the meager Ca content of the lower organisms may account for their susceptibility to F compds. By the aid of the formula $K = (1/t)\log(1/\text{concn.})$, a numerical toxicity value of 34.5 was obtained for Na_2SiF_6 , 15.1 for Na_3AsO_3 , 4.8 for Na_3AsO_4 , and 4 for NaF. On the other hand, to man and the higher animals the arsenicals are at least 9 times more toxic than Na_2SiF_6 , and 30 times more toxic than NaF. Dry dusts of Na_2SiF_6 and S were found to be more effective than dusts in the presence of moisture against adult bean beetles. The F compds are protoplasmic poisons, and their systemic action seems to be produced by the withdrawal from the tissues of Ca, the element that is essential for proper permeability, and its pptn. as CaF_2 . F compds. do not seem to be repellent to insects, and usually are more effective than arsenicals, especially with the cutworm (*Pontia duces*). On the other hand, for higher animals, such as birds and mammals, F compds. are distasteful in poison baits. Plants tolerate sol. fluosilicates better than sol. arsenicals. Free moisture seems to be the principal agency responsible for foliage injury by fluosilicates. In the presence of moisture $\text{Ca}(\text{OH})_2$, when used as a carrier for Na_2SiF_6 , may be the cause of foliage injury. S or flour was found to be safer than lime as a carrier, when used at the rate of 2 parts to 1 of Na_2SiF_6 . In the presence of moisture, $\text{Ca}(\text{OH})_2$ alone is capable of causing foliage injury on cucumbers. For quant. toxicological tests mosquito larvae were found to be well suited. The insol. fluorides of Ca, Mg and Sr show a low order of toxicity. Of the org. acids, salicylic was the most toxic, followed by oxalic, formic, benzoic and acetic. Of the metals, Hg was the most toxic. Ba, Pb, Zn and Cu showed some toxicity, although it was small in comparison with that of F. The arsenicals and F compds. are much more effective under high temps., especially above 39° . The fluosilicates possess marked antiseptic properties, and are highly toxic to protozoa. A 1-10,000 soln. of Na_2SiF_6 is almost instantaneously fatal to *Paramecium caudatum*. NaF (1-1000) required 60 min. for a lethal effect, while the same strength of sodium arsenite was harmless. Against the earthworm (*Lumbricus terrestris*) a 1-10,000 soln. of Na_2SiF_6 was fatal within 25 min.; thymol, 55 min.; KCN 5 hrs. C. R. F.

Analysis of insecticides: naphthalene; naphthalene and camphor; strychnine-base blue powders; red wheat. MAURICE FRANÇOIS AND (MISS) LAURE SEGUIN. *Ann.*

fals. 21, 204-9; *J. pharm. chim.* 7, 331-40(1928); cf. *C. A.* 21, 2353.—Naphthalene, when mixed with inert substances to disguise its identity, is generally the only sublimable compd. in the mixt. It is first sepd. by sublimation and then subjected to the usual identifying tests (microscopical examn., forms with picric acid a yellow cryst. compd. m. 149°, m. p. 79°, b. p. 220°). In naphthalene-camphor mixts. if natural camphor is used it can be detd. polarimetrically. If inactive camphor is used, it can be sepd. by means of β -naphthol, as follows: triturate 10 g. of the dry powder in a mortar with 5 g. β -naphthol, let stand 1 hr. (not longer), transfer to a tared Gooch crucible, apply suction till all the liquid has been drained off, change the suction flask, wash the naphthalene with 50 cc. of 5% NaOH, then with water, dry at atm. temp. and weigh. To the camphor-naphthol mixt. add 50 cc. of NaOH soln. and then the washings from the naphthalene detn., filter on a tared Gooch crucible, wash with H_2O , dry at atm. temp. and weigh the camphor. Blue powders for the destruction of moles contain strychnine sulfate, together with a relatively large amt. of methylene blue which interferes with the strychnine detn. The dye can be eliminated by addn. of KI to form insol. tetramethylthionine hydriodide, as follows: slowly percolate 30 cc. H_2O through 10 g. of sample on a small filter, add 15 g. KI and agitate to accelerate soln., filter immediately; the last traces of methylene blue can be removed by adding a few silk threads and allowing to stand 24 hr., and strychnine is then detd. by known methods. Mice poisons generally consist of mixts of cereal grains and strychnine sulfate colored a deep red (generally with eosin). Though the alkaloid does not penetrate inside the grain, it cannot be removed by distd. H_2O , and is best extd. by treating the unground product with cold 1% H_2SO_4 for 24 hrs. It is then detd. in the soln. by known methods.

A. PAPINEAU-COUTURE

Surface tension of disinfecting solutions for American foulbrood. C. H. GILBERT. *Wyo. Agr. Expt. Sta. Bull.* 159, 119-31(1928).—The success of an immersion treatment of diseased combs lies in the ability of the soln. to penetrate into the cells and openings of the comb. CH_2O and EtOH mixts. have been widely used for this purpose, the former acting as a disinfecting agent and the latter as a penetrating agent. The surface tension of numerous soap solns., H_2O - CH_2O mixts. and gasoline was detd. by means of the *du Nouy tensiometer*. Pure soaps reduced greatly the surface tension of soft H_2O in very high dilns., i. e., 1 lb. soap flakes to 40 gals. of H_2O . Temp. had very little effect on the surface tension of the disinfecting soln. Soap solns. should be used alone, not mixed with CH_2O , because their penetrating is lost after a single 48 hr. immersion. The soap soln. dissolved from 3.7 to 10% of the wax in combs in 24 hr. while a 48 hr. treatment caused a wax loss of from 11 to 15%. C. R. F.

The use of calcium cyanide in the apiary. C. L. CORKINS. *Wyo. Agr. Expt. Sta. Bull.* 158, 109-16(1928).—For killing instantly all bees in foulbrood-infected hives, $Ca(CN)_2$ proved superior to CH_2O or S fumigation. The cyanide treatment does not poison the honey, which can be recovered. $Ca(CN)_2$ proved very effective in destroying ants in hills or mounds. $Ca(CN)_2$ was superior to CS_2 or p - Cl_2H_2Cl when used to fumigate hives or combs infected with wax moth. C. R. FELLERS

The danger to stock of poison baits for grasshoppers. H. R. SEDDON. *Agr. Gaz. N. S. Wales* 39, 64 6(1928).—Na arsenite and Paris green in doses of 20 grains were fatal to sheep but does of 6.6 grains had no ill effects. Sheep did not voluntarily eat Na arsenite baits but Paris green baits were eaten in some instances by starved animals. Results of the expts. indicated that poison grasshopper baits contg. Na arsenite or Paris green will not be toxic to sheep when broadcasted on pasture at the rate of 100 lbs. of bait per acre. The bait should not be spread in pellet or mass form, nor applied to bare soil, and stock should be kept off the baited areas for 1 to 2 days. Na arsenite appears to be much more toxic to sheep in hot weather than in moderate and cold weather. K. D. JACOB

Dipping of lambs. E. A. ELLIOTT. *Agr. Gaz. N. S. Wales* 39, 106(1928); cf. *C. A.* 21, 1865.—The growth of lambs was not checked by dipping in As and C_6H_5OH solns. of the type and concn. ordinarily used for control of ticks and lice. Examn. of the lambs 4 weeks after treatment showed that the wool of the dipped animals was somewhat brighter than that of the controls but the wool of those dipped in As solns. had a slightly creamy tip. The skin of all the lambs was quite healthy. K. D. J.

Determination of the injury to seed by corrosives. GUSTAV GASNER. *Pflanzenkrankh. Pflanzenschutz* 36, 25-42(1926); *Chem. Zentr.* 1927, 1, 2860.—Germination expts. with wheat grains proved that injury by corrosives depends greatly upon the temp. of germination. Grain treated with $HCHO$ was injured at low temps., but treated with Hg preps. injury occurred at high temps. As a result, toxic doses cannot in general be established for low temps. Data on *toxic doses of formalin, us-*

pulun and germisan are given. The chief injury did not appear immediately upon treatment, but only subsequently by the substance adhering to the grain. The influence of the temp. is discussed. A germinating temp. of 15° is recommended.

C. C. DAVIS

Nauru and Ocean Islands phosphate (ELLIS) 18. Certain factors influencing the staining properties [for soil bacteria of fluorescein derivatives] (CONN, HOLMES) 11C. Drying S recovered from manufactured gas (CUNDALL) 21.

PFISTER, AUGUST: *Die Bedeutung des Kalkes für Acker und Wiese*. Freising: F. P. Datterer & Cie. 17 pp. M. 40.

Method and apparatus for injecting air under pressure into soils to promote plant growth. CHARLES H. SPENCER. U. S. 1,677,153, July 17.

Apparatus for excavating acid phosphate from "dens" or the like. FRANK M. WEVER. U. S. 1,675,871, July 3.

Insecticide and fungicide. HEINRICH GÜNZLER and OSKAR NEUBERT (to Winthrop Chemical Co.). U. S. 1,677,823, July 17. A polyhydroxy compd. of the benzene series such as resorcinol or pyrogallol is caused to react with HgCl_2 or other suitable water-sol. Hg compd. to form a stable reaction product which is sol. in water and possesses a strong disinfecting action. It is suitable for treating seeds.

Destroying insects and fungi. G. T. GREEN. Brit. 280,695, Oct. 28, 1926. A compn. suitable for use on trees is prepd. by soaking quassia chips in a hydrocarbon such as "petrol," filtering and mixing the filtrate with linseed oil and varnish.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Fermentation in closed tanks. M. ROSIER. *Bull. assoc. élèves inst. sup. fermentations Gand* 29, 229-36(1928).—A description of the process with a discussion of its merits and drawbacks.

A. PAPINEAU-COUTURE

Some top fermentation processes. P. PETIT. *Brasserie et malterie* 18, 17-21, 33-6, 49-53(1928).—Essentially a discussion and comparison of French and English practice at the present time, bringing out their relative merits and drawbacks.

A. PAPINEAU-COUTURE

Factors affecting the stability of beer. J. RAUX. *Brasserie et malterie* 18, 36-40, 53-8(1928).—An address discussing the chief constituents of beer and the manner in which they can favor the appearance of turbidity.

A. PAPINEAU-COUTURE

Filtration (in the brewery). P. PETIT. *Brasserie et malterie* 18, 65-9(1928).—From a discussion of the mechanism of filtration and the troubles encountered in filtering worts and beers, P. suggests that most of the troubles could be eliminated by adding an easily filterable substance with large surface area, filtering without pressure on a relatively coarse filtering medium, and then refiltering the filtrate.

A. P.-C.

p_H Measurements (in the brewing industry). P. PETIT. *Brasserie et malterie* 18, 82-6(1928).—As the variations in p_H encountered in the brewing industry are small, and as the constituents of worts are extremely sensitive to very small variations in p_H , in order to be of any real value p_H detns. should be accurate to 0.02-0.03, which can be obtained only electrometrically. The difficulties inherent to carrying out such detns. on brewery products are outlined.

A. PAPINEAU-COUTURE

Detection of sarcinae and saccharobacilli in the brewing industry. JULIEN NYS. *Bull. trimestr. assoc. élèves école sup. brasserie Louvain* 28, 21-37(1928).—The best culture media for sarcinae are horse urine and wort to which has been added autolyzed yeast; as solid medium, horse urine and gelatin are suitable. The optimum p_H is about 7.0; but by taking certain precautions it can stand as low as p_H as 4. SO_2 and mustard oil are of practically no value as antiseptics, and moreover could not be used because of their odor and taste. p_H has a much more marked influence on the development of saccharo-bacilli than on that of sarcinae. The best medium for isolating saccharobacilli is wort-gelatin-alc.; but pasteurized beer is preferable as a culture medium.

A. PAPINEAU-COUTURE

Alcohol content of carbon dioxide wash-water from closed fermentation vessels. E. LÜDDEK. *Z. Spiritusind* 51, 1-2, (1928).—In consequence of condensation in the upper part of the fermentation vessel, not more than about 0.4% of the total alc. pro-

duced is usually carried over. This amount varies with the vol. of liquid in the fermentation vessel as shown by a test in a 10,000-l. vessel. When 3000, 6000 and 9000 l. were used, 400 l. of wash-water contained 0.0, 0.8 and 1.5% of alc., respectively.

A. SCHULTZ

The differentiation of artificial and natural wines with the aid of the analytical quartz lamp. J. WERDER AND C. ZACH. *Mitt. Lebensm. Hyg.* 19, 147-52 (1928); cf. *C. A.* 22, 1823. Artificial wines show a blue luminescence in filtered ultra-violet light; natural wines do not. The wines must be decolorized by a good brand of decolorizing carbon before analysis. Judgment of the intensity of the luminescence is made by comparing with a scale worked out on glycerol. Nothing is known about the cause of the luminescence.

J. C. JURRGENS

The acid flavor of wines and their hydrogen-ion concentration. G. CHABOT. *Bull. assoc. élèves inst. sup. fermentations Gand* 29, 205 (1928). The acid flavor of wines is essentially a function of negative acid ions and not of the H-ion concn. With equal H-ion concn., the acid flavor increases proportionally to their total acidity (detd. by ordinary titration). The neg. ions of strongly dissociated acids have less influence on the flavor than those of weakly dissociated acids. High mol. wt. acid radicals have the greatest effect on the gustative papillae. Under certain conditions, doubling the total acidity may render the wine undrinkable though it may not change the pH .

A. P.-C.

Clarification and precipitation phenomena in the course of the manufacture of beer. LUERS. *Der Brauerer Techniker*, Wien, No. 4, April, 1928; *Brasserie et malterie* 18, 99-106 (1928). A general discussion of their mechanism.

A. P.-C.

Conditions of the surface of yeast as a factor in fermentation. CLERK RANKEN AND JAMES BELL. *J. Inst. Brewing* 34, 265 (1928); *Brasserie et malterie* 18, 110-1 (1928); cf. *C. A.* 22, 300. It has been found that the phys. conditions of the various deposits mentioned in the preceding article are extremely sensitive to the action of numerous substances which may be present in beer, and consequently the effects of each deposit are not specific. Peptone tannin, for instance, retards fermentation, but in the presence of a trace of Fe it becomes spongy and less coherent, and fermentation is more active than in the absence of the deposit.

A. PAPINEAU-COUTURE

Results obtained with a wort filter. STRASSMANN. *Kaus* Nov. 23, 1927; *Brasserie et malterie* 18, 120-1 (1928). A discussion of its advantages and disadvantages.

A. PAPINEAU-COUTURE

Conservation of the food value of barley in its conversion into beer. COMRIE. *J. Inst. Brewing* 34, 284 (1928); *Brasserie et malterie* 18, 126-7 (1928). Figures are given showing that beer has a nutritive value equiv. to about 67% that of the barley used in its manufacture.

A. PAPINEAU-COUTURE

The acidity of malts. J. DE CIERCK. *Bull. trimest. assoc. élèves école sup. brasserie Louvain* 28, 1-16 (1928). From the analysis of 217 samples C. concludes: (1) There does not seem to be any relationship between the acidity (expressed as pH) and the other analytical data detd. (degree of fermentation, time of saccharification, color, sugars in ext., length of germination). (2) The nature of the barley has but little influence on the pH value of the malt, but the conditions of malting having a preponderating influence thereon. (3) The nature of the barley and the conditions of malting both have a large influence on the buffer no.

A. PAPINEAU-COUTURE

The analysis of malt. E. BEKAERT. *Bull. assoc. élèves inst. sup. fermentations Gand* 29, 237-9 (1928). A brief discussion of the interpretation of malt analyses from the standpoint of the results to be expected in the brewery, with a plea for the unification of methods of analysis.

A. PAPINEAU-COUTURE

Manufacture of fermentation vinegar during the decade of 1830. HEINRICH KREIPE. *Deutsche Essigind.* 32, 299-11 (1928). An account of conditions prevailing at that period.

W. O. F.

Inactive tartaric acid in the tartaric acid industry. F. HECKELE. *Chem. Ztg.* 52, 405-7 (1928). It outlines the conditions favoring the formation of inactive tartaric acid during the treatment of the d -acid in the industry, and the simple technical precautions which are taken to reduce its amt. to a minimum.

A. L. HENNE

Biological purification of water for brewing (STRELL) 14.

SCHNEIDER, HANS: *Die biologische Betriebskontrolle des Brauereibetriebs*. Vol. 14 of "Enkes Bibliothek f. chemie u. Technik." Stuttgart: F. Enke. 430 pp. M. 20; cloth, M. 22.

ZELLNER, HEINRICH, AND WALTER, ERICH: *Leitfaden für die Untersuchung und Beurteilung der Weinbrennprodukte: Weindestillate, Weinbrände und Weinbrand-Verschritte.* Berlin: Verlag Chemie (Komm. H. Haessel Kommgesch, Leipzig.) 68 pp. M. 3.50.

Dehydrating alcohol. WARREN K. LEWIS (to Standard Oil Development Co.). U. S. 1,676,700, July 10. An aq. soln. contg. less than 95.6% alc. is distd. under an abs. pressure corresponding to not more than 6 in. Hg, a distillate is recovered contg. more than 95.6% alc. and the distillate is fractionated under a pressure of at least 100 lbs. per sq. in. to leave a substantially anhyd. residue and obtain a distillate contg. less than 95.6% alc.

Absolute alcohol. DONALD B. KEYES (to U. S. Industrial Alcohol Co.). U. S. 1,676,735, July 10. A mixt. of 3 liquids such as alc., water and C_6H_6 , which form a ternary min. const. b. p. mixt. which upon condensing settles into layers, is distd. to obtain one of the liquids such as alc. in substantially pure form as a residue, the const. b. p. mixt. evolved is condensed and allowed to sep. into layers; one of the layers is rectified to recover at least a portion of one of the liquids such as alc. which is returned to the mixt. being distd. and the other layer is treated to recover at least a portion of the third liquid in concd. form which is also returned to the mixt. being distd. An app. is described.

Yeast. ALFRED POLLAK. U. S. 1,677,529, July 17. Yeast is propagated in a nutrient soln., with aeration, and at the period of yeast development at which the reproduction has considerably slowed down there is added a second portion of culture yeast, the assimilative properties of which for nitrogenous compds. have been increased by subjecting the yeast to a treatment with a soln. contg. albumin-digesting enzymes and also enzymes capable of decomp. hemi-cellulose, and thereafter to a preliminary fermentation; spent-wash resulting from an alc. fermentation is added to the preliminary mash or wort.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Determination of arsenic in arsenobenzenes. A. KIRCHER AND F. VON RUPPERT. *Pharm. Zentralhalle* 69, 17-8(1928); cf. *C. A.* 18, 880.—Comparative expts. are described, using the authors' method along with that of Stollé and Fechtig, as also that of De Myttenaere (*C. A.* 17, 2471). The differences noted are negligible. The authors' method gave results slightly above those obtained by other methods. R. C. A.

Synthetic fixators for perfumery. W. A. POUCHER. *Am. Perfumer* 23, 236(1928).—The choice of fixator is detd. largely by the type of perfume blended. The heavy amber type will contain patchouli and vetivert which are in themselves excellent fixators, but the permanence of the perfume will be much improved by the judicious addn. of labdanum, benzoin and myrrh together with musk and ambergris. To a very large extent the problem is closely assoc. with that of the boiling points of the perfume constituents. Vetivert and sandalwood oils have a high boiling point and are accordingly excellent fixators. Whenever it becomes difficult to choose a combination of high-boiling odoriferous essential oils because of the particular odor note desired, recourse may often be advantageously had to synthetic chem. fixators possessing little or no odor and boiling well above 200°, as arosol, resorcinol diacetate, Et, Bu and Am phthalate, benzyl benzoate and tricresyl phosphate. These synthetics are particularly useful in the rose, jasmín, narcissus, lavender and cologne types. In soap perfumery, fixation is of equal importance. A very stringent test may be made in an endeavor to find a suitable fixator by taking 10 g. of cheap milling base and dissolving it in 30 cc. of EtOH subsequently made slightly alk. with NaOH. To this is added 10 cc. of a 1% alc. soln. of the compounded oils contg. 10% of synthetic fixator. Heat the flask 2 hrs. in a water bath under a reflux. If after cooling the contents are still fragrant, the fixator deserves a very extensive application. W. O. E.

Plant, leaf and flower drugs, their adulteration and substitution during the year 1927. C. HAHMANN. *Apoth. Ztg.* 43, 697-700(1928); cf. *C. A.* 22, 841.—A discussion of certain typical cases involving both common and obscure drugs. W. O. E.

Sulfur præcipitatum. ERNST PFAU. *Apoth. Ztg.* 43, 740-2(1928).—The Ger. Pharm. provides for 3 forms of S, sublimed, purified and pptd. These 3 preps. differ not only in form but also in size of particles. A microscopical study has been made of the 3 products and micrograms are presented. W. O. E.

Functions of fixatives. H. STANLEY REDGROVE. *Perfumery Essent. Oil Record* 19, 217-8(1928).—In addn. to endowing perfumes with the quality of permanence, fixatives seem, in certain cases at least, to perform the function of binding the constituent odors together and of making them into a harmonious whole. The action of fixatives may be physical (physico-chemical), chem. or physiological. Fixatives are materials of high b. p., i. e., with small or even negligible vapor tensions at ordinary temps. The effect of adding small quantities of such materials to volatile perfumes in which they are sol. is to decrease the vapor tension and hence to retard the evapn. of the perfume. They will act differently on the various ingredients in accordance with the mol. wt. and quantity present of each of these. Fixatives are as a rule materials of very complex structure and hence have high mol. wts. Perfumes, like wines, improve by maturing, and very many of the odorous substances used in perfumery are chemically unsatd. and susceptible of chem. combination with other substances, i. e., with the fixatives themselves or one or more of their individual components. The physiol. effect of the specific odor of the fixative itself in combination with the odors of the other constituents of a perfume is discussed. W. O. E.

Essential oil of Myoporum latum Forst (the Ngaio). F. H. McDOWALL. *Perfumery Essent. Oil Record* 19, 221-3(1928).—The essential oil obtained by distn. of the leaves with dry steam in a yield of 0.1 to 0.3% (dry leaves) had a reddish brown color, and a sweet, malt-like odor. It had the following characters. d_{20}^{20} 1.022-1.026, n_D^{20} 1.4790-1.480; $[\alpha]_D$ in CHCl_3 16.5°, sapon. no. 8-22; sol. in $1/2$ its vol. of 90% alc. and in 45 vols. of 70% alc. The main fraction b_{71} 183° proved to be a ketone having the compn. $\text{C}_{15}\text{H}_{22}\text{O}_2$, which gave a *p*-nitrophenylhydrazone, m. 103°, and a semicarbazone, m. 120-2° (decompn.). The oxime, thiosemicarbazone, phenylhydrazone, and *p*-bromophenylhydrazone were non-cryst. The ketone has been designated *ngaione*. It had a slight reducing action towards Fehling soln. and ammoniacal AgNO_3 , but would not react with aldehydic reagents and reacted only sluggishly with NH_4OH and thiosemicarbazide. Treatment with Na and abs. EtOH gave a secondary alc., *ngaioi*, $\text{C}_{15}\text{H}_{24}\text{O}_2$, a lemon-yellow oil with a faint sweet odor. It failed to revert to *ngaione* on treatment with CrO_3 in AcOH soln. No cryst. deriv. of *ngaioi* was obtained; a monoacetate was prepd. which distd. with decompn. at 29 mm. pressure. The K salt and Me ether of *ngaioi* were prepd. The conclusion that *ngaioi* is a diolefin is confirmed by the results of hydrogenation, both *ngaione* and *ngaioi* taking up 2 mol. proportions of H to form tetrahydrongaione and tetrahydrongaioi, which were then fully satd. Heated with Ac_2O and NaOAc, tetrahydrongaioi gave a monoacetate. When *ngaioi* in aq. alc. is treated with H and Skita's colloidal Pd, and the product distd. repeatedly *in vacuo*, a small amt. of glycol, $\text{C}_{15}\text{H}_{26}\text{O}(\text{OH})_2$, is obtained through opening of one of the oxide rings. With H and Pt black, *ngaioi* gave in AcOH soln. a different glycol, of the same ultimate compn., which decompd. with loss of H_2O on distn. in high vacuum. Both glycols formed diacetic esters. Treated with CSCl_2 in $\text{C}_2\text{H}_5\text{N}$, followed by alc. KOH, *ngaioi* gave *dehydrongaione dioxide*, $\text{C}_{15}\text{H}_{22}\text{O}_2$, a yellowish oil, unstable in the air, and presumably a triolefinic compd. Both rings of tetrahydrongaioi can be ruptured by means of HI in glacial AcOH, with resulting formation of a polyiodide acetate, probably $\text{C}_{15}\text{H}_{24}\text{I}_2\text{OCOCCH}_3$. While the absence of a carbocyclic ring in *ngaione* has been demonstrated, it is not yet possible to put forward even a tentative constitutional formula for this substance. The results so far obtained indicate the presence of a ketone group, 2 oxide rings and 2 double bonds, and absence of a carbocyclic ring. The stability of the oxide rings to H_2O , Ac_2O , dil. H_2SO_4 , and Na and alc. show fairly definitely that an ethylene oxide ring is absent (cases are, however, known of ethylene oxide rings which possess extraordinary stability, e. g., mannite anhydride). A furan ring may be present in the *ngaione* mol. W. O. E.

Estimation of eugenol. W. A. N. MARKWELL and L. J. WALKER. *Perfumery Essent. Oil Record* 19, 169(1928).—A modified technic is suggested, as follows: 2 cc. of the oils measured from graduated pipets are introduced into each of several Gerber milk tubes contg. 16 cc. of 5% KOH soln. Stopper and shake at 5 min. intervals during 30 min. at room temp. Now add another 4 cc. of 5% KOH soln. to each and centrifuge the tubes for 5 min. Read vol. (V) of the uncombined oil and calc. % of eugenol from: $\% = 100 - (V \times f \times 50)$, in which f = the factor required to convert divisions on the Gerber scale into cc. W. O. E.

Testing medicinal glassware. FISCHER and HOKKHEIMER. *Pharm. Ztg.* 73, 777-8(1928).—An amplification of the Ger. Pharm. method for testing the quality of medicinal glassware, notably the quadratric types, by titrimetric or colorimetric procedures, with bromothymol blue as indicator. W. O. E.

Stability of cod-liver oil and phosphorus emulsion. P. BOHRISCH. *Pharm. Ztg.* 73, 778-9(1928).—In general it is found that all emulsions of this character even when prepd. with the greatest care and addn. of some preservative show deterioration in a comparatively short time. After the lapse of 2 to 3 weeks the content of free P has measurably decreased, while after 4 to 6 weeks no free P is any longer detectable.

W. O. E.

Content of homeopathic iron triturations. ALFRED KUHN. *Pharm. Ztg.* 73, 827-8(1928).—It has been previously shown that the Fe content of the 1st potency is usually too low, while in the following potencies D₂ to D₄ the Fe values are almost invariably too high, thus indicating some error in the operation of trituration. An attempt is made to show exptly. how by too conscientious or protracted trituration the soft Fe is partially caught or lost in the pores of the mortar. The Fe in the various potencies examd. was detd. colorimetrically, by ashing the sample, soln. of the residue in aqua regia, addn. of K₄Fe(CN)₆, diln. to a standard vol. and comparison with known solns.

W. O. E.

Analyses of American peppermint oils. E. W. LAZELL. *Perfumery Essent. Oil Record* 19, 183-4(1928).—Tabulated results covering analyses of oils (84 samples) from peppermint grown in Oregon and Washington are presented for the 2 seasons of 1926 and 1927. All the samples gave the test for dimethyl sulfide and were sol. in 4 parts of 70% EtOH.

W. O. E.

Arsenobenzenes. Methods of analysis and chemical evaluation. ST. WEIL AND W. POPLAWSKI. École sup. du service de santé, Varsovie. *Rapport. IV Congrès Internat. Méd. Pharm. Milit.* 1927, 24 pp.—Arsenobenzene preps., of which neoarsphenamine or neoarsenobenzene is an example, are difficultly analyzable mixts. of variable compn. The identity of a product as an arsenobenzene deriv. and not a false product can be established by reactions given in pharmacopeias. The As content, normally 19-21%, or 17-21% in some countries, is detd. by the De Myttenaere method, slightly modified, which gives concordant results; this involves iodometry in alk. soln. Since a neoarsphenamine prepn. may contain impurities and decompn. products, which are toxic, its relative harmlessness must be detd. The index DM¹, representing the amount of As precipitable by H₂S, measured in cc. 0.01 N I soln., helps to establish the degree of toxicity and the origin of a given product. So also does the index SK², which, when multiplied by 0.00375, represents the amount of As contained in the filtrate after pptn. by H₂SO₄ of 0.1 g. of substance. But a more rapid and accurate method than either of these is needed. The initial index of refraction of a 10% aq. soln. of neoarsenobenzene, and the curve representing the change of this index with time, are of value in establishing the origin and the toxicity of a product.

MARGARET W. MCPHERSON

Ichthyolic medicinal preparations. G. L. STADNOKOV. *Papers Karpov Chem. Inst. Bach Memorial Vol.* 1927, 174-97.—To obtain ammonium ichthyolsulfonate the tar derived from bituminous shales is distd. and the ichthyl obtained is sulfonated; a viscous mass possessing the property of killing microorganisms is thus obtained. It has been shown by H. Scheibler that the best and most active germicidal fraction of ichthyl is that which boils between 160 and 190°, being the richest in homologs of thiophene. Many medicinal preps. contain but little of the active fraction and their efficacy is, therefore, very small. S. devised the following analytical method, which permits detn. of the amount of the thiophenic fraction contained in an ichthyolic prepn.: Treat 20-30 g. in a separatory funnel with 20% H₂SO₄, dissolve the tar which seps. in an excess of ether, remove the aq. layer and repeatedly treat the ethereal layer with normal alkali for extn. of sulfonic acids. Wash the ethereal layer with a small quantity of water, drive off the ether, ext. the residue with light benzine (b. up to 60°) to free it of Na salts of sulfonic acids, dry the benzine layer over fused CaCl₂, filter, and distil from a weighed flask on a water bath. Weigh the residue, which represents the neutral oils. In order to manuf. ammonium ichthyolsulfonate, ichthyl must first be deodorized, for which purpose Scheibler prescribes boiling it either with NaNH₂ or with metallic Na. This method being expensive, S. recommends replacing it by a treatment with formalin in presence of naphthasulfonic acids (Petrov's contact catalyzer). Ichthyl is heated to 70-80°, a mixt. consisting of formalin and Petrov's catalyzer is introduced gradually under stirring and the stirring is continued 4-6 hr. at the same temp. after which the oil is steam-distd. In this treatment mercaptans, thiophenols and some unsatd. hydrocarbons condense with formaldehyde under the influence of the catalyzer, and the remaining oil is odorless and enriched in thiophene.

BERNARD NELSON

Extractum fluidum Valerianae. CHR. SCHOUSEN. *Dansk. Tids. Farm.* 1, 500-8

(1927).—S. discusses several suggestions already made regarding the method of prepn. of extractum fluidum Valerianae to be recommended for the next revision of the Danish Pharm. He also had made a series of extns. by the percolation and the repercolation methods from drugs obtained from Thuringen, Hartz and Japan. The results were: (1) Greater yields were obtained than were given by the Danish Pharm. for '07. (2) Greater yields were obtained when an alc. soln. was used instead of H_2O . (3) There is not much difference in yields between the 2 methods. (4) The yield of exts. in the repercolation method was practically the same when the processes were continued for 48, 96 or 144 hrs. (5) The yields of exts. were the same when 1-3, 1-2 or 1-1 alc- H_2O mixts. were used for repercolation, but slightly less with the 2:1 mixt. (6) The fluidext. repercolated with 1-3 and 1-2 alc- H_2O mixts. gave a clear soln. in H_2O but the exts. from 1:1 and 2-1 mixts. were insol. in H_2O . S. recommends using the repercolation method with an alc- H_2O mixt., and continuing extn. for 2 days (48 hrs.).

O. A. NELSON

Repercolation of fluidextracts. J. SCHMELTZ. *Dansk. Tids. Farm.* **1**, 508-9 (1927).—S. points out that Extr. fluid. Valerian. obtained by repercolation with a mixt. of concd. alc. and distd. H_2O in the ratio of 1-4 as suggested by Bang (*C. A.* **21**, 300) cannot contain the amt. of alc. required by the Danish Pharm. The complete ext. obviously contains some of the drug in question and cannot therefore contain 1000 g. extr. mixt. per kg. ext., and therefore not 200 g. alc. which the Danish Pharm. requires. If one places the av. drug (dried material) content at 17%, then in 1 kg. there are 170 g. dry material, and 830 g. alc. aq. mixt. contg. 20% alc. or 166 g. A similar point can be made in regard to the addn. of glycerol to the extg. mixt. Bang suggested adding the same % glycerol as the percent desired in the finished ext. S. points out that this is not possible, if any dry material is extd., e. g., an ext. contg. 20% dry material will contain only 8% glycerol whence 10% was added to the extg. mixt. S. suggests the following formula for the prepn. of extg. mixt.: alc. concn. = 20 g.; distd. H_2O = $(100 - x) g.$, whence x is the concn. of dry material required in the ext. E. BANG. *Ibid.* 537. B. admits the correctness of Schmeltz's remarks, and points out that the main purpose of his own article was to call attention to a method of obtaining fluidexts. without any kind of heating and one whereby all the active principles of the respective drugs could be obtained, also to point out a method that could be used by the smallest drug houses (drug stores). B. also admits that Schmeltz's formula is more accurate than his.

O. A. NELSON

Contribution to our knowledge of the oxidation of spirits of turpentine. J. TERPOUGOFF. *Bull. inst. pin.* No. 48, 103-5 (May 15, 1928). A consignment of Portuguese spirits of turpentine was found to be turbid on reaching Antwerp. It filtered easily through paper, but the filtrate again became turbid after a few days. After standing several weeks, 70,000 kg. of the turpentine gave 80 kg. of air dried deposit, which consisted mainly (on the H_2O - and turpentine free basis) of Zn formate (with possibly also a small proportion of $Zn(OAc)_2$, together with some H_2O insol. Fe salts (probably of higher org. acids). The formation of the deposit is undoubtedly due to autoxidation of the spirits of turpentine, which was catalyzed by the galvanized Fe drums used, acid oxidation products of unknown constitution having attacked the metals. The first products of oxidation are acids of approx. the same mol. wt. as abietic acid, which form Zn and Fe salts which are sol. in spirits of turpentine, these under a secondary decompn. change into formic acid, giving insol. Zn formate.

A. P.-C.

Relationship between the solubility of geraniol in alcohol and its degree of purity. R. ERNEST MEYER. *Parfumerie moderne* **21**, 96-7 (1928). Pure geraniol is fairly easily sol. in 50% alc., but the impurities (sesquiterpenes) which accompany it in the com. products are very difficultly sol., so that the soly. is an indication of the purity of the product. As it varies considerably with temp., the best procedure is to mix 1 cc. of sample with 15 cc. of 50% alc. and note the temp. at which sepn. into 2 phases (indicated by turbidity) appears or disappears, which can easily be detd. with an accuracy of $1/3^\circ$. Results thus obtained with 22 samples having a geraniol content of 96.6-91.5% geraniol (detd. by cold formylation) are tabulated and plotted, the temps. varying from 8 to 32° .

A. PAPINEAU-COUTURE

Aromatic lichens: evernia and sticta. R. CERBELAUD. *Parfumerie moderne* **21**, 98-110 (1928). In French and English. A review of their chemistry with a no. of formulas for their use in perfumery.

A. PAPINEAU-COUTURE

Neroli. WALTER TREFF. *Parfumerie moderne* **21**, 123-5 (1928).—A brief review of its chemistry.

A. PAPINEAU-COUTURE

Iris. ÉTABLISSEMENTS ANTOINE CHIRIS. *Parfums de France* **6**, 123-40 (1928).—

In French and English.—A review of its cultivation, process of extn., chemistry and use in perfumery.

Oil of celery. ÉTABLISSEMENTS ANTOINE CHIRIS. *Parfums de France* 6, 163-70 (1928).—In French and English.—A review of the chemistry of oil of celery.

The occurrence of harmine in a South American liana (yagé). F. ELGER. *Helv. Chim. Acta* 11, 162-6 (1928).—Yagé is a plant of the Amazon region whose botanical nature is unknown. By the extn. of yagé a white, cryst. alkaloid, m. 263-264°, was obtained. From its chem. and phys. properties it was identified as harmine.

The synthesis of iododihydrochaulmoogric acid and its ethyl ester. ARTHUR L. DEAN, RICHARD WRENSHALL AND G. FUJIMOTO. *U. S. Pub. Health Service Pub. Health Bull.* No. 168, 28-30 (1927).—Iododihydrochaulmoogric acid (I) (12 g. from 50 g. chaulmoogric acid and I₂), white, m. 68-9°, $[\alpha]_D^{25.5}$ 6.24 (in 5% CHCl₃ soln.), acid value 139.8, sapon value 274.8, insol. in H₂O, sol. in org. solvents. If the chaulmoogric acid reacts as cyclopentene, I is either μ -(2- or 3-iodocyclopentyl)tridecoic acid. Ethyl ester (from I and Et₂SO₄) m. 35-6°. This latter is expected to be of clinical value in the treatment of leprosy. Chaulmoogric acid and I₂ gave a black tarry substance instead of diiodochaulmoogric acid.

The preparation of 4-chaulmoogrylaminobenzeneearsonic acid. MARGARET M. DEWAR. *U. S. Pub. Health Service Pub. Health Bull.* No. 168, 31-2 (1927).—4-Chaulmoogrylaminobenzeneearsonic acid, from chaulmoogryl chloride and arsanilic acid, decomposes 230°, sol. in hot EtOH, hot AcOH and aq. alkalies, insol. in H₂O, Et₂O, CHCl₃, EtOAc and C₆H₆. This insoly. makes the compd. unfit for being used in the treatment of leprosy.

The preparation of chaulmoogryl alcohol. MARGARET M. DEWAR. *U. S. Pub. Health Service Pub. Health Bull.* No. 168, 33-5 (1927).—Since the yield of chaulmoogryl alc. (I) prepd. according to Power and Gornall (*J. Chem. Soc.* 85, 851 (1904)) was small the method of Prins (*C. A.* 18, 1815) was used to reduce the ester of chaulmoogric acid (II) to the alc. Forty g. of I was obtained from 100 g. of II; m. 36°, $[\alpha]_D^{25}$ 58.5 (in 5% CHCl₃ soln.), I value 95.1.

Action of picric acid on silicotungstate of tropine (tropanol), the reaction permitting detection and tracing the hydrolysis of atropine. RENÉ HAZARD. *J. pharm. chim.* 7, 255-62 (1928).—In the sepn. of atropine (A) from tropanol (B) by means of Bertrand's reagent (C) (cf. *C. A.* 20, 1303), the optimum concn. for total pptn. of A and simultaneous non-pptn. of B is 2% HCl in a diln. of 1:1500 or 1:1600. At a lower concn. of HCl, B is also pptd. Upon adding to the clear filtrate 1 cc. of concd. picric acid, pptn. of B takes place at once; in more dil. solns. (e. g., 1:3100) after 20-60 min. The compn. of the ppt. was not detd.; upon heating it leaves much ash. This reaction enables one to observe the march of hydrolysis of A, since pure A after pptn. with C does not yield in the filtrate a ppt. with picric acid. Hence the use of the latter seems to render the reaction with C more sensitive, which probably holds good also in the detection of other alkaloids. A 10% soln. of C satd. with picric acid may reveal traces of alkaloid which C alone could not detect (cf. Guillaume, *C. A.* 21, 2048).

Cocaine and the Maclagan test. PIERRE BRETEAU. *J. pharm. chim.* 7, 329-31 (1928).—The various pharmacopeias differ as to the concn. of the soln. to be tested and the mode of inducing crystn. of cocaine. Adoption of the following procedure by the French Pharm. is recommended: Dissolve 0.1 g. of the HCl salt in 80 cc. H₂O, add 2 cc. of 1% NI₃ (d. 0.995) and mix with a glass rod tipped with rubber; after standing for 5 min. the liquid must be limpid. Then rub the walls of the vessel from time to time, not too vigorously, with a glass rod to end supersatn. A cryst. ppt. of cocaine must form at the bottom, and the supernatant liquid must be limpid to indicate absence of toxic isatropylcocaine (A). If this liquid is opalescent, and the opalescence of the liquid after decanting disappears upon adding HCl, the presence of A is indicated.

Léon Guignard, 1852-1928. ANON. *J. pharm. chim.* 7, 370-2 (1928).—An obituary.

Evolution of the chemistry of organic medicaments. CH. MOUREU. *J. pharm. chim.* 7, 377-80 (1928).—A brief historic review of modern org. remedies, from alkaloids to chemotherapy.

Synthalin, the name regrettably homonymous to that of an older preparation. R. WERTZ. *J. pharm. chim.* 7, 449-55 (1928).—Synthalin (cf. *C. A.* 22, 2031), the recently evolved intended substitute for insulin, is decamethylenediguandine (NH₂.C.(NH).NH.(CH₂)₁₀). In 1913, the same name had been given by Schering to a quinoline deriv.

used as an antirheumatic (cf. *C. A.* 9, 954). Fortunately the rights to the name and process have been ceded recently to the makers of the new synthalin. S. W.

Some adulterations or substitutions of medicaments. E. LÉGER. *J. pharm. chim.* 7, 455-6(1928).—Com. ZnO consisted of ZnCO_3 . Beer yeast contained a large quantity of CaCO_3 . Com. cherry laurel water had a faint odor although its HCN content was 0.1 per 100 (Codex). It was merely a soln. of HCN in H_2O ; BzH was absent, since NH_4OH added to the prepn. failed to produce opalescence caused in the genuine water by the formation of hydrobenzamide. This test should be added in the Codex to enable detection of the fraud described. S. WALDBOTT

Oil-free linseed meal. EMILÉ ANDRÉ. *J. pharm. chim.* 7, 481-6(1928).—The directions of the Codex Supplement (1926) for prepg. oil-free linseed cake (deprive powd. linseed partially or entirely of its oil by cold pressure or by a chem. solvent) do not prevail in manufg. practice. Here, a small quantity of H_2O is added before pressing (at 55-60°), to increase the yield of oil. This causes the mucilage to be set free, rendering the presscake unsightly and unfit for use in emollient cataplasms. The press cake will always retain 6-7% of oil; if no H_2O is added, 12%+. A. applied chem. solvents to the extn. of oil from crushed seeds, and from the cake after cold pressure without addn. of H_2O . The kernels become dust-like and are easily sepd. from the husks which alone carry the mucilage developed on addg. H_2O . The powd. defatted kernel is rich in P and N, and may be used as food for cattle. Some day it will be used as human food when linamarin, the HCN-bearing glucoside, has been eliminated from the plant by proper cultivation and selection. S. WALDBOTT

Silver-ion concentration studies of colloidal silver germicides. II. Changes in the silver-ion concentration of solutions on standing. RALPH B. SMITH. *J. Am. Pharm. Assoc.* 17, 453-4(1928); cf. *C. A.* 19, 3350.—The following method gave stable readings when attempting to detect small variations in Ag-ion concn. The electrode used was an 8-in. piece of No. 14 B and S gage pure Ag wire which was not cemented to the tube. It is placed in boiling 1% KCN soln. for 10-15 min. and rinsed without touching. It is then stored 15 hrs. in a soln. similar to the one to be tested. The solns. used were 1% for the strong type and 10% concn. for the others. The results are tabulated. The changes in Ag-ion concn. which take place in colloidal Ag compds. in the first month are negligible and those occurring in the first 4 months are not believed to be great enough to cause any change in germicidal power. If any of these solns. on aging produce irritation, it must be due to changes in soln. other than Ag-ion concn. L. E. WARREN

The physical and chemical properties of bismuth sodium citrate and bismuth sodium tartrate. W. F. VON OETTINGEN, T. SOLLMANN AND H. H. SCHWEID. *J. Am. Pharm. Assoc.* 17, 540-3(1928).—The salts studied were "dibismuthyl mono-Na citrate" (A) and "bismuthyl bismuthio-Na tartrate" (B) in 10% soln. A is practically neutral (p_H 7.2-7.4) while B is distinctly alk. (p_H 8.2-8.4). Changes in p_H from 7.0 to 7.9 do not ppt. A, while pptn. of B begins at p_H 7.6 and increases with acidity. A ppts. with CaCl_2 but this may be prevented by adding Na citrate. B is pptd. by a large no. of the alkali salts of strong mineral acids. A in 5% soln. is not pptd. by Locke's soln., whereas a 5% soln. of B is pptd. Neither soln. ppts. proteins. A may give a slight ppt. with the Ca of serum. B is pptd. by other mineral salts. The diffusibility of each is about the same. Solns. of A may be sterilized by boiling. B is pptd. by heat. Solns. of either may be rendered sterile by 0.4% tricresol. L. E. WARREN

The corolla of *Monarda fistulosa*. KARL H. RANG. *J. Am. Pharm. Assoc.* 17, 525-7(1928).—Florets were collected in 1924. Moisture detd. by the xylene method was 75, 78 and 78%; ash 8.11, 8.08 and 8.10%; H_2O -insol. ash, 2.46, 2.84 and 2.79%; volatile oil 3.1%; d_{25} 0.9740; phenols 36.3%. The regenerated phenols were reddish brown. Cavacrol was test positive. Monohydroxythymoquinone was present. L. E. WARREN

Some new and improved tests for morphine and related alkaloids. CHARLES C. FULTON. *J. Lab. Clin. Med.* 13, 750-62(1928).—There are given and described: (1) A new test for morphine, not given by codeine, which is a modification of the iodic-acid ammonia test and might be called the "iodic-acid peroxide test." (2) Methods for making 2 new reagents for the opium alkaloids and their reactions with these alkaloids. (3) An improved method for performing the well-known Pellagri test. (4) Prepn. of a new deriv. of morphine. Codeine and dionine give similar but distinct derivatives. The deriv. is formed by heating the alkaloid in concd. H_2SO_4 soln. to 40° or 50°, and is no doubt a dehydration product. The morphine deriv. is not apomorphine but it gives similar color reactions. (5) Two tests based on the formation of this deriv. The derivative-oxidation test is given by morphine, heroine, codeine and dionine, and

is a new test similar to Pellagri's. (6) Husemann's test is discussed, with particular attention to the difference in the reactions when the H_2SO_4 soln. is heated to 40° or 50° instead of to 100° .

ETHEL W. WICKWIRE

Further researches in the explosibility of anesthetics. A. P. HORNER AND CLYDE B. GARDENIER. *Anesthesia and Analgesia* 7, 69-72(1928).—The explosibility of ethylene mixtures and ether mixtures was tested in a standard Orsat explosion pipet. Downward propagation of the flame was used to distinguish explosion from combustion. The following limits of explosibility were detd. for the various mixts.: C_2H_4 4-14.5%, air 96-85.5%; C_2H_4 5-70%, O 95-30%; C_2H_4 5-35%, N_2O 95-65%; C_2H_4 5-47%, N_2O 85-43%, O 10% (fixed); C_2H_4 5-20%, N 85-70%, O 10% (fixed); C_2H_4 5-55%, O 95-40%, CO_2 5% (fixed); ether 5-14.5%, air 95-85.5%; ether 5-65%, O 95-35%; ether 5-30%, N_2O 85-60%, O 10% (fixed); ether 5-60%, O 90-35%, CO_2 5% (fixed). The dampening effects of CO_2 and N were greatest in mixtures with ethylene-oxygen. Thus, 5% CO_2 added to ether-oxygen did not materially affect the explosive range of the mixt., whereas it had a decided effect on ethylene-oxygen. The same was true of N.

Medicinal composition. ALDUS A. HOOPMAN. U. S. 1,676,554, July 10. A compn. suitable for treating wounds and for other purposes comprises I, PhOH , menthol, glycerol and alc., equal quantities.

Therapeutic organic arsenic compounds. G. NEWBERY and MAY & BAKER, LTD. Brit. 280,613, July 8, 1926. Aryl-1,4-isoxazine As compds. are made by reduction of an arylarsonic acid contg. nitro and oxyacetic acid groups in adjoining positions in the aryl nucleus. With mild reducing agents only ring formation occurs, but with other reductions the starting material may be reduced, with or without isolation of intermediate products, to the corresponding arsenious oxide, arsine halide or arseno compd. 2-Nitrophenoxyacetic acid-4-arsonic acid is reduced with alk. $\text{Fe}(\text{OH})_2$ to 3-hydroxy-1,4-benzisoxazine-6-arsonic acid and by further reduction of the latter with Na hyposulfite 6,6'-arseno-bis-(3-hydroxy-1,4-benzisoxazine) is formed. By similar treatment, 6-acetyl-amino-2-nitrophenoxyacetic acid-4-arsonic acid yields first 8-acetyl-amino-3-hydroxy-1,4-benzisoxazine-6-arsonic acid and then 6,6'-arseno-bis-(8-acetyl-amino-3-hydroxy-1,4-benzisoxazine). Glucose in an alk. medium and hypophosphorous acid also may be used as reducing agents. *o*-Nitroaryloxyacetic acid arsonic acids are made from phenolarsonic acids by treatment with an α -halogenated acetic acid and introducing the NO_2 group either before or after the treatment. An example is given of the prepn. of 6-acetyl-amino-2-nitro-phenoxyacetic acid-4-arsonic acid.

Water-soluble organic compounds of arsenic. MORRIS S. KHARASCH. U. S. 1,677,392, July 17. An arsenious compd. such as *p*-dimethylaminophenylarsenious oxide or other suitable As compd. in which at least one valence bond of the As is attached to an inorg. radical other than that of S, Se or Te and at least one bond of the As attached directly to a C atom of an org. radical is treated, in a solvent such as alc. or acetone with thiosalicylic acid or other similar suitable org. compd. contg. both an acid radical and a sulphydryl group and having the sulphydryl group attached directly to a C atom. The products are suitable for therapeutic use.

Esters of aromatic acids (local anesthetics). ROGER ADAMS and EARNEST H. VOLWILER (to Abbott Laboratories). U. S. 1,676,470, July 10. A γ -halogen propyl benzoate or a similar compd. with a substituted benzoyl radical is added to an excess of dialkylamine and heated for several hr. The product is made alc., excess amine is removed by steam distn. and the γ -dialkylaminopropyl ester of the aromatic acid is extd. with an org. solvent such as ether. The ether is then removed, leaving the free base. If an aminobenzoic acid deriv. is desired, a nitro γ -halogen propyl benzoate is used in-

initially and the base resulting is reduced, *e. g.*, with Sn or Fe and HCl or electrolytically. Details are given for the production of the γ -dibutylaminopropyl ester of *p*-aminobenzoic acid.

Cyclopentenylalkylacetic acid. ROGER ADAMS (to Abbott Laboratories).

U. S. 1,677,123, July 17. Compds. of the general formula
$$\begin{array}{c} \text{CH} = \text{CH} \\ | \\ \text{CH}_2 = \text{CH}_2 \end{array} \text{CH} = \text{CH(R)} -$$

COOZ, in which R stands for C_6H_{13} or other alkyl group contg. 5 or more C atoms and Z stands for H or a substituent such as a metal or alkyl, are described. They are *therapeutic agents* and may be used in the treatment of leprosy and tuberculosis.

Compounds of gall acids. ALPHONSE GAMS and PAUL SCHNEIDEGGER (to Soc. anon. pour l'ind. chim. à Bâle.). U. S. 1,677,554, July 17. Acylated aliphatic diamines such as oleyldiethylethylenediamine are caused to react with a gall acid, to form *therapeutic compds*. Several examples are given.

Ampoules for separate reactive ingredients for making unstable solutions. PHARMAGANS, PHARMACEUTISCHES INSTITUT, L. W. GANS A.-G. Brit. 280,838, July 22, 1926. Structural features.

Antitubercular serum. CONSTANTINE LEVENTIS. U. S. 1,676,997, July 10. A donkey or other suitable animal not normally responsive to tuberculosis is injected with tuberculosis antigen and with serum from man or other animal normally responsive to tuberculosis, and serum is subsequently withdrawn from the treated animal.

Antitoxins and serums. CONSTANTINE LEVENTIS. U. S. 1,676,995, July 10. An animal such as a donkey which is not normally responsive to a specific disease such as human pneumonia or tuberculosis is treated with an antigen, serum from the human or other different species to be protected is then injected into the treated animal and serum for use is subsequently withdrawn from the latter.

Antiseptic. JOHN H. WRIGHT (to Zonite Products Co.). U. S. 1,676,309, July 10. A stable prepn is formed from the Na salt of *o*-dichlorosulfonamide of benzoic acid, K stearate, free stearic acid, water, eucalyptol, bornyl acetate and menthol.

Cleansing and astringent cosmetic. DELLA BRANDON. U. S. 1,675,840, July 3. A mixt. of egg white 240, H_2O_2 soln. 228 and yeast 219 parts is specified.

Solution for use in curling or "permanent waving" of hair. FRANK J. MCKENNA (to Chemical Preparations, Inc.). U. S. 1,677,246, July 17. A 4% aq. soln. of hydrazine hydroxide is used.

Hydroxyethylamide of *o*-hydroxybenzoic acid, etc. WALTER KROPP (to Winthrop Chemical Co., Inc.). U. S. 1,675,500, July 3. This compd. is made by heating methyl salicylate at 180° with aminoethanol until all MeOH formed has been distd. It crystallizes from water and m 119° . Similarly, *m*-cresotinic acid methyl ester and aminoethanol yield a cryst. product m 88° . These compds are antirheumatics and antineuralgics. They are difficultly sol. in water.

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

Contact oxidation of ammonia to nitric acid. V. I. MALYAREVSKII. *J. Chem. Ind. (Moscow)* 4, 122 9(1927); cf *C. A.* 21, 3712.—The detn. of compn. of N oxides formed in the catalytic oxidation of NH_3 to HNO_3 shows that the opinion of Raschig (*Z. angew. Chem.* 18, 1281(1905); *C. A.* 1, 1896) and of Jolibois and Sanfourché (*C. A.* 13, 1055) that NO oxidizes in 2 phases is false. Immediately after contact and also in the whole space between contact app. and nitrite scrubber NO predominates in the gas mixt. The fundamental reaction is $4\text{NH}_3 + 5\text{O}_2 = 4\text{NO} + 6\text{H}_2\text{O}$. The presence in the nitrous gas of an excess of NO det. the character of the reaction in the nitrite scrubber. NaNO_2 is formed by the interaction of NaOH and the NO + NO_2 mixt. Absorption of the latter destroys the equil. and provokes further oxidation of NO. The speed and the degree of absorption of N oxides in the nitrite scrubber depend on the concns. of NO and NaOH, the velocity of the gas current and the intensity of contact of the liquid with the gas. The principal reaction in the absorption towers is $3\text{NO} + 3\text{NO}_2 + \text{H}_2\text{O} \rightleftharpoons 2\text{HNO}_3 + 4\text{NO}$. The formation of HNO_3 with sepn. of $\frac{1}{3}$ of the combined N in form of NO, the retardation of the speed of oxidation with decrease of concns. of NO and O towards the end of absorption, and the dependence of the const. *K* on $t^\circ [(Kt + 10)/Kt = 0.93]$ are the fundamental factors to be considered in the choice of a proper absorption system.

BERNARD NELSON

Synthetic nitric acid in Spain. The plants of the Sociedad Iberica del Nitrogeno. RAMÓN MIRAVALLS. *Quim. Ind.* 5, 4-7(1928) - The Flix plant employs a modification of the Franck-Caro process. NH_3 , made by the Claude process, and air are forced into a diffusion chamber from which the homogeneous mixt. contg. NH_3 passes with great velocity through the combustion chamber. The catalyst is Pt wire gauze, the temp. $800-50^\circ$. The mixt. of NO , N_2 , O_2 and some N_2O_3 passes water-cooled pipes and enters with a temp. of 50° 4 oxidation towers 10 m. high and 80 cm. in diam. filled with Raschig rings, where it streams counter-current against cold HNO_3 . The acid from the condensers, contg. 8-10% free and combined N oxides, is used for this purpose. The low temp. is essential, since it favors absorption and formation of NO_2 and obviates decomn. The mixt. of N_2O_4 and N_2O_3 enters 4 Raschig absorption towers 10 m. high and 1.5 m. in diam., irrigated with HNO_3 , the concn. of which is gradually lowered toward the bottom by injecting water. The gases circulate in these towers alternately upward and downward. The circulation of the gases is effected by an exhauster, that of liquids by a pump of acid resistant V₂A. The pipes are of Al. The waste gases which are expelled into the air contain 6-8 g. HNO_3 per cu. m. The concd. acid from the 1st tower is $36-40^\circ$ Bé and has a fairly high content of N oxides. It passes through a coil immersed in water at 40° and then enters a small tower where a current of air removes the N oxides and carries them to the 2nd absorption tower. The daily capacity of the plant is 7000 kg. HNO_3 or 1000 kg. NH_3 . M. J.

Separation and regeneration of caustic soda in the Harris process of lead refining. R. WINTER. *Eng. Mining J.* 125, 809-12(1928) - In the Harris process (cf. Brit. pat. 245,479 (C. A. 21, 304)) the As, Sn and Sb in the Pb bullion are converted into arsenate, stannate and antimonate by molten NaOH , NaCl and NaNO_3 . The molten spent reagent is drawn off and granulated. The aq. soln. thus produced is brought in contact with more spent reagent till the cold filtrate has a d. of 1.35 (70° Tw.). At this d. Na stannate and antimonate are insol. in the hot soln., while Na arsenate is sol. but ppts. when the soln. is cooled to 25° . The soln. of the spent reagent at d. 1.35 contains approx. 350 g. NaOH , and 85 g. NaCl per l. The treatment of the slurry can be varied to suit its compn. Details are given of the variations to suit two classes of impure Pb: (1) Ag-Pb contg. comparatively small quantities of As and Sb, and no Sn; (2) secondary and residual leads and alloys high in As, Sb and Sn. These variations are given in some detail, with diagrammatic flow sheets. The NaOH - NaCl soln., freed from As, Sb and Sn, is concd., and the recovered NaOH used again in the process. A subsequent article will describe various ways of treating the wet alk. filter cake contg. the cryst. oxy-salts of As and Sn. E. G. R. ARDAGH

The manufacture of barium and strontium nitrates. R. CHEMNITIUS. *Chem.-Ztg.* 52, 465-6(1928). - 98% BaCO_3 is used as raw material except where a very pure product is needed (as for optical purposes), and then BaSO_4 is employed. (a) 1000 kg. BaCO_3 and 1400 kg. HNO_3 (sp. gr. 36° Bé.) are mixed gradually in a 5 cu. m. enamelled kettle with wooden stirring app., heated near the end of the reaction. The soln. is drawn off into a pressure cylinder, filter-pressed, concd. in vacuum pans, centrifuged, washed, dried and sieved. (b) Into a 5 cu. m. wooden vat with stirring app. and heating coil are placed 1000 l. $\text{Ca}(\text{NO}_3)_2$ soln. (35° Bé.) contg. 45% of the salt, diluted with 750 l. condensed H_2O and 1000 kg. $\text{Ca}(\text{NO}_3)_2$ added. While warming 1250 kg. BaCO_3 are added and agitation is continued 4 or 5 hrs. Thus an excess of about 15% $\text{Ca}(\text{NO}_3)_2$ is employed, but is recovered and re-used. The sp. gr. of the $\text{Ba}(\text{NO}_3)_2$ soln. formed is only 10° Bé. at the end of the reaction. The hot soln. is then filter-pressed, the filtrate stirred while cooling in a Cu grainier, the crystals are washed with HNO_3 (1:10) in an earthenware vessel to remove CaCO_3 , centrifuged, washed, dried and sieved. The press cake is boiled with mother liquor from the $\text{Ba}(\text{NO}_3)_2$, and the soln. re-used. $\text{Sr}(\text{NO}_3)_2$ is made from $\text{Sr}(\text{OH})_2$ instead of SrCO_3 . 1400 kg. HNO_3 (sp. gr. 36° Bé.) are mixed with 1500 kg. $\text{Sr}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ in an app. similar to that used for making the Ba salt, but the reaction vessel is smaller, since no evolution of CO_2 occurs. Double decomn. with $\text{Ca}(\text{NO}_3)_2$ is not employed. W. C. EBAUGH

Nauru and Ocean Islands phosphate: The industry and its future. A. F. ELLIS. *New Zealand J. Agr.* 36, 28-30(1928).—The entire production of phosphate rock, about 550,000 tons annually, from Nauru and Ocean Islands is exported to Australia and New Zealand. K. D. JACOB

A method for obtaining potassium ferrocyanide. K. R. LANGE. *Chem.-Ztg.* 52, 440-1(1928).—The method described by F. Chemnitz (Biochem. Z. 139, 394; 152, 122) has certain disadvantages which would make it seem hardly suitable for manufacturing ferrocyanide on the large scale from gas purification masses. For one thing it is not desirable to work with CS_2 as a solvent for S. Trichloroethylene and o-dichloro-

benzene are replacing CS₂ as solvents. S is very sol. in dichlorobenzene at 90°. Other objections are raised to the method of C. because of the expense involved. W. T. H.

Preparation of a vanadium-asbestos contact catalyzer. N. N. EFREMOV AND A. M. ROZENBERG. *J. Chem. Ind. (Moscow)* **4**, 129-34; *J. Russ. Phys.-Chem. Soc.* **59**, 701-14 (1927).—V-asbestos can be used as contact mass instead of the more expensive Pt-asbestos. Its action is based on the easy transformation of quadrivalent to quinquevalent V: $2V_2O_4 + O_2 \rightleftharpoons 2V_2O_5$. It is prepd. by fixing a V compd. on asbestos fibers as either a colloidal film or amorphous, finely divided particles; cryst. compds. would not be active. A soln. of 5 g. NH_4VO_3 in 100 cc. boiling H₂O is reduced either by a soln. of $(NH_4)_2SO_3$, $(NH_4)_2S_2O_4$ or H₂SO₃, e. g., $2NH_4VO_3 + NH_4HSO_3 = (NH_4)_2V_2O_5 + NH_4HSO_4$. On adding to the reduced soln. 2 to 3 g. 25% H₂SO₄ a blue, transparent soln. is obtained: $V_2O_4 + 2H_2SO_4 = V_2O_2(SO_4)_2 + 2H_2O$. Pure asbestos is immersed into the latter soln. in a porcelain dish, stirred up and boiled 10 to 15 min., then cooled to 40° to 50°. Ammonia of sp. gr. 0.92 is added to this warm liquid, without removing the asbestos, until strongly alk.: $V_2O_2(SO_4)_2 + 4NH_4OH = 2(NH_4)_2SO_4 + V_2O_2(OH)_4$. The $V_2O_2(OH)_4$ ppt. settles in the pores and on the surface of the fibers. The contents of the dish are evapd. almost to dryness, the asbestos being stirred constantly. Then the asbestos, which has become brown, is put in a thin layer over asbestos cardboard to dry. The asbestos thus obtained is calcined by placing it in a thin layer on an asbestos sheet and heating in a furnace with free access of air, the temp. being raised gradually to 500° to 600° and held there for about 30 min. This decomposes the NH_4 salts and all V compds. are oxidized to V_2O_5 . To avoid fusing the latter the temp. should not reach 700°. As the catalytic action of V-asbestos is the more energetic the greater the V_2O_5 content, asbestos impregnated as above is given a second impregnation. For this purpose a NH_4VO_3 soln. can be used without being first reduced. In both impregnations asbestos can absorb up to 52.5% of its weight of V_2O_5 . The final product is brittle and cannot be woven. It is therefore advisable to deposit V_2O_5 on asbestos nets or sieves.

BERNARD NELSON

The preparation and properties of the vegetable decolorizing carbons. I. MIURA. *J. Coll. Agr., Imp. Univ. Tokyo* **9**, 101-18 (1927); *Expt. Stu. Record* **58**, 203.—This paper presents a systematic study of the prepn. of decolorizing carbons from the sawdust of the Japanese cedar or sugi (*Cryptomeria japonica*), from the ground wood pulp and sulfite wood pulp of the Japanese spruce or yezomatsu (*Picea jezoensis*) and the Japanese fir or todomatsu (*Abies sachalinensis*), from the alga kajime (*Ecklonia cava*), from birch bark, and from camellia oil cake. Among the compds. added to the org. material before carbonization were Ca acetate, 1, 5, 10 or 20 parts per 100 of sawdust; slaked lime 10, 20, 50 or 100 parts per 100 of sawdust; CaCl₂ 10 or 50 parts; CaHSO₃ 50; crude MgCl₂ 10, 50 or 100; NaCl 50 or 100; K₂CO₃ 50; Na₂CO₃ 50; NaHCO₃ 50; CuSO₄ 50; alum 50; etc. The products were rated according to the percentage of color removed from a standard color soln. by a definite proportion of the C under fixed conditions. It was found that of all the substances added before carbonization, Ca compds. were most effective in improving the quality of the resulting C, slaked lime, or Ca bisulfite followed by slaked lime, giving the best products. Washing out of the ash with water, alkalies, or acids after carbonization was necessary for the highest effectiveness. The presence of alkali metal compds. during charring was found useless or even deleterious, causing fusion of the ash in the charring process. The decolorizing effect of an animal charcoal of best quality is about 3.6 times that of ordinary wood charcoal, and a C prepd. by submitting sugi sawdust mixed with slaked lime to dry distillation after treating it with Ca bisulfite has a decolorizing power about 13.5 times that of animal charcoal of best quality. A C of high efficiency generally passes the filter paper with difficulty; consequently it can easily be filtered off from the soln. A rather detailed discussion of the theory of decolorization by C is included.

H. G.

A new artificial wood. H. HERPER. *Kunststoffe* **18**, 127-8 (1928).—An artificial product which very closely resembles natural wood is made by exposing cellulosic material, such as chips and sawdust, to a steam pressure of about 58 kg. per sq. cm. for 4-5 sec., suddenly releasing the pressure to disintegrate the cellulosic stock into fibers, and subjecting the material mixed with phenol-formaldehyde condensation products to a pressure regulated according to the desired hardness of the finished product. Glue or other artificial binding agent is not necessary. The product is light, an excellent insulator, and has tensile strength 280-365 kg. per sq. cm. and d. close to that of precious woods. It possesses excellent acoustic properties. The phenol-formaldehyde condensation products incorporated in the material are capable of swelling under the action of H₃PO₄ or a mixt. of HCl and H₂SO₄.

BONTFANT HAMILTON

The preparation of HBr in the presence of charcoal (BOZHOVSKI, DANILCHENKO) 6. Absorption plant [for making HNO_3] (U. S. pat. 1,677,409) 1.

CRIVELLI, E.: *Solfato di Rame*. Milan: Ulrico Hoepli. 321 pp. L. 35. Reviewed in *Chem. Met. Eng.* 35, 431 (1928).

Arsenic acid. FRITZ ULLMANN and GERT TREWENDT (to J. Michael & Co.). U. S. 1,677,257, July 17. A soln. comprising As_2O_3 10, water 20 and KClO_4 3.8 parts is heated and a small quantity of HCl is added.

Hydrocyanic acid. PAUL L. MAGILL and PAUL J. CARLISLE (to Roessler & Hasslacher Chemical Co.). U. S. 1,675,366, July 3. Formamide vapor is passed in contact with brass at a temp. of about 300° .

Phosphoric acid. E. URBAIN. Brit. 280,763, Jan. 20, 1927. In making H_3PO_4 by heating together Ca triphosphate, silica and carbonaceous material, a portion of the silica is replaced by alumina or clay to obtain a fusible slag having the compn. of an alumina cement. The mixed P and CO formed are mixed with water vapor and a halogen acid and passed over porous amorphous carbonaceous material as described in Brit. 278,578 (C. A. 22, 2642) and H_3PO_4 and a gas of the compn. of water gas are obtained.

Carbon dioxide. FREDERICK H. KELLIHER. U. S. 1,675,497, July 3. Pulverized coal or other finely divided carbonaceous material is burned in a closed furnace in the presence of sufficient air to insure substantially complete combustion without producing CO and combustion products are withdrawn from the furnace by operation of a water piston suction pump and passed through a scrubber to a gas-receiving tank through a separator from which water is returned to the upper part of the scrubber. App. is described.

Sodium hydrosulfide. HENRY HOWARD (to Grasselli Chemical Co.). U. S. 1,675,491 July 3. An alk. earth metal sulfide such as Ba sulfide is dissolved in a soln. contg. Na hydrosulfide and the soln. is treated with NaHCO_3 .

Sodium phosphate. HENRY HOWARD (to Grasselli Chemical Co.). U. S. 1,676,556, July 10. A soln. of H_3PO_4 contg. also sulfate and fluosilicate is treated with a Na compd. such as Na_2CO_3 and subsequently with a Ba compd. such as BaCO_3 to ppt. the SO_4 ; the soln. may then be further treated with alkali to ppt. Fe and Al compds.

Soluble carbonates from fluorides. MAX RUCHNER (to Albert F. Meyerhofer). U. S. 1,675,786, July 3. A fluoride such as NaF is caused to react with CaCO_3 or other carbonate which in the reaction will form an insol. fluoride; the reaction is effected under superatm. pressure (suitably in the presence of CO_2).

Apparatus for cooling salt solutions for crystallization, etc. RUSSELL W. MUMFORD (to American Potash & Chemical Corp.). U. S. 1,676,277, July 10.

Sulfur composition. CARLETON ELLIS. U. S. 1,676,604, July 10. A compn. suitable for use as a constituent of moldable compns., etc., comprises S together with a S-miscible and S-contg. resinous material such as a phenol S resin.

Apparatus for making powdered oxides from lead lumps or balls. CLARENCE A. HALL. U. S. 1,675,345, July 3.

Producing granules from steatite or similar materials. WM. H. ALTON (to R. T. Vanderbilt Co., Inc.). U. S. 1,677,701, July 17. Pyrophyllite sericite or steatite or other soft non-vitreous rock having a fibrous or laminated structure is crushed, particles of granule size are sepd. and are subjected to a vitrifying treatment, e. g., by heating to 1200 – 1370° , to reduce the absorptive properties of the granules and render them suitable for roofing or other purposes.

Regenerating catalysts. SELDEN CO. Brit. 280,712, Nov. 26, 1926. Catalysts contg. V compds. or the like, and which may have deteriorated from use in the oxidation of C_2H_4 or similar catalytic oxidation processes, are regenerated by treatment with a suitable substance such as halogen, non-metallic halogen compd., non-metallic acid or its anhydride, ozone or H_2O_2 which is volatile at 550° or below and does not leave a residue which is non-volatile when heated with O. Numerous detailed examples are given in which Cl, air, ethylene chloride, steam, nitrosyl chloride, H_2O_2 , ozonized air, H halides, NH_3 halides, S chloride, sulfuryl chloride, thionyl chloride, phosgene and similar compds. may be used as regenerating agents.

Condensation product of urea with formaldehyde. ALPHONSE GAMS and GUSTAV WIDMER (to Soc. anon. pour l'ind. chim. à Bâle). U. S. 1,676,543, July 10. Condensation is effected in the presence of active C, which is afterward eliminated, e. g., by filtration.

Condensation product of urea and formaldehyde. ALPHONSE GAMS and GUSTAV WIDMER (to Soc. anon. pour l'ind. chim. à Bâle). Can. 281,325, June 26, 1928. One mol. urea and 2 mols. neutral CH_2O are heated to 98° under a reflux condenser; a condensation product may be pptd. with H_2O and alc. in 17 hrs. When heating is conducted in a closed vessel, temp. and other conditions being equal, the same degree of condensation is reached after $3\frac{1}{2}$ hrs. The product is useful for lacquers and impregnating agents. Cf. C. A. 22, 2818.

Condensation products of urea and formaldehyde. ALPHONSE GAMS and GUSTAV WIDMER (to Soc. anon. pour l'ind. chim. à Bâle). Can. 281,326, June 26, 1928. Waste (splinters, shavings) of hardened condensation products of urea and formaldehyde are heated at 120° for 2-3 hrs. with CH_2O of 36.5% strength. Thick soln. obtained is dild. in H_2O and heated with urea for 16 hrs. The mass is evapd. to a sirup and worked as though it were fresh condensation product. Cf. C. A. 22, 2818.

Condensation product of urea and formaldehyde. ALPHONSE GAMS and GUSTAV WIDMER (to Soc. anon. pour l'ind. chim. à Bâle). Can. 281,327, June 26, 1928. To a water-sol. condensation product from 1 mol. urea and 2 mols. CH_2O before or after concn., a quantity of urea is added and also a small quantity of acid and the mixt. is converted into a solid, clear or opaque final product at room temp. or by heating. Cf. C. A. 22, 2818.

Molded articles formed of particles of wood bonded with congealed sulfur. HARRY A. NOYES (to Texas Gulf Sulphur Co.). U. S. 1,675,576, July 3. Wood flour or sawdust, etc., bonded with S is used for making receptacles or other rigid molded structures.

Adsorbent material. LURGI GES FÜR WARMETECHNIK. Brit. 280,505, Nov. 11, 1926. An adsorptive agent for sepg. gases, decolorizing liquids or for other uses comprises fine dust or the like which may be subjected to selective sepn. by baffles, wet sepn., "cyclonic" or centrifugal treatment or elec. pptn.

Brake lining. ISADOR J. NOVAK (to Raybestos Co.). U. S. 1,667,842, July 17. Asbestos fiber is incorporated with a solid residue obtained from the heat treatment of a mixt. of water gas tar and petroleum oil (which may be heated to about 230° to obtain this residue).

Paint remover. OTTO L. FLÜGEL. U. S. 1,676,642, July 10. See Can. 269,704 (C. A. 21, 2380).

Laminated sheets formed of cardboard or similar material. JOHN D. CARTER. U. S. 1,676,727, July 10. Water-resistant plies such as cardboard or veneer are united by reaction products of alk. Na silicate soln. and CaCO_3 .

Fiber board for making cans or other receptacles. DONALD G. MAGILL (to American Can Co.). U. S. 1,676,617, July 10. Fibrous stock is impregnated with a mixt. of paraffin 90-75 and Montan wax 10-25 parts, which has a m. p. above the theoretical mean m. p. of the components of the mixt.

Coloring photographs or other materials. OTTO S. MARCKWORTH. U. S. 1,676,730, July 10. A photograph or other material to be colored is preliminarily treated with a wax emulsion which serves to facilitate blending the colors by heating and artists' colors or other suitable coloring material is then applied.

Sensitized screen for stencil process work. GLEN I. KEEL. U. S. 1,675,561, July 3. A gelatin dichromate compn. or other sensitizing soln. is applied to the surface of silk or other suitable fabric and a design is printed on the surface thus prepd. through a negative on which the desired design has been opaqued; the sol. materials are washed off and a lacquer is applied to one side of the screen and then removed from about the design formed from the non-sol. material by applying a thinner and washing through the screen from the other side.

Fire-extinguishing substances. EXCELSIOR FEUERLOSCHIGERATE A.-G. and O. TREICHEL. Brit. 280,543, Nov. 15, 1926. CO_2 and CCl_4 are used together; the CO_2 as used solidifies to snow-like form in mixt. with the CCl_4 and the snow-like mixt. is projected on a fire to be extinguished. A "Daniell" cock may be used for effecting admixt. and projection.

Apparatus for extinguishing fires by use of a fire-extinguishing powder carried by cooled exhaust gases from an internal-combustion engine. CORNELIUS SZILVAY. U. S. 1,677,875, July 17.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

Silica glass. HENRI GEORGE. *Bull. soc. encour. ind. nat.* 127, 373-408 (1928).—G. gives the history of silica glass, and its mechanical, optical, chem. and insulating properties. He discusses its manuf. and especially describes in detail a new process of manuf. which has considerably lowered the price of the product. L. B. MILLER

Beryllium glass. CHI FANG LAI AND ALEX. SILVERMAN. Univ. of Pittsburgh. *J. Am. Ceram. Soc.* 11, 535-41 (1928).—Over 80 different glasses were studied, in which BeO replaced the usual CaO or MgO. Be glasses are somewhat more refractory than Mg or Ca glasses. Annealing is apparently not difficult. Be glass shows lower d. than Ca or Mg glass. The hardness of Be glass is much greater than that of Ca glass and a little greater than that of Mg glass, lying between 6.2 and 6.7. The n is slightly above that of Mg glass but much lower than that of Ca glass. Transmission of ultra-violet light is good. Be glasses warrant further study. C. H. KERR

Window glass transmitting ultra-violet rays. ALFRED SALMONY. *Chem.-Ztg.* 52, 269-70 (1928).—Several special glasses and their uses in schools, greenhouses, etc., are discussed. Slight impurities may spoil the transmitting power of a glass for the shorter wave lengths of light. Some of these glasses may readily be blown into elec. bulbs for ultra-violet treatment. H. F. K.

A system of college education in ceramic technology. H. F. STALEY, K. TURK AND H. D. CUSHMAN. Comm. on Education, Enamel Union, Am. Ceram. Soc. *Bull. Am. Ceram. Soc.* 7, 190-202 (1928).—Curricula are discussed. C. H. K.

American Ceramic Society. Report of Committee on Standards. A. S. WATTS, et al. *J. Am. Ceram. Soc.* 11, 531-534 (1928).—A very comprehensive report, covering definitions, specifications, testing methods, descriptions of app., etc. C. H. KERR

Chemical control of feldspars. F. P. KNIGHT, JR. *J. Am. Ceram. Soc.* 11, 560-70 (1928). A discussion of the importance of control in mfg. processes. Some methods are given. C. H. KERR

The moisture of clay. TSURUJI OKASAWA. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 199-236 (1928).—In contradistinction to the ideas generally accepted, O. thinks that moisture is really H_2O entering into certain chemical combinations besides the recognized constitution of clay. A. L. HENNE

The development of the German brick industry. O. WITTE. *Tonind. Ztg.* 52, 753-5 (1928). H. G. SCHURECHT

Manufacture of paving brick. H. AVENHAUS. *Tonind. Ztg.* 52, 629-31, 674-6, 713-5 (1928). H. G. SCHURECHT

Modern trend of design for pottery plants. H. S. JACOBY. *Bull. Am. Ceram. Soc.* 11, 184-90 (1928). C. H. KERR

The requisite consistency of a casting slip. W. L. SHEARER. Rutgers Univ. *J. Am. Ceram. Soc.* 11, 512-59 (1928). C. H. KERR

Raw yellow glazes for terra cotta, and development phenomena. L. R. SQUIER. *J. Am. Ceram. Soc.* 11, 584-6 (1928).— TiO_2 , $BaCrO_4$ and U_3O_8 were tried with (a) an Albany slip-Cornwall stone glaze, and (b) a Bristol glaze. CaO, MgO or an improper amt. of ZnO should not be used with U_3O_8 to obtain yellow. BaO and a certain % ZnO, dependent upon the amt. of U_3O_8 and the compn. of the glaze, are advocated to give intense yellows in modified Bristol glazes. CaO and MgO appear to act as catalysts for the reduction of yellow and orange U oxide to greens and grays, at high temps. CaO and ZnO affect TiO_2 in glazes in the same way that U_3O_8 is affected. C. H. KERR

The problem of printed tableware. MARION L. FOSDICK. *Bull. Am. Ceram. Soc.* 7, 171-3 (1928).—A description is given of decalcomania work. C. H. KERR

Metal-polishing properties of stones in connection with their chemical and mineralogical composition and structure. V. V. ARSHINOV, B. YA. MERENKOV AND F. ANOSOV. *Trans. Inst. Econ. Mineral. Met. (Moscow)* 1928, No. 38, 1-30.—Hard stones are not suitable for removal of the surface inequalities of metals, in particular of Cu, since they soon become covered with Cu and thus lose their polishing effect. A slight amount of clay in the stone contributes to fine polishing, but an excess of it decreases the polishing capacity. British and Russian polishing stones have been examd. "Fine Polishing Block" (Scotch) was dark brown, very compact, non-hygroscopic, and of moderate hardness; its principal ingredients were quartz and mica. "Bluestone-Fine" (Scotch)

was gray, slightly porous and water-absorbing; its principal constituents were quartz and mica. The Russian stones, which were mined in the environs of Krivoi-Rog, were in quality much like the Scotch species "Tam O'Shanter" and "Bluestone-Fine." One of them was a phillite; it was compact, dark gray and of fine texture. The principal mineralogical constituents of the latter were 61% mica (35% of which was of the muscovite variety) and 37% quartz; its chem. analysis was: SiO_2 64.32, TiO_2 0.64, Al_2O_3 21.37, Fe_2O_3 and FeO 2.52, MnO 0.34, MgO 1.56, CaO 0.60, Na_2O 1.42, K_2O 4.85, loss on ignition 3.09%. Another Krivoi-Rog polishing stone was a black and fairly compact slate which consisted of quartz 49.5, mica 44 (26% of which was muscovite), coal-like substance 5, other minerals 1.5%. Its chem. compn. was: SiO_2 67.06, TiO_2 1.02, Al_2O_3 15.84, Fe_2O_3 and FeO 0.72, MnO 0.00, MgO 0.48, CaO 0.59, Na_2O 0.59, K_2O 2.94, V_2O_5 0.04, Cr_2O_3 0.02, loss on ignition 11.26%. BERNARD NELSON

Slagging of refractory materials [fireclay]. H. SALMANG. *Stahl u. Eisen* 47, 1816-20 (1927).—The action of the various constituents of metallurgical slags on crucibles made of a high-grade fireclay contg. SiO_2 56.52, ($\text{Al}_2\text{O}_3 + \text{TiO}_2$) 40.79 and Fe_2O_3 2.42% has been examd. at temps. up to 1600° . Ferrous and manganous oxides and the fluid basic silicates derived from them are extremely corrosive towards fireclay above 1100° , while CaO and MgO have a rapid slagging action above 1500° . The rate of corrosion decreases with increasing acidity of the slag, and viscous slags are much less reactive than the more fluid slags; thus orthoclase feldspar has practically no action on the clay at 1600° . Ca phosphate dissolves fireclay almost as rapidly as CaO does at 1500° . B. C. A.

Reflection from glass (AMY) 2. The use of α -hydroxyquinoline for the chemical analysis of silicates (ROBITSCHKE) 7. Reversible regenerative open-hearth furnace [for manufacture of glass] (U. S. pat. 1,675,588) 9.

Apparatus for feeding charges of molten glass. BRITISH HARTFORD-FAIRMONT SYNDICATE, LTD. AND T. WARDLEY. Brit. 280,611, June 18, 1926.

Apparatus for feeding separate charges of molten glass. ENOCH T. FERNGREN (to Hartford Empire Co.). U. S. 1,677,436, July 17.

Apparatus for feeding mold charges of molten glass. KARL E. PELIER (to Hartford-Empire Co.). U. S. 1,675,819, July 3.

Apparatus for delivery of unit charges of molten glass. HARVEY H. DEULEY. U. S. 1,677,275, July 17.

Continuous tank furnace for melting glass. CHAUNCEY F. FRAZIER. U. S. 1,675,542, July 3.

Melting glass-forming materials in a shaft furnace with a flame adjacent the bottom of the shaft. KURT KUNZEL. U. S. 1,676,267, July 10. An app. is described.

Heat-resistant borosilicate glass. LUDWIG HOCHSTEIN (to E. T. Brown). U. S. 1,676,331, July 10. A glass having a coeff. of expansion of approx. 0.0000017 comprises SiO_2 80-90, B_2O_3 7-15, Al_2O_3 1.5 and ZrO_2 1.5%.

Sheet glass. GEORGE H. HARVEY (one-half to Edward A. Lawrence). U. S. 1,676,027, July 3. A film is formed on the surface of a body of molten glass by treating it with a spray of moisture and this film is then withdrawn from the bath in sheet formation; the sheets thus formed are of substantially uniform thickness.

Making sheet glass reinforced with wire. WALTER COX and ARNO SHUMAN (to Pennsylvania Wire Glass Co.). U. S. 1,676,772-3, July 10. Mech. features.

Plate-glass-rolling apparatus. LEE SHOWERS (to Pittsburgh Plate Glass Co.). U. S. 1,676,056, July 3.

Apparatus for forming plate or sheet glass. L. VON REIS (to Naamlooze Venootschap Mij tot Beheer en Exploit van Octrooien). Brit. 280,533, Nov. 10, 1926.

Apparatus for making sheet glass by rolling. SOC. ANON. DES MANUFACTURES DES GLACES ET PRODUITS CHIMIQUES DE SAINT-GOBAIN, CHAUNY, ET CIREY. Brit. 280,582, Nov. 15, 1926.

Apparatus for making fire-polished sheet glass. CHARLES J. JORDAN (one-fourth to Rudolph G. Schaub). U. S. 1,677,095, July 10.

Apparatus for applying a rotating flame to glass to be worked. GEORGE A. MILLAR (to Cooper Hewitt Electric Co.). U. S. 1,676,796, July 10.

Apparatus (with a set of movable gas jets) for working hollow glassware. ROY D. MAILEY and WILFORD J. WINNINGHOFF (to Cooper Hewitt Electric Co.). U. S. 1,676,795, July 10.

Apparatus for manufacture of bottles or other glass hollow ware. GUGLIELMO DI RENZIS. U. S. 1,676,981, July 10.

Apparatus for molding tumblers or similar glassware. VIRGIL O. CORNWELL (to The Federal Glass Co.). U. S. 1,675,971, July 3.

"Crackled" glassware. DAVID L. MIDDENDORF (to The Federal Glass Co.). U. S. 1,675,951, July 3. A fluid such as atomized water is projected against a glass blank under such regulated conditions as to produce a crackled effect in the finished article without altering the temp. sufficiently to interfere with proper shaping. U. S. 1,675,952 specifies projecting a fluid such as water on the exterior of a mold to maintain the interior of the mold at a temp. which will produce a crackled effect on the molded glass.

"Antique" surfaces. RAYMOND J. GREENE (to The Gem Clay Forming Co.). U. S. 1,677,716, July 17. In forming back walls of radiant gas heaters or other articles of clay mixed with Mg silicate or the like, a slip contg. an oxide such as Sb oxide is applied to the surface of the article and the latter is fired so that the oxide combines with the Mg silicate to eat into the surface of the clay article. Cr oxide may also be used as a coloring.

Kiln drying ceramic ware. THOMAS DOWNS. U. S. 1,677,818, July 17. Air is circulated upward about the sides and over the crown of the kiln, and control and regulation of the relative circulation about and through the kiln are effected so that "sulfuring" of the ware is avoided. Structural features are described.

Rack for supporting ceramic products during heating in kilns, etc. THEODORE C. PROUTY and WILLIS O. PROUTY (to American Encaustic Tiling Co., Ltd.). U. S. 1,676,799, July 10.

Baking refractory linings in crucibles. FRANZ STÖHR. U. S. 1,675,735, July 3. In baking linings which may be formed of magnesite within crucibles which are open at one end and have a tap hole at the other end, the open end is provided with a temporary closure and through an opening in this closure a jet of flame is projected; combustion products are vented through the tap hole of the crucible.

Rubber-bonded abrasive articles. PEIR JOHANSON and DUANE E. WEBSTER (to Norton Co.). U. S. 1,676,190, July 3. In forming grinding wheels or other abrasive articles, a rubber bond is used together with an admixt. of wax such as beeswax which serves as a modifying agent and decreases the hardness of the bonded article after vulcanization.

Sagger. JOSEPH A. JEFFERY (to Champion Porcelain Co.). U. S. 1,677,452, July 17. Sagers are formed of SiC covered by a refractory alumina-silica compn. such as andalusite which does not change materially in vol. from the green state in which the compn. is applied when fired to a high temp. The layer is of sufficient thickness that it would be injured by any disproportionate changes in vol. relative to the SiC.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Japanese cement industry. C. R. PLATZMANN. *Zement* 17, 222-3(1928).

H. F. K.

Crystal phases in technical portland cement clinker. II. A. GUTTMANN and F. GILLÉ. *Zement* 17, 296-9(1928); cf. C. A. 22, 2042.—Photomicrographs of thin sections of clinker show crystals with zones indicating the possibility of mixed cryst. structure for some of the hydraulic components of cement.

H. F. K.

Study of a method for testing concrete in the field. C. A. WIEPKING. *Proc. Am. Concrete Inst.* 24, 212-39(1928).—The prepn. of materials, proportioning, mixing, molding, curing, testing and computing the results are discussed.

J. C. WITT

A method for predicting concrete strengths with increased precision. HERBERT J. GILKEY. *Proc. Am. Concrete Inst.* 24, 149-78(1928).—The quality of concrete, regardless of what particular test may be used as its measure, is influenced by many factors that may be more or less arbitrarily classified as major and minor. The major factors are (a) the cement, (b) ratio of mixing water to the cement, (c) ratio of voids to the cement, (d) effective age, i. e., period of moist curing, (e) curing temp. The minor factors are (f) kind, quantity and grading of aggregates, (g) time of mixing, and (h) incidental factors and personal equation. These same factors may be classified, also, as systematic (b, c, d, e, g) and chance (a, f, h). The use of the method is recommended when it is desired to predict either the general quality or some specific property of concrete.

J. C. WITT

Influence of size of test pieces, their position in the original material, and the

different spans of pressure in the flexural strength of asbestos-cement slates. O. KALLAUNER. *Zement* 17, 275-6(1928).—Strips taken from various portions of the slates showed fairly uniform results. The size or the span had little effect on the flexural strength in kg./sq. cm. under the conditions maintained, whole slates being adaptable to the test. H. F. K.

Cement and concrete problems. V. BAHNER. *Zement* 17, 265-9(1928).—The relations of time to compression strengths of concrete and mortar mixes designed according to the water/cement ratio are shown graphically and discussed. H. F. K.

Weight per unit volume of portland cement. HAEGERMANN. *Zement* 17, 379-85 (1928).—The weight per vol. of finely powd. materials is affected by the size and shape of the container and by the method of filling it. For normal and early strength cements, resp., weights of 126.6 kg. and 120.2 kg. per 100 l. measure were obtained, the fineness of the latter cement reducing its wt. Detus with one vol. cannot be converted readily into wts. per other vols. App. for filling the measures is described. H. F. K.

Flow of concrete under sustained compressive stress. RAYMOND E. DAVIS. *Proc. Am. Concrete Inst.* 24, 303-35(1928).—Twenty-four $6 \times 24"$ concrete cylinders were loaded 640 lbs. per sq. in., and forty-five $4 \times 14"$ were loaded from 200 to 1200 lbs. per sq. in. Results indicate that the time-flow relation is affected by (a) cement ratio, (b) gradation of aggregate, (c) moisture conditions of storage, (d) age at time of loading and (e) magnitude of compressive stress. In a series of graphs, flows from 0 to 0.1% are shown. J. C. WITT

Measurement of the finest fractions in portland cement by use of the Wiegner sedimentary apparatus. HANS KÜHL AND JOSHIO TOKUNE. *Zement* 17, 256-61, 299-301(1928).—The app. used consists of a glass tube 1.57 m. long and 42 mm. diam. fitted with a side arm of small diam. extending from near the bottom of the tube to its top. This side arm is fitted with stopcocks at top and bottom. To the tube nearly filled with abs. alc. is added a definite weight of cement, usually 30 g. After carefully mixing the cement and alc. to obtain a uniform suspension the meniscus reading in the side arm is taken. During the settling of the suspended matter the fall of the meniscus is observed at definite intervals photographically. Applying Stokes' law for falling bodies the diam. of the particles remaining in suspension at any time may be calcd. The distribution of cements into particles of 60, 40, 25, 15 and 10 μ diam. are thus obtained from the graphically recorded sedimentation values. Reliable results are claimed for the method when temp. is controlled. H. F. K.

United States Government master specification for integral waterproof material (for use with portland cement mortar or concrete). Bureau of Standards, Circ. No. 360, 4 pp (1928). E. H.

Italian specifications for hydraulic cements and for structures of concrete and reinforced concrete. ANON. *Zement* 17, 337-41(1928). H. F. K.

Reinforced-concrete building regulations and specifications. report of Committee E-1 on reinforced concrete building design and specifications. F. R. McMILLAN, et al. *Proc. Am. Concrete Inst.* 24, 786-833(1928). J. C. WITT

Tentative amendment of standard specifications for concrete block and concrete building tile. report of Committee P-1 on standard concrete building units. C. L. BOURNE, et al. *Proc. Am. Concrete Inst.* 24, 834-51(1928). To this report is appended methods of tamping and feeding in manuf. of dry tamped concrete masonry units. J. C. WITT

Researches on concrete materials and on plain and reinforced concrete. report of Committee E-3 on research. H. F. GONNERMAN, et al. *Proc. Am. Concrete Inst.* 24, 745-76(1928).—The report is outlined as follows: researches on cement (constitution tests, vol. changes, effect of gypsum, humidity); researches on aggregates (mech. analysis, influence of iron content, soundness, moisture); researches on plain concrete (admixtures, curing, durability, mixing water, permeability, sea water, strength, temp., test methods, vol. changes, workability, yield); researches on reinforced concrete (arches, chimneys, culvert pipe, frames, slabs); suggested researches on concrete and related subjects (aggregates, plain concrete, reinforced concrete); references to papers and reports on researches published during 1927. J. C. WITT

Calculations of the raw [cement] powder using a mixture of different highly siliceous clays but keeping a constant silicate modulus. C. HELMHOLTZ. *Zement* 16, 1092 (1927). H. F. KRIEGER

Requirements of gravel as an aggregate for concrete.—report of Committee E-5 on aggregates. (Sub-committee on gravel.) R. W. CRUM, et al. *Proc. Am. Concrete Inst.* 24, 777-84(1928). J. C. WITT

Determination of the mechanical mixture of mortar and concrete. Ratio of ce-

ment to aggregate in the mix. V. RODR. *Zement* 17, 138-47(1928).—In a discussion of previous German methods of detg. the cement content of concrete it is claimed that an error is introduced by the liberation of sol. or colloidal SiO_2 from parts of the aggregate as well as from the cement. In sands this sol. SiO_2 is derived chiefly from the silt or loam. This effect may be reduced by dilg. the 1:3 HCl soln. to 1:9, whereby the sol. SiO_2 liberated is less than 0.1%. The procedure becomes: digest 10 g. finely ground sample with 100 cc. 1:9 HCl on the water bath, boil for 2 min., filter at once and wash the residue off into a beaker with 100 cc. 5% Na_2CO_3 soln. and boil for 2 min. Filter, combine the filtrates and det. the SiO_2 liberated by the usual methods. If the silt content is known to be small 1:3 HCl digestion may be employed. The found SiO_2 is calcd. to cement by using 22% as the SiO_2 content of cement. Since the water of hydration is about 20% of the set cement wt. this correction must be added if the % compn. of the concrete is to be stated in terms of the hydrated cement.

H. F. K.

Determination of mix of concrete. HEINRICH HART. *Zement* 17, 319-20(1928).—With reference to the preceding abstr. it is claimed that the method described is limited to quartz sand-gravel concrete whereas in practice the aggregates vary so greatly in compn. that the method will not apply generally.

H. F. K.

Workability symposium. *Proc. Am. Concrete Inst.* 24, 24-100(1928).—This symposium consists of the following papers on the workability of concrete: **A study of some methods of measuring workability of concrete.** GEORGE A. SMITH AND GEORGE CONAHEY. *Ibid* 24-42. **Cement as a factor in the workability of concrete.** P. H. BATES AND J. R. DWYER. *Ibid* 43-55. **Gradation and character of aggregates as a factor in workability.** A. T. GOLDBECK. *Ibid* 56-66. **Water as a factor in workability.** R. L. BERTIN. *Ibid* 67-9. **Workability means durability to the engineer.** R. W. ATWATER. *Ibid* 70-6. **What workability means to the contractor.** NELSON L. DOE. *Ibid* 77-82.

J. C. WITT

Better concrete. Do we mean it? NATHAN C. JOHNSON. *Proc. Am. Concrete Inst.* 24, 480-94(1928).—J. points out the possibility and need for improvement in present concrete practice. Both field research and lab. research demonstrate that better concrete and cheaper concrete are identical.

J. C. WITT

Concrete primer. F. R. McMILLAN. *Proc. Am. Concrete Inst.* 24, 495-535 (1928).—The primer is a series of 142 questions and answers which develop in simple terms the principles governing concrete mixts and show how a knowledge of these principles and of the properties of cement can be applied to the production of permanent structures in concrete. The divisions of the primer are cement, mortar and concrete; factors affecting the strength of concrete; problems of proportioning; production of durable concrete. An appendix gives 2 field methods for detg. the moisture in sand: (1) displacement with cylindrical container, and (2) drying to const. wt. with de-natured alc. In the second method, 500 g. of damp sand are placed in a pan and moistened with 100-200 cc. denatured alc. The alc. is ignited, and the sand is stirred to facilitate the escape of moisture.

J. C. WITT

Notes on the progress of some studies of the crazing of portland cement mortars. P. H. BATES AND C. H. JUMPER. *Proc. Am. Concrete Inst.* 24, 179-89(1928).

J. C. WITT

Crazing in concrete and the growth of hair cracks into structural cracks. ALFRED H. WHITE, VILHELM A. AAGAARD AND AXEL O. L. CHRISTENSEN. *Proc. Am. Concrete Inst.* 24, 190-201(1928).—Crazing is due mainly to the rather rapid evapn. of water from the surface of a rich cement mortar or concrete. It may be prevented by using lean mixts. and by keeping the moisture content of the concrete const.

J. C. WITT

Surface protection of concrete against corrosive waters. H. DUBIEL. *Zement* 17, 70-2(1928).—A general discussion of present methods.

H. F. K.

Water permeability of concrete. W. PETRY. *Zement* 17, 318-9(1928).—The report of a commission investigating some concrete structures subjected to H_2O under pressure includes the following factors governing water tightness: (a) Imperviousness is in direct relation to cement content. (b) Admixts. such as stone flour, lime, etc., do not alter the above relationship. (c) The d. of a concrete cannot be predicted from a statement of the content of mixing water without a knowledge of the particle size and the ratio of the quantities of sand and gravel. (d) Natural gravel and sand give a much denser concrete than do crushed materials. (e) Moist curing was better than air curing though the air-cured specimens sealed themselves quickly when exposed to water. (f) This sealing proved to be temporary as intermittent wet and dry treatment showed a return of the air-cured concrete to a pervious state between wettings. (g) The time of curing between 53 and 97 days had little effect. (h) When the self-sealing effect

is left out of account the permeability to water bears a simple relation to water pressure. (i) Surface treatment of pitch proved successful. (j) 2-3 cm. layers of 1:2 and 1:3 cement mortar were tight up to 10-15 m. H_2O . (k) Metal sprays made water-tight concrete up to 15 atm. pressure. H. F. K.

Chemical resistance of cement. CURT PRÜSSING. *Zement* 17, 385-7(1928).—The resistance of normal portland, slag and special cements to the attack of natural and artificial sulfate-contg. solns. is discussed. H. F. K.

Trend of portland and accelerated portland cement compositions. EDWIN C. ECKEL. *Eng. News-Rec.* 100, 617-8(1928).—It is shown by means of triaxial diagrams that trend in manuf. of cement is toward the production of tricalcium silicate. The early strengths of accelerated portland cement concrete, up to 6 months at least, are more than 25% in excess of portland cement concrete strengths. R. E. T.

The determination of the quantity of cement used in hydraulic concretes. DOMENICO MENEGHINI. *Ann. scuola ing. Padova* 2, 95-9(1926).—Finely pulverize a weighed sample (1-2 g. for cement; 10 g. for cement mixts.) and treat with 250-300 cc. of boiling water. Add 100 cc. of HCl (d. 1.05-1.06) and after the evolution of CO_2 has ceased heat the mixt. but do not allow to boil, wash by decantation with boiling H_2O and filter the washings through a Gooch crucible. Treat the residue with about 75 cc. of N $NaOH$ on the water bath at 80° . Decant this alk. liquor into the same filter previously used and wash the residue thoroughly with hot H_2O . The filtrate contains all the active silica derived from silicates that are attacked by this treatment. The silica is sepd. and weighed as SiO_2 and represents the so-called active silica. The method was controlled by detg. the active silica in fresh cement and in cement mixts. prepd. under various conditions and allowed to stand for various lengths of time. L. T. FAIRHALL

Influence of low temperatures and frost on the properties of quicksetting portland cement. A. GESSNER. *Zement* 17, 10-12(1928).—Quicksetting cements suffered relative reductions in compression and tensile strength much like normal portland cements. Because of their high early strength, they have a distinct advantage over normal cements in severely cold weather. H. F. K.

Rotary kiln and its development. N. C. KYRIACOU. *Zement* 17, 342-4(1928). H. F. K.

Influence of time and type of curing on the strength of asbestos cement slates. O. KALLAUNER. *Zement* 17, 99(1928).—The greatest increase in flexural strength comes in the early stages of curing. Combined moist and air curing conditions gave the highest strengths. Prolonged moist curing tended to produce "popouts." Very little gain in strength was found between 28 and 90 days. H. F. K.

Report of committee S-6 on concrete roads and pavements. W. M. ACHESON, et al. *Proc. Am. Concrete Inst.* 24, 852-3(1928). J. C. WITT

The hardening of silicated roads. M. R. FERRET. *Tech. sand. munic.* 23, No. 5, 111(1928).—Encouraging results were obtained by impregnating limestone with Na_2SiO_3 . The hardening effect is attributed to the pptn. under certain conditions of silica jelly which surrounds the stony particles with an insol. and resistant magma. The principal influence is probably absorption due to the finely divided solid particles. This action is favored by desiccation, dialysis and by CO_2 . C. R. FELLERS

Concrete paving-base control by bore tests. E. A. KEMMLER. *Eng. News-Rec.* 100, 660(1928).—The results of systematic concrete base control in Akron, O., are described. In the 5 yrs. during which the system has been developed the av. strength of the base has increased from less than 750 lbs. per sq. in. at 28 days to an excess of 2500 lbs. The av. cost per core, including lab. tests, is \$5.50. The strength curve demonstrates that the curing method employed, sprinkling with a hose, has not been successful, the peak strength occurring in October when conditions are most favorable for natural curing. The 1928 specifications provide for curing by ponding or covering with wet straw for 7-10 days. The 4-in. cores have not been found entirely satisfactory and 6-in. cores have been substituted. R. E. THOMPSON

Chemistry in road building. VON SKOPNIK. *Chem.-Ztg.* 52, 397-8(1928).—Outline of the control work done at the "Strassenbahnlaboratorium der Provinz Brandenburg." The method used for the analysis of mixts. of bitumen and tar by means of H_2SO_4 is summarized. The correction factor for the bitumen is about 4%. A. L. H.

Wall board patent history. JOSEPH ROSSMAN. *Paper Trade J.* 86, No. 22, 50-3(1928).—A review of U. S. patents, with brief abstracts. A. PAPINEAU-COUTURE

Use of petroleum and petroleum products for the preservation of wood. A. SAPOSHNIKOV AND B. KOPYTKOVSKI. *Neftyanoe Khozyaistvo* 11, 748-54(1926); *Chem. Zentr.* 1927, I, 2381.—Alkali salts of naphthenic acids (especially those of acids which be-

150–5°) kill the fungus, *Merulius lacrimans*, even when they are used in lower concn. than ZnCl_2 or NaF . Mold fungus, on the other hand, is killed only with higher concns. of naphthenic acid salts. A mixt. of NaF and naphthenic acid salts (equal wts.) is recommended for the preservation of wood. Another active preserving agent is prepd. by mixing creosote oil (from coal tar) with petroleum distillates, *e. g.*, with gas oil or light lubricating mazout (Engler mazout). For each 1 vol. of creosote oil, 3 vols. of petroleum product are used.

C. C. DAVIS

The mechanical and physical laboratories for testing lime and cement at the Polytechnic Institute at the University of Grenoble (DEJEAN) 2. Rubber sheet material with fibrous backing (U. S. pat. 1,677,284) 30. Producing granules from steatite or similar materials (U. S. pat. 1,677,701) 18.

BOLOMEY, J.: *Durcissement des mortiers et bétons*. Paris: Rouge et Cie. Paper, Swiss F. 2.

FORESTIER, V.: *Agenda Dunod 1928. Béton armé*. Coll. Agendas Dunod. Paris: Dunod. 356 pp. F. 17.

Cements high in alumina. ALEXANDER HASSELBACH (to G. Polysius). U. S. 1,677,182, July 17. A raw cement mixt. is introduced into a rotary kiln together with a small proportion of fluorspar and burning is effected at a temp. below the m. p. of similar mixts. not contg. fluorspar.

Cement mixtures, etc. H. E. DOUGHTY. Brit. 280,813, June 7, 1927. Mixts. of cement, plaster, gypsum, etc., with sand, coloring agents and the like are ground and the fine particles are drawn off by air flotation *in vacuo*. Ingredients such as Na silicate, alumina, silica or gypsum may be added during the process.

Mixture of cement and fiber for making slabs, etc. J. S. HANCOCK and W. H. MACMENIGALL. Brit. 280,456, May 30, 1927. An app. is described in which the dry material, after a preliminary mixing, is fed to a breaker with a stream of water and the wet mixt. is then delivered to a head box with more water obtained from the backwater of a forming machine to which the wet mixt. is supplied.

Concrete building blocks. HARMON S. PALMER. U. S. 1,676,153, July 3. Layers of sugar cane fiber are secured to the sides of concrete blocks and serve to retain the block in shape before setting and also serve as an insulation.

Internal curved baffle system for rotary kilns for cement making, etc. FRITZ LUTHER (to G. Polysius). U. S. 1,675,717, July 3.

Rotary kiln and cooler for cement manufacture. POVL T. LINDHARD (to F. L. Smidth & Co.). U. S. 1,675,416, July 3.

Road surfaces. R. H. KING. Brit. 280,819, June 16, 1927. Soil forming the road surface is burned *in situ* to harden it. A wearing surface may be formed by fusing the soft earth and mixing it with bitumen. Various details are given and an app. is described.

Street pavements. AUGUST E. SCHUTTE (to Warren Bros. Co.). U. S. 1,677,600, July 17. A foundation is covered with a thick layer of mineral aggregate and bitumen which is rolled, tamped and consolidated until cold and solid and incapable of being further distorted; the superficial portion of this layer is then melted and a thin wear-resisting layer is placed upon it, followed by further rolling.

Porous clinker for use in making building blocks, concrete, etc. E. I. LINDMAN. Brit. 280,567, Nov. 10, 1926. Clays, rocks or the like which expand on heating are heated by burning in air after crushing and mixing with fuel. Various details are specified.

Veneer sheets for covering walls, etc. J. BRÜNING & SOHN, A.-G. Brit. 280,785, Feb. 25, 1927. Embossed plywood veneer sheets of the thickness of paper are prepd. by first thickly coating the back with glue or paste contg. a hardening agent, *e. g.*, CH_3O , ZnO or waterglass, and then embossing. The back is moistened and pressed onto a wall to secure it to the latter.

A. C. FIELDNER

Analysis of solid fuels. I. Sampling, proximate and ultimate analysis. A. A. POTTER AND H. L. SOLBERG. *Power* 67, 1094–6(1928).—The processes of sampling and of making a proximate analysis are described. II. Determination of heating

value. *Ibid* 68, 105-7.—A review of methods for estn. of ultimate compn. when proximate analysis, heating value and S content are known. D. B. DILL

The production of smokeless domestic fuel. JOHN ROBERTS. *Gas J.* 183, 42-3 (1928).—An historical review of process development. F. S. GRANGER

Purification of benzene for motor fuel. F. T. HATSWELL. *Gas World* 88, Coking Sect., 11-4 (1928).—Crude benzene, after washing with dil. acid, is treated, for 1 hr. at 50-60°, with an intimate mixt. of an active form of $\text{Fe}_2(\text{SO}_4)_3$ and an absorbent material. This transforms the objectionable impurities into products which are absorbed. It is then filtered, neutralized and distd. The losses are much smaller than with the usual acid washing, with which the costs compare favorably, and the product, though unable to pass the acid tests, is stable, free from gumming materials and S, and performs better in the engine than a normal high-grade benzene. F. S. GRANGER

Wood as a fuel. L. A. WANDERLEY. *Bol. soc. chim. S. Paulo* 1, 73-7 (1928).—The heat of combustion of 10 different kinds of *Eucalyptus* varied between 4744 and 4655 cal. or an av. of 4680 cal. Five other typical Brazilian trees gave practically the same results. The value of the wood as a fuel depends almost entirely on the water content and on the sp. wt. R. D. BUMBACHER

Drying wood refuse for fuel. E. V. AHARA AND R. C. WIREN. *Pulp Paper Mag. Can.* 26, 377-9 (1928).—A description of the Nordstrom drying tower installed at the Wisconsin Rapids mill of the Consolidated Water Power & Paper Co. and of its performance, which was found to agree with the constructor's guarantee within 5%. One of its outstanding features and merits is that it works at very nearly 100% efficiency with gases at as low a temp. as 193° F. A. PAPINEAU-COUTURE

Coals of the Cheremkhov district. G. I. STADNIKOV AND E. E. IVANOVSKII. *Papers Karpov Chem. Inst. Bach. Memorial Vol* 1927, 198-205.—Cheremkhov coal mines are 80 km. West of Irkutsk and form a part of the richest coal deposits, estd. at 150 billion tons of solid fuel. The characteristic feature of the former is that their S content increases from 0.2 to 6.0% the deeper the mine. Analyses of 5 samples of these coals are given. BERNARD NELSON

The bitumens in Hokkaido coals. KWAN TAWADA. *J. Fuel Soc. Japan* 7, 11-7 (English Section) (1928).—The bitumens of Hokkaido coals were studied with a view to finding a theoretical method for obtaining good coke. The bitumens were extd. with benzene and pyridine by Fischer's method. The benzene and pyridine exts. were sepd. into oily and solid bitumens by the methods of Wheeler and Bone and of Wheeler, resp. The benzene and the pyridine exts. are similar in quantity and character. The petr. ether-sol. fraction and the oily bitumen resemble each other and may be regarded as hydrocarbon; the ether-sol. and the alc. ether-sol. solid bitumens may be resinous substances; acetone-sol. bitumen and also the solid bitumens insol. in acetone, alc. and ether resemble humus substance. The caking and swelling properties of exts. were studied to det. which theory, Fischer or Bone, can be applied to Japanese coal. The Muck test shows that the caking and swelling properties of each fraction of solid bitumen are stronger than those of oily bitumen, alc. sol. and ether-sol. solid bitumen have the strongest caking power while alc.-insol. and ether-insol. solid bitumen is inferior to others in this respect. This conclusion appears to be well in accord with Bone's results. The results obtained in regard to the swelling property coincide perfectly with Fischer's; that is, oily bitumen does not swell, while solid bitumen almost always swells. The softening and decompn. temps. of the exts. were studied by the method of Audibert. Almost all constituents of coal soften and decompose between 350° and 400° at any rate of heating. The decompn. points of the benzene exts. are arranged in the order of extd. residue, solid bitumen, oily bitumen; those of the pyridine exts. are in the order α , γ , β compd. The softening points are almost in the same order as the decompn. points. Audibert's principle, that if T_s (the softening temp.) is lower than T_p (the decompn. temp.) the coal can be coked, and if $T_s > T_p$, it is difficult to obtain good coke, was confirmed. The problem of coal blending is discussed, but no scientific theory is proposed. FRANK I. NAKAMURA

Bituminous coal as water-gas generator fuel at Detroit. HENRY FINK. *Gas Age-Record* 61, 777-8 (1928).—The Tireman Ave. water-gas plant of the Detroit City Gas Co. has been operated on 100% bituminous coal since Nov. 1925. Only slight changes were necessary. Elkhorn coal is used with a 4 min. cycle making a 526° B. t. u. gas of 0.630 to 0.650 sp. gr. As compared to oven coke, 4 in. \times 6 in. coal has the following advantages: lower fuel requirement, higher oil efficiency, less screening loss, lower clinkering cost, lower cost of maintaining generator linings and less deterioration of back run pipes and valves. LESLIE B. BRAGO

Bituminous coal as water-gas generator fuel. GEORGE H. PARK. *Gas Age-*

Record 61, 849-50, 853-4(1928); cf. preceding abstr.—A method of utilization of 100% coal in water-gas generators with expense figures from the Charleston plant of the South Carolina Power Co. Straight water-gas plants, with some few exceptions, could profitably use 50 to 60% bituminous coal as generator fuel. **LESLIE B. BRAGG**

Coal liquefaction and its importance in world economy. H. BRUCKMANN. *Mining J.* 160, 69-70, 94, 116(1928).—B sketches Germany's oil needs and summarizes the products and yields of high- and low-temp distn. The early studies of Bergius are described and the general features of the process outlined. The products of hydrogenation of 1000 kg. of coal are 650-700 kg. of oil, 230 kg. of pitch residue and 120 kg. of gas and loss. The oil on distn. gives 31% motor fuel, 41% Diesel engine oil, 16% fuel oil and 12% lubricating oil. B. figures costs at 71 marks per 1000 kg. treated, from which the products at German prices conservatively yield 141 marks or a surplus of 70 marks per 1000 kg. of coal. A plant to produce 50,000 tons of coal oil annually costs about 10 million marks. This means a conservative profit of 25% on the capital cost of the plant. This would be increased for brown coal due to cheaper mining costs. B. suggests yearly construction of plants of 200,000 tons oil capacity. Thus up to 1932 construction will keep pace with the increase in demands, for a few years equl. will be established; after this importations will gradually decrease. To reach independence, Germany will require an investment of 500 million marks. **ALDEN H. EMERY**

Liquid fuel from coal. DAVID BROWNLIE. *Gas Age-Record* 61, 879-81, 884, 913 5(1928). The subject is carefully reviewed with particular emphasis being laid on low-temperature carbonization, 30 of the more important processes being discussed in particular. **LESLIE B. BRAGG**

The Bergius process for the liquefaction of coal. HENRY O. ASKEW. *New Zealand J. Sci. Tech.* 9, 321-31; 10, 1-16(1928). A summary of the developments of coal liquefaction published between 1924 and 1927 with a bibliography of the literature and patents consulted. Plant details, operation, costs and chem reactions occurring in the process are reviewed. **A. S. CARTER**

Blending of coals before extraction of gas. A. THAU. *Gas u. Wasserfach* 69, 970 1(1926), *Chem. Zentr.* 1927, 1, 825-6.—A review of recent developments by various investigators. **C. C. DAVIS**

Diesel engine performance on oils obtained from the low-temperature carbonization of coal. J. S. BROWN. *J. Roy. Tech. Coll. (Glasgow)* 1927, No. 4, 76-84.—The behavior of oils from the low temp. carbonization of coal has been compared with that of creosote oils (I) from coal and petroleum oil, (II) from shale, when used in a single-cylinder Mirreles Diesel engine, bore and stroke 12 X 18.25 in., at 200 r. p. m., compression 470 lb. per sq. in., water jacket temp. at 135° F. Three carbonization oils were tested: Maclaurin oil (III), from a vertical retort heated by partial combustion, L. and N. oil (IV) from a rotary inclined retort heated by inert gas, and Turner oil (V) from retorts directly heated internally with superheated steam. No operation records could be obtained on III because of its high viscosity which rendered fuel injection impossible under usual conditions. The thermal efficiency of the engine with I, II, IV and V was the same, av. 0.5 lb. fuel per b. h. p. hr. (18,500 B. t. u. basis). At low power output V did not preignite, IV did occasionally, but IV and V were both better than I though not quite as good as II. Starting tests showed that none of the oils had the qualities of II for starting with a cold jacket (62° F.). **A. S. CARTER**

Dvorkovitz system of low-temperature carbonization demonstrated. A. C. BLACKALL. *Combustion* 18, 180 1928.—A short discussion. **LESLIE B. BRAGG**

A new British low-temperature carbonization process. DAVID BROWNLIE. *Gas Age-Record* 62, 39-40, 48(1928); cf. *C. A.* 22, 1667.—The Winsor process is described. It consists essentially of a circular tunnel oven, very similar to the circular kiln used for pottery and ceramic ware. An installation with a throughput of 50-60 tons of coal per day is to be built at Erith, near London. It is to have an over-all outside diam. of 44 ft. 2 in., with the tunnel portion 11 ft. 5 in. wide, leaving a hollow center portion 28 ft. 4 in. diam. Ninety vertical, cast iron retorts, 5 ft. 6 in. high, 4 ft. 6 in. long and 8 in. wide are fixed on a traveling cast iron floor, driven by gearing and running on ball bearings. The tunnel is heated externally, the hot gases passing through about half of the total periphery counter-current to the retorts, which are mechanically charged and emptied. The charge is to be heated to a max. temp. of 500-600° and a cycle is to be about 6 hrs. **LESLIE B. BRAGG**

A British carbonization test on a rotary retort. W. HAMILTON GORDON. *Combustion* 10, 44, 46(1928).—A discussion of a "Fusion" rotary retort test carried out by the Brit. Fuel Research Board. **LESLIE B. BRAGG**

Dry distillation at low temperatures of the coals and the bogheads of the Moscow

district. A. P. SHAKIHO. *J. Chem. Ind. (Moscow)* 4, 324-6(1927).—The coals of the Moscow district are extremely rich in ash and S, are very hygroscopic and yield a coke which does not agglomerate and is easily alterable on keeping. S.'s investigation tends to show that the most rational utilization of these coals consists in distg. them at low temps. The semicoke obtained from the coals is a powder which is less hygroscopic than the coals and contains less S, but more ash; its high volatile matter content enables it to burn well, and its calorific capacity is higher than that of the coals from which it was derived. Primary coal tar is obtained in small quantities, has a high S content, a small paraffin content and a relatively high calorific capacity. Little of primary gas is obtained and the latter requires purification before it can be used as lighting gas. The bogheads are much more interesting than the coals, as they give, on dry distn. at low temps, 45% of a valuable primary tar. The semicoke obtained from the bogheads has little interest. The primary gas obtained from the bogheads had a high calorific capacity and is valuable.

BERNARD NELSON

The growing importance of coal as a raw product. THOMAS S. BAKER. *Combustion* 18, 191-3(1928).—A discussion.

LESLIE B. BRAGG

Pulverized coal—a short comparison of American and English practice. GEO. F. ALLIN. *Fuel Econ. Rev.* 7, 46-7(1928).—Differences in data showing results of using powdered coal are ascribed to (a) the greater H₂O content of dried English coal, (b) the greater absorptive power of the latter, (c) the greater av. humidity of the English atm., (d) the necessity for more thorough drying in Great Britain, and (e) the greater hardness of English coal, and therefore difficulty of pulverizing it. Even with these disadvantages the use of powdered coal is recommended.

W. C. EBAUGH

Some observations on coke quality in relation to the size, mixture and storage of the coal. HS. DERINGER. *Monats. Bull. Schweiz. Ver. Gas Wasserfach.* 8, 121-4(1928).—The investigation was carried out on a large scale under industrial conditions, on lower Silesian coal dust, pea and nut and Ostrau-Salm small coal. The coal was coked in a chamber oven in continual operation. Details are lacking. The results are expressed in terms of sieve tests in which 300 kg. samples of coke were passed through a series of screens and the percentages passing through each screen were plotted against the mesh. The coke is valued according to the predominance of larger sizes. On this basis, the coke from the dust coal was very superior to that from the nut or Ostrau coals, because of the fluxing action of the dust on coking. For the same reason, the predominance of larger pieces in the coke from mixts. of the coals increased with the proportion of dust coal. The dust and Ostrau coals mixed before coking yielded a coke showing a somewhat better sieve test than a corresponding mixt. of the cokes obtained from the same coals separately. After several months storage, these coals individually yielded definitely more broken-up cokes than the same coals fresh. But with a mixt. of the 2, the effect of storage was very slight.

F. S. GRANGER

Economic and engineering survey of the gas industry. WALTER C. BECKFORD. *Gas Age-Record* 61, 351-4, 393-6, 400(1928).—A discussion of the problems confronting the gas industry. Among these is the possible use of butane and propane, obtainable from natural gas casing head operations, for the enrichment of lean gases.

LESLIE B. BRAGG

Gas dehydration. E. F. COFFMAN. *Gas Age-Record* 61, 507-9(1928).—Tests made on the distribution system of the Public Service Gas Co. of N. J. showed that the gas leaving the governor on a 50 lb. main line had a dew point of 31.5°. On passing through a water-sealed holder the dew point rose to 66° but with a layer of oil 1.7 in. deep on the water the dew point rose only 2.5°. Repairs to meter diaphragms alone cost 1.1 cents more per 1000 cu. ft. with wet gas than with partially dehydrated gas and it is estd. that dehydration will save from 1½ to 2½ cents per 1000 cu. ft.

LESLIE B. BRAGG

Calcium chloride for gas drying. CHARLES COOPER. *Gas Age-Record* 61, 477 (1928).—Polemical versus Sperr (C. A. 21, 1535) and Bragg (C. A. 22, 1670) with respect to the corrosion of equipment as a result of the use of CaCl_2 for gas drying. L. B. B.

Tables for determining specific gravity and heat value of gases. FRED M. REITER. *Gas Age-Record* 61, 469-71 (1928).—A set of tables is given by means of which the sp. gr. and heat value of a gas may be easily computed from the gas analysis. L. B. B.

Waste heat recovery. MAJOR W. GREGSON. *Gas Age-Record* 61, 397-400; *Engineering* 125, 241-3, 272-3 (1928).—A discussion with test data from waste-heat recovery plants on gas-retort settings. The normal gas works can meet the whole of its power and process requirements by means of waste-heat steam. L. B. B.

Gas analysis solutions. F. M. REITER. *Gas Age-Record* 62, 6, 8-9 (1928).—Directions are given for the making up of gas analysis solns for the absorption of CO_2 , O_2 , illuminants, CO , C_2H_6 , $(\text{CN})_2$, C_2H_4 , NH_3 , CS_2 , H_2S and other gases. L. B. B.

The removal of phenol wastes from gas plants. LOUIS SHNIDMAN AND LINN B. BOWMAN. *Gas Age-Record* 61, 626-8, 634 (1928).—A summary of a study of the action of phenol wastes upon sanitary sewage and upon sludge digestion in Imhoff tanks. NH_3 still waste can be added to sewage in the ratio of 1-2000 without ill effects on the operation of the Imhoff tanks. Only a small quantity of the phenols is destroyed in this manner but trickle filters or activated sludge apparently destroys the phenols.

The Cottrell electrical precipitation processes. N. W. SULTZER. *Gas Age-Record* 61, 505-6, 516 (1928).—A discussion of the use of elec. precipitators for detarring gas. Tar, oil fog and any condensed water vapor is removed with an efficiency of over 95%. There is considerable saving due to a longer life of the oxide, lower pressure resistance and little maintenance. LESLIE B. BRAGG

Experience with continuous vertical retorts. W. H. DREAPER. *Gas Age-Record* 61, 907-9 (1928).—The Vancouver plant of the British Columbia Elec. Power & Gas Co., Ltd., using Glover-West vertical retorts is described. Its operation is discussed, with performance data on the waste-heat boilers being given. LESLIE B. BRAGG

British tests on the Crozier retort. A. C. BLACKALL. *Combustion* 18, 370-1 (1928).—A discussion. LESLIE B. BRAGG

The thermal insulation of retort settings. A. J. DALE AND A. T. GREEN. *Gas J.* 183, 37-42 (1928); *Gas World* 88, 712-8 (1928).—A review and general discussion. F. S. GRANGER

The Rochester silica gel light oil treating plant. R. E. KRUGER. *Gas Age-Record* 61, 577-8, 587-8 (1928).—A description of the plant at the Rochester Gas & Electric Corp., Rochester, N. Y. A ratio of not less than 200 parts of oil per part of gel is being used, producing an oil of 19 to 25 Saybolt color range. A cost of 0.75 cents more than the acid process per gal. of crude light oil is offset by a 13% greater yield. L. B. B.

The treatment of water-gas plant waste. E. J. MURPHY. *Gas Age-Record* 61, 817-8 (1928).—An installation at the Brooklyn Union Gas Co. plant is described. The raw effluent (waste water) from the separators of the water-gas plant is treated in a mixing tank with 5 lb. of lime and 4 lb. of FeSO_4 per 1000 gal. of effluent. The suspended matter coagulates almost immediately and is then sepd. in a Dorr clarifier. The cost is 24 cents per 1000 gal. LESLIE B. BRAGG

The evolution of the water-gas machine. F. W. STEERE. *Gas Age-Record* 62, 3, 5, 9, 10 (1928).—An historical review. LESLIE B. BRAGG

Rational presentation of flue gas analysis computations. R. H. MCCARTHY. *J. Eng. Education* 18, 940-4 (1928).—The computation procedure is based directly upon fundamentals, each step retaining a phys. conception. Examples are given. DAVID GORDON

Long-distance gas transmission. L. A. KIRCH. *Gas Age-Record* 61, 391-2, 402 (1928).—A consideration of the expenses and savings of centralized production and long-distance gas transmission. K. predicts that this centralization has only started. LESLIE B. BRAGG

Long-distance transmission of gas. ELVERS. *Z. Ver. deut. Ing.* 72, 869-75 (1928).—A discussion of two memoirs on the production and distribution of natural and manufactured gas throughout Germany, showing present and prospective sources, pipe lines and markets for gas. (8 maps) W. C. EBAUGH

Compression and transmission of carburetted water gas. M. P. CLEGHORN. Iowa State College. *Gas Age-Record* 61, 809-10, 819-20 (1928).—A consideration of the mech. losses caused by the compression and transmission of gas, with test data. LESLIE B. BRAGG

The corrosion of iron return mains. O. A. HILL, JR. *Gas Age-Record* 61, 429-30

(1928).—The collecting of CO_2 in "dead ends" of return lines may reduce the life of the line to $\frac{1}{8}$ of its normal life under uniform corrosion. **LESLIE B. BRAGG**

Pipe corrosion and protection. **W. G. HAGAN.** *Gas Age-Record* **61**, 697-8(1928).—A discussion. **LESLIE B. BRAGG**

Solving the dust problem. **R. C. BOUGHTON.** *Gas Age-Record* **61**, 625, 634(1928).—A description of an app. used to remove iron rust dust, resulting from the passage of dry natural gas through lines which had handled wet mixed gas. The app. consisted of a section of 20-in. pipe, 6 ft. long, which contained a 6-in. cylindrical muslin screen. The gas entered the 20-in. pipe and passed through the screen into a 6-in. main, the dust collecting on the outside of the screen and eventually dropping to the bottom of the trap. **LESLIE B. BRAGG**

Gas-measuring devices. **T. H. KERR.** *Gas Age-Record* **61**, 699-700(1928).—A discussion, with particular reference to the measurement of natural gas at the well. **LESLIE B. BRAGG.**

A. B. C. grate operation at the Minneapolis Gas Light Co. **H. B. YOUNG.** *Gas Age-Record* **61**, 813-4(1928).—The results of tests, with data, when operating in U. G. I. carburetted water-gas machines. **LESLIE B. BRAGG**

Fundamental principles in the design of gas-burning equipment. **N. T. BRANCHE.** *Chem. Met. Eng.* **35**, 357-60(1928).—The combustion mixt. must be supplied under sufficient pressure at the burner nozzles to have a higher velocity than the rate of flame propagation, as otherwise a flash-back occurs which ignites all of the mixt. in the manifold. A detailed description of proportioners for gas and air to secure max. efficiency is given. **J. H. PERRY**

The role of catalysts in high-pressure synthesis from water gas. **PERK F. FROELICH.** *J. Soc. Chem. Ind.* **47**, 173-9T(1928).—The high-pressure synthesis of NH_3 and of "Synthol" is briefly discussed. The latter process is considered to be prohibitive from a commercial standpoint because of the complexity of the products obtained. These two applications of high-pressure technic have demonstrated the possibility of synthesizing the entire aliphatic range of compds. from the cheapest grade of coal, and have stressed the necessity of bringing the reactions under control so as to obtain (1) one compd., (2) a limited no. of single compds. or (3) a mixt. of related compds. The synthesis of any aliphatic compd. is possible by studying intensively temp., pressure and specific catalysts. The synthesis of alcs. by oxide catalysts is outlined, and it is shown that there is a very close relation between the decompn. and synthesis of CH_3OH . **J. H. PERRY**

The conditioning of ammonium sulfate in large plants. **ANON.** *J. Indust. Gas* **52**, 271-3(1928).—The article deals mainly with the Wilton process, the special feature of which is the replacement of the centrifuges by a slow-moving acidproof metal-cloth belt conveyor on which the draining of the acid salt is completed and a preliminary drying is accomplished after neutralization. The belt acts as a filter, passing over 2 suction boxes, just after the salt is sprinkled by a dil. NH_3 soln. The belt delivers the nearly dry crystals, intact and uncaked, to a finishing drier, consisting of a bundle of steam-heated tubes, and passes through a washing trough on the way back. The final product contains not more than 0.1% moisture. **F. S. GRANGER**

Looking into the future of by-product ammonia. **C. J. RAMSBURG.** *Koppers Co. Chem. Met. Eng.* **35**, 417-8(1928).—Production statistics are given. It is predicted that production of by-product NH_3 will slowly increase. **E. H.**

Drying sulfur recovered from manufactured gas. **K. N. CUNDALL.** *Chem. Met. Eng.* **35**, 407-11(1928).—S sludge, 55% H_2O , recovered from gas plants (cf. *C. A.* **21**, 1699) was reduced in H_2O content by steam digestion, rotary drying or tunnel drying. The product is particularly applicable for insecticide or for soil treatment. Particle size is below that of any com. brand of S. **G. B. TAYLOR**

Gas from lignite. **DAVID BROWNLIE.** *Gas Age-Record* **61**, 355-7, 358(1928).—Lignite briquets yield a high-grade fuel on low-temp. carbonization but it has been found almost impossible to carbonize raw lignite of 35-40% moisture in this manner. High-temp. carbonization of briquets yields 8000-11,300 cu. ft. of 375-400 B. t. u. gas but the results have not been very conclusive as yet. **LESLIE B. BRAGG**

Gasification of lignite. **J. H. HRUSKA.** *Fuels and Furnaces* **6**, 907-8(1928).—H. discusses the use of lignite in the gas producer, important in Central Europe because of the large lignite resources in the vicinity of their steel mills and a corresponding lack of better fuel. Western Czechoslovakian lignite of 10,000 B. t. u. was gasified in a Kerpely producer at a rate of 51,170 lb. per day. A 136 B. t. u. gas of the following compn. was obtained: CO_2 3.8, CO 28.3, O_2 0.4, H_2 11.3 and CH_4 0.7%. 0.4-0.7 lb. steam per lb. lignite is required. A table shows the relationship between the compn.

of 8 lignites and the gases produced from them in various plants—fuel values of lignites varied from 8400 to 10,400 B. t. u.; resulting gases were within the following limits: CO_2 3.8–5.7, CO 25.4–28.9, H_2 9.7–12.4 and CH_4 0.8–1.4. ALDEN H. EMERY

The chemical analysis of benzenes. G. BANDTE. *Erdöl u. Teer* 4, 107–9, 131–2 (1928).—Analyses were made on straight-run petroleum, low-temp. coal tar and cracked gasolines and synthetic mixts. of these with benzene, by the Riesenfeld and Bandte (*C. A.* 20, 3346, 3801; 21, 489, 645, 1538) and Kattwinkel (*C. A.* 22, 3039) methods, comparing changes in oil and acid vols., different standing times, etc. In general, the decrease in oil vol. was found more accurate than the increase in acid vol. Violent shaking was unnecessary; 3 hr. standing was sufficient in all cases and 1 hr. in most. The Kattwinkel $\text{P}_2\text{O}_5\text{--H}_2\text{SO}_4$ soln. gave accurate results for unsatd. and aromatic, but, with high aromatic content, only if the sample was dild. with "normal" gasoline, whereas with the R. and B. method dildn. was unnecessary. The Kattwinkel boric-sulfuric acid soln. gave, with high unsatd. content, low values attributed to polymerization, and, with high aromatic content, high values, for unsatd., because of action on the aromatics. F. S. GRANGER

Low-temperature tar. JOHN M. WEISS. *Combustion* 18, 182–3(1928).—A discussion. LESLIE B. BRAGG

Low-temperature carbonization. H. D. SAVAGE. *Combustion* 18, 297–301 (1928).—Polymetal versus Weiss (cf. preceding abstr.). LESLIE B. BRAGG

The cracking of low-temperature coal tars. A. E. DUNSTAN AND H. G. SHATWELL. *Ind. Chemist* 4, 109–14(1928).—Two types of tar were investigated: (1) from feebly coking South Yorkshire coal, and (2) from a blend of a steam coal and a strongly coking coal. Straight-run spirits were obtained from these tars by steam distn., followed by fractionation of the distillate; the spirits so obtained showed anti-knock properties equal to C_6H_6 . An attempt to crack the distn. residue from the fractionation of the steam distillate yielded little cracked spirit and large amts. of pitch. Cracking stock was then prepd. by steam distg. 2 and topping the distillate to 170° . A portion of this stock was cracked as is, and another portion was sepd. by NaOH treatment into hydrocarbons and phenols, which were separately cracked. The phenols yielded simpler tar acids, but no hydrocarbons; the unsepd. stock yielded results intermediate between the phenols and the hydrocarbons. Pressure distn. of tar distillates from either type tar yielded 6.2 to 7.7% hydrocarbons, as compared to 36.8% from Persian fuel oil. T. S. CARSWELL

Tar emulsions. E. D. CARSWELL. *Gas Age-Record* 61, 661, 668(1928).—As a result of trouble experienced with tar emulsions which would not sep. in the separator a dehydrator was built to dry the tar. This consisted of a tank in which the tar was agitated with compressed air and heated with steam coils until all of the water was driven off, which was indicated by a rapid rise in the temp. of the tar. L. B. B.

The Rütgers viscometer. HEINRICH MALLISON. *Teer u. Bitumen* 26, 317–8 (1928).—The Hutchinson viscometer is recommended for roads tar but is not adapted to thinner tars because of the shortness of the measured time interval. The Rütgers viscometer is applicable to tars of all viscosities. F. S. GRANGER

Coke preparation. L. E. KNOWLTON. *Gas Age-Record* 61, 811–2, 814(1928).—A discussion. LESLIE B. BRAGG

The future of coke as domestic fuel. HAROLD J. ROSE. *Gas Age-Record* 61, 631–3(1928).—An address. LESLIE B. BRAGG

The new coke plant of the Lothringen concern in Hiltrop. HEINRICH KAMM. *Stahl u. Eisen* 48, 753–61(1928).—The daily output of the new plant is 1000 tons. The coal is first dried in a waste gas heater, then in a revolving furnace. The coke as a rule is cooled dry, its heat being utilized by a current of air for the production of steam. For an exigency a wet quenching equipment is provided, with notable labor-saving devices, for the transportation of the coke. The gases are washed with water which is not cooled, thereby effecting a sepn. of the volatile and non-volatile NH_3 compds. The S is obtained from the crude C_6H_6 by washing with NaOH . The economic advantages and the effected savings are discussed; plans and photographs of the new plant are given. J. A. SZILARD

Some factors influencing reactivity of coke. I. Carbonizing temperature and heat treatment in nitrogen. Institution Gas Fellowship Report. J. A. SUTCLIFFE AND J. W. CONN. *Gas World* 88, 709–12(1928).—To det. the influence of carbonization temp. on reactivity, cokes prepared at 500–1100°, with and without addn. of inorg. substances, were tested for reactivity in steam. Coke carbonized at 800° had the max. reactivity in all cases. 500° gave distinctly lower results and 1000° lower still. Fe_2O_3 , CaCO_3 , Na_2CO_3 and K_2CO_3 all showed a marked catalytic effect. The reactivity of coke prepd.

at 500° was very little affected by heating 2.5 hr. at 1000° in N₂, but heating 800° coke for 50 hr. at 900° caused considerable diminution in reactivity. **II. The effect of heating a coke in various gases on its reactivity.** F. J. DENT. The activity in CO₂ was detd. after treatment of the coke with H₂, CO, CH₄ or C₂H₄ for 1 hr. at various temps. After treatment with H₂ or CO the cokes had somewhat lower reactivity than the untreated, but after gasification in CO₂ for 2 hr. the difference in reactivity had disappeared. CH₄ lowered the reactivity decidedly. The diminution was lessened somewhat after passage of CO₂ for 2 hr. C₂H₄ had a more marked effect than CH₄, its greater decompn. affecting the coke by deposition of C on it. F. S. GRANGER

Reflux system and apparatus for fractional condensation of vapors from coal tar (U. S. pat. 1,676,232) 13. Conduit and associated apparatus for measuring the quantity of powdered coal carried in suspension (U. S. pat. 1,677,691) 1. Absorption plant [for treating coke-oven gases] (U. S. pat. 1,677,409) 1.

FABER, ALFRED **Braunkohlengeneratorgas. Band 16. Kohle, Koks, Teer.** Halle (Saale): W. Knapp. 263 pp. M. 16; bound, M. 17.80.

Fuel blocks. F. L. SHARP. Brit. 280,696, Oct. 29, 1926. Layers of pitch, resin or other highly combustible material may be placed between pieces of flat wood and the layers secured together. Various structural features are described.

Motor fuel. DAVID COSTAGUTA. U. S. 1,677,273, July 17. A mixt. for addn. to gasoline in order to prevent C deposition in engines comprises trinitrophenol 2, Et₂O 3, naphtha 20, "petroleum ether" 60 and ligroin 15%. Cf. C. A. 21, 2551.

Destructive hydrogenation of coal, oil, etc. INTERNATIONALE BERGIN-COMPAGNIE VOOR OLIE- EN KOLENCHEMIE AND A DEBO. Brit. 280,734, Jan. 10, 1927. A high-pressure reaction vessel is connected through a multiple condensing system to an engine which utilizes the pressure of the uncondensed gases.

Distillation of coal. MILON J. TRIMBLE. U. S. 1,676,675, July 10. Coal in a closed retort is treated with superheated steam under a pressure of not less than 5 lb. The steam and volatile products are led off, and fractional condensates and gas are recovered. An app. is described. Cf. C. A. 22, 1672.

Distillation of coal and other carbonaceous materials. FELIX FRANK (to Wm. W. Kemp). U. S. 1,677,757, July 17. Lignite or other carbonaceous material to be distd. is treated in an air-tight retort, which may be of the revolving type, by the direct action of a flame produced by burning a previously formed mixt. of gases including O, in the presence of inorg. catalysts such as Fe, Cu, Ni, W, V or their oxides, peroxides or salts. A similar procedure may be applied to coal, lignite, shale, peat, wood, heavy hydrocarbon oils, tars, asphalt, etc. App. is described. U. S. 1,677,758 specifies similar distns. under reducing conditions, *e. g.*, in the presence of an excess of H.

Combustible gas. WM W. KEMP. U. S. 1,677,785, July 17. Material such as coal is charged into a gas generator from which air is excluded and heated to form gas by projecting into the generator the flame produced by the combustion of a thoroughly premixed gas and air mixt., the quantity of O in which is not more than just sufficient for combustion of the mixt. itself (but not of the gas-forming material supplied to the retort). A vertical generator construction is described.

Apparatus for dewatering peat, etc. STEN V. C. PLATE. U. S. 1,676,459, July 10. **Gas producer (fuel agitator construction).** CHARLES W. LUMMIS (to Morgan Construction Co.). U. S. 1,676,148, July 3.

Electric safety control for gas burners. GERHARDT F. SCHWARTZ. U. S. 1,676,671, July 10.

Safety device for gas burners. A. HOFMANN and E. CONRAD. Brit. 280,768, March 7, 1927.

Lessening exhaust of carbon monoxide from internal-combustion engines. EDWARD J. LACY. U. S. 1,675,611, July 3. A perforated pipe leading to the engine intake is placed in the exhaust pipe.

Apparatus for cooling incandescent coke employing inert gas in a heat exchange system. ARNOLD MORTTELI (to Dry Quenching Equipment Corp.). U. S. 1,677,196, July 17.

Apparatus for cooling coke and heating a boiler plant by circulating inert gases. FRANKFURTER GAS GES, F. P. TILMETZ and F. SCHUMACHER. Brit. 280,514, Nov. 11, 1926.

Coke-oven construction. JOSEPH BECKER (to The Koppers Co.). U. S. 1,675,687, July 3.

Coke-oven construction. THOMAS G. KUS (to Chicago Trust Co., Trustee). U. S. 1,676,736, July 10.

Synthetic coke briquets for metallurgical uses. BERTRAM E. CROCKER. U. S. 1,676,729, July 10. The C residue obtained in the manuf. of oil gas is incorporated with a gas-liberating substance such as CaCO_3 , the mixt. is formed into briquets and the latter are heated to effect liberation of gas.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

F. M. ROGERS

Determination of the composition of petroleum. B. TARASSOV. *Neftyanoe Khozaystvo* 11, 67-70(1926); *Chem. Zentr.* 1927, I, 830-1; cf. C. A. 21, 1179.—An application of the method of Egloff and Morrell (C. A. 20, 1509). Unsaturated hydrocarbons can be detd. by extn. with H_2SO_4 only when they are present in high proportions; otherwise the method is not sensitive. The content of unsaturated hydrocarbons can, however, be detd. in an approx. manner by detg. the crit. temp. of soln. with PhNH_2 (T_c) before and after treatment with 80% H_2SO_4 . When the H_2SO_4 is washed out of the treated petroleum with aq. alkali, naphthenic acids are also removed and T_c is increased. Detns. of synthetic mixts. of saturated benzene and naphthenic acid gave the following values of T_c , the data showing the vol.-% of naphthenic acids and T_c , resp.: 0, 72.2°; 1, 71.0°; 5, 66.2°; 15, 54.0°; 30, 36.6°; 50, 5.0°. The detn. of aromatic hydrocarbons by nitration yields satisfactory results, though no general coeff. is applicable for converting the nitro derivs. to hydrocarbons. For each fraction investigated a suitable formula is given, from which the conversion coeff. is obtained. The principle that all paraffins have the same T_c value, which is diminished to the same extent by naphthenes, is erroneous in both respects.

C. C. DAVIS

The molecular weight of petroleum products. B. KAMINER. *Neftyanoe Khozaystvo* 11, 219-23(1926); *Chem. Zentr.* 1927, I, 828.—The mol. wts. of various petroleum fractions were detd. cryoscopically in $\text{C}_2\text{H}_4\text{Br}_2$, C_6H_{12} , stearic acid and C_6H_6 and ebullioscopically in C_6H_6 . In stearic acid soln., the mol. wt. is independent of the concn., whereas in C_6H_6 and in C_6H_{12} it increases with increasing concn. For products isolated in the lab., the following mol. wts. were obtained in C_6H_6 : crude petroleum 250-63, gasoline (b. p. up to 190°) 119-22, kerosene (190-259°) 166-70, "gas oil" (259-64°) 227-31, solar oil (264-310°) 288-97, machine oil (310-320°) 411-20, cylinder oil (322-330°) 474-81, tar 711-32.

C. C. DAVIS

The oxidation of hydrocarbons as a technical problem. FELIX HEBLER. *Erdol u. Teer* 4, 333-4(1928)—A literature survey on the oxidation of petroleum and similar products.

F. S. GRANGER

The unsaturated hydrocarbons in the different products of petroleum. G. GANE AND (MMR.) M. ZILISTEANU-GHEORGHIU. *Bul. soc. chim. Române* 8, 3-10(1926).—The authors tabulate the density, flash pt., viscosity, gelling pt. and iodine no. (Wijs method) of samples of distd. and refined oils obtained from Roumanian refiners. Their results indicate that the iodine nos. are higher for the crude distd. oils and lower for the refined oils. The results confirm the view that the iodine no. increases with the density and b. p. of the product. Synthetic mixts. of C_6H_{12} , C_8H_{16} , mesitylene and benzene were analyzed by Tansz method with $\text{Hg}(\text{OAc})_2$ to give close agreement with the theoretical for unsatn. The method of Botcher and Kramer, using oleum, gave quant. results for the aromatic hydrocarbons present. A sample of light petroleum with a d. 0.730 gave an unsatn. of 12.5% by the Tansz method. Other fractions have not yet given satisfactory results.

D. H. POWERS

Manufacturing oil from oil shale and bituminous coal. G. W. WALLACE. *Combustion* 19, 23-8(1928).—The Dundas-Howes process is described and discussed with estd. plant and operating costs.

LESLIE B. BRAGG

Oxidation of mineral oils in presence of soluble catalyzers. G. S. PETROV, A. I. DANILOVICH AND A. YU. RABINOVICH. *Papers Karlov Chem. Inst. Bach. Memorial Vol.* 1927, 157-68; cf. C. A. 22, 2073.—To det. which catalyzers have the most potent effect in the oxidation of mineral oils, Cu, Zn, Pb and Mn salts of naphthenic acids were tried under identical conditions. The max. of activity was found to belong to Mn salts, $\text{Mn}(\text{C}_7\text{H}_{15}\text{O}_2)_2$, the min. to Zn salts. The oxidizing influence of Mn naphthen-

ates has been compared with that of Mn salts of sulfo acids of high mol. wt. and the former were found to be more energetic. The oxidizing effect of Zn naphthenates has been compared with that of Zn stearate and it was found that the former is greater, but only on account of the formation of more oxyacids. Oils refined with H_2SO_4 oxidize about to the same extent as non-refined oils, but in the case of the former the yield in sol. acids is greater, whereas in the latter case more oxyacids are obtained. Distd. oils very highly refined with fuming H_2SO_4 do not oxidize in absence of catalysts even when treated with air at 150° for 40 hrs., but they darken as a result of decompn. The oxidation deepens the color of a mineral oil. BERNARD NELSON

The composition of the volatile fractions of Kashperovsk shale oil. G. L. STADNIKOV AND A. E. WEIZMANN. *J. Russ. Phys.-Chem. Soc.* **59**, 859-66 (1927). - The shale contained 13.4% H_2O , 46.25% ash and 3.8% S. By distn. from a Fischer retort, 15% oil was obtained. The fraction volatile with steam was treated with 3% $HCHO$, and 3% naphtha sulfo acids to remove S. compds of acidic character. Redistd. with steam, the oil was washed with H_2SO_4 and Na_2CO_3 solns and fractionated. The various fractions were acetylated in the presence of $SnCl_4$ ($AlCl_3$ gives rise to side reactions). Analysis showed the presence of C_4H_8S derivs.; they were further purified by crystn. of the semicarbazones. Semicarbazones m. $192-3^\circ$ and $199-200^\circ$, having the compn. formula $C_7H_7ON_2S$, were those of AcC_4H_7SEt or $AcC_4H_7SMc_2$. Two semicarbazones, m. 177° and 166° , resulted from the isomers of AcC_4H_7SPr . These conclusions were checked by the prepn. and analysis of corresponding p - $O_2NC_6H_4NHNH_2$ derivs. BASIL C. SOYENKOFF

Standards for kerosene. A. SAKHANOV. *Neftyanoe Khozyaistvo* **11**, 233-7 (1926); *Chem. Zentr.* **1927**, I, 672. - Surface tension and d. measurements vary but little and are of no significance. Viscosity depends chiefly upon the compn. of the petroleum and is governed by the latter. The appearance of a turbidity on chilling depends upon the presence of dissolved paraffin and is avoided by the proper regulation of the compn. In general the compn. is the determinative factor. The kerosene distillate ($200-270^\circ$) of Grosnyi petroleum burns in a satisfactory manner in ordinary burners, and higher fractions may be added only if ligrom fractions are also added. Petroleum from natural oils rich in asphalt must contain more light fractions. It is sufficient to establish lower permissible limits to the flash point, for even petroleum with a flash point of 60° yields good illuminating oil. The color is of little practical significance, and the presence of traces of resins (0.002% of heavy resin of d. 1.06 or 0.027% of light resin of d. 1.03), which intensify the color several degrees, do not affect the flash point. The content of unsatd. and of aromatic hydrocarbons is small in Russian petroleum and can be disregarded in formulating standards. The S content of Russian petroleum is very low. Contamination with naphthenic acids can be detected by simple tests. Admxt. of H_2SO_4 seldom reaches the harmful point. C. C. D.

Preparation of contact substances from the solar oils of Grosnyi. M. D. TILICH'EV AND A. I. DUMSKII. *Neftyanoe Khozyaistvo* **11**, 748-43 (1926); *Chem. Zentr.* **1927**, I, 2380. - The acids formed by the action of fuming H_2SO_4 on solar and machine oil distillates are used industrially as catalysts in the sapon. of fats, in the condensation of phenols with $HCHO$, etc. (cf. Petrov, *Neftyanoe Khozyaistvo* **1922**, 279, cf. *C. A.* **20**, 2394). The previously dried distillate is shaken at $50-60^\circ$ with 5% oleum (contg. 27% SO_3), the next day the acid layer (with the resins) is run off, the residual oil is aerated and is extd. with 3% (by wt.) of 48% $EtOH$. The aq. alc. ext. which contained S acids and the oil obtained from the extn. were studied, with special attention to the effect of repeated extn. Petroleum distillates of d. 0.883-0.898, n_D^{20} 1.49-1.50, viscosity 1.47-1.95 (Engler at 50°), were used in the expts. The acid no. of the aq. alc. ext., which serves as a measure of the S acid content, since approx. the same quantity of H_2SO_4 is always present, first increases and then diminishes. At the beginning a decrease in the acid no. corresponds to a decrease in the resinous substances in the acid layer, the oleum first causing resinification and then sulfonation. When the substances capable of being sulfonated are consumed, the oleum no longer reacts (aside from insignificant reactions which are manifest by the evolution of SO_2). The properties of the residue are not altered by further treatment. This residue has a lower d., viscosity, n value and $[\alpha]$ value and a higher "aniline point" (crit. temp. of soln. of the system with aniline) than the original oil. It consists chiefly of naphthene hydrocarbons, for the aromatic hydrocarbons undergo sulfonation. That sulfonation changes chiefly the aromatic hydrocarbons is shown among other ways by the fact that the higher the d. of the original oil, the greater the yield of "contact substance" (13-22% of the original oil). With this yield, 38-45% oleum is consumed. C. C. DAVIS

Sulfate-reducing bacteria in California oil waters. RUDOLPH GAHL AND BELLE

ANDERSON. Univ. of California. *Centr. Bakt. Parasitenk., II Abt. 73*, 331-8(1928).—Out of 40 wells sampled, 17 gave cultures of sulfate-reducing bacteria. In no case were pos. cultures found in surface waters. The cultures were all salt tolerant. All the cultures were variations of the original *Sp. desulfuricans* of Beijerinck. These organisms may have a bearing on the presence of *S in oil*, making it inferior for practical purposes.

JOHN T. MYERS

Some useful matters contained in forest trees in Japan. I. MIURA. *J. Coll. Agr., Imp. Univ. Tokyo* 9, 85-100(1927); *Expt. Sta. Record* 58, 202-3.—The fatty oils of the seeds of various forest trees found in Japan, the percentages of crude fat extd. from the powd. seeds of 44 species by treatment with ether of mixts. of the powd. material with anhyd. CuSO_4 , sand and Na_2SO_4 are reported in the form of giving the genus and species, the Japanese name, and the English name, if any, for the same genus, as well as the percentages of crude fat in the whole dried, ground seed and in the endosperm. There is also given the yield secured by pressing at ordinary temps. from the seeds of the 8 species showing the highest total crude fat in the first series of expts., together with the sp. gr., acid value, sapon. value, Wijs I no. and ester value, n , and Reichert-Meißl value, acetyl value, and percentage of unsaponifiable matter. A study is made of the oil product of 4 species of tung oil trees (*Aleurites cordata*, the aburagiri or Japanese tung oil tree; *A. fordii*, the Shina-aburagiri or Chinese tung oil tree; *A. montana*, the Kwangtung-aburagiri or Kwangtung tung oil tree; and *A. moluccana*, the Kukuinoki or tropical tung oil tree) grown in Japan. In addn. to the data given for the oils, for the 4 types of tung oil, the percentage found in the whole seeds and in the endosperm and the time required for drying at 95° are given for the 4 types of oil. The tannins of a large no. of species are studied, with results on the total tannin as detd. by an exhaustive method and by colorimetric estn. in 101 samples of various parts of 78 species and varieties, together with the type of tannin found in each case, and also the tannin content as detd. by the hide-powder method, and by oxidation of nontannin ext., and the reducing sugar in the ext. of 11 materials from 10 species and varieties selected from those of table 4 as worthy of this special study. The methoxyl content of the wood of the principal forest trees of Japan, the crude fractions obtained in the dry distn. of some of these woods, the percentages of MeOH and of acetic acid recovered, and the results of adding catalysts in the dry distn. of the sawdust of a fir (*Abies sachalinensis*) are tabulated. $(\text{NH}_4)_2\text{CO}_3$, the most efficient catalyst, increased the MeOH to a little more than one and two-thirds times the yield obtained in a blank distn. of the wood alone. The cultivation of cinchona in Formosa is discussed and the percentages of total alkaloids found in the roots, trunks, branches and leaves of *C. ledgeriana*, *C. hybrida* and *C. succirubra* grown at 3000 ft. and at 2800 ft. above sea level are given. The yields, sp. gr. and rotatory power of the needle oils of 26 Japanese conifers are given including a considerable no. of analytical data with respect to the oils of the twigs and leaves of *A. sachalinensis*, *Picea ajanensis*, *P. glehnii* and *Podocarpus macrophylla*. H. G.

GOTTWEIN, K.: *Kuhlen und Schmierer bei der Metallbearbeitung*. 2nd ed. Berlin: V. D. I. Verlag. 93 pp. Paper, R. M. G. Reviewed in *Mech. Eng.* 50, 577 (1928).

Cracking petroleum. LEE J. GARY (to Universal Oil Products Co.). U. S. 1,676,895, July 10. An app. is specified comprising heating coils, expansion chambers and dephlegmators between which and the expansion chambers pressure-reducing valves are placed which are connected with headers for equalizing the pressure on the different dephlegmators.

Cracking petroleum oils. FRANK A. HOWARD (to Standard Oil Development Co.). U. S. 1,676,894, July 10. A stream of oil heated to a cracking temp. is delivered into a "primary drum" in which the material remains at an elevated temp., above a cracking temp., but below the temp. of delivery into the drum; admixed conversion products are continuously removed from the drum and passed through a "secondary drum" of similar form maintained at a somewhat lower temp. and a portion of the material is recirculated from the secondary to the primary drum. An app. is described.

Cracking petroleum oils. GEORGE L. PRICHARD (to Gulf Refining Co.). U. S. 1,676,207, July 3. A body of the material is maintained in a still under cracking temp.

and pressure while withdrawing and condensing cracked products; the oil is agitated by a stirring device in the still operated by a shaft passing outside the still and which passes through a packing enclosed in a housing through which oil under pressure is circulated.

Cracking hydrogen oils. J. C. CLANCY. U. S. 1,658,116, Feb. 7. Crude petroleum or other oil under treatment is led together with H into contact with a molten body contg. NaCN, through a retort filling of Ni packing units maintained at a cracking temp.; the molten material is supplied to packing units and remaining unvaporized materials are withdrawn from them through liquid-sealed passages, and gases and vapors from the retort are recovered. An app. is described.

Cracking hydrocarbon oils. EDWARD W. ISOM and JOHN E. BELL (to Sinclair Refining Co.). U. S. 1,676,203, July 3. Oil is circulated to and from a bulk supply tank through a heater maintained at a cracking temp. and through a circulating pump having a drive shaft in loosely fitting bearings, while maintaining the oil under superatm. pressure; fresh oil also is fed to the still and a substantial portion of this fresh oil is forced through the pump bearings into the hot circulating oil.

Apparatus for cracking hydrocarbon oils in tubular pressure stills. EDWARD W. ISOM and ARNOLD C. VOBACH (to Sinclair Refining Co.). U. S. 1,676,204, July 3.

Cracking hydrocarbon oils. EDWARD W. ISOM and CHARLES L. PARMELEE (to Sinclair Refining Co.). U. S. 1,675,558, July 3. The oil is passed through a heating zone of restricted cross section such as a pipe coil in which it is heated to a cracking temp. and at an intermediate point in this heating zone there is added (before the oil becomes satd. with tar) an oil such as kerosene which is capable of acting as a solvent for tar which is formed during the process. An app. is described.

Cracking hydrocarbon oils. CHARLES L. PARMELEE and EDWARD W. ISOM (to Sinclair Refining Co.). U. S. 1,675,575, July 3. Oil is forced in a single pass through a cracking coil in which it is heated to a cracking temp. under high pressure, a solvent oil is introduced into the oil at an intermediate stage in its passage through the coil and the solvent oil is preheated by heat interchange with the cracked oil or its distillates. An app. is described. Cf. C. A. 21, 819.

Cracking hydrocarbon oils. EUGENE C. HERPHEL and THOMAS D. TIEFT (to Sinclair Refining Co.). U. S. 1,677,772, July 17. Oil to be cracked is forced in a single pass through a heating zone such as tubes in a furnace and thence into a primary vaporizing zone which may be in the form of a drum still and is maintained under superatm. pressure in both of these zones; unvaporized oil is passed from the primary vaporizing zone to an externally unheated secondary vaporizing zone which is maintained under a lower pressure than the primary vaporizing zone and vapors from the secondary vaporizing zone are taken off and condensed, oil condensed from these vapors is forced again through the heating zone, first in advance of fresh oil and then in admixt. with fresh oil, without returning to the heating zone unvaporized components of oil which have once passed through it, heating gases in the heating zone are passed first in heat exchange with the oil condensed from vapors from the secondary vaporizing zone and then in heat exchange with the mixt. of this oil with fresh oil; vapors from the primary vaporizing zone including those of desired oils of lower b. p. are taken off. App. is described. Cf. C. A. 21, 2556. U. S. 1,677,773 specifies a process in which vapors sep'd. from the oil withdrawn from pressure distn. are passed into a tower into the vapor space of which fresh oil is introduced so that it comes into direct and intimate contact with the vapors and effects their condensation; vapors from a pressure still are passed into a reflux tower and admixed condensate and unvaporized fresh oil are introduced from the first-mentioned tower into direct contact with the vapors; reflux is returned together with admixed unvaporized oil from the reflux tower to the pressure distn. App. is described. U. S. 1,677,774 specifies a pressure cracking process in which unvaporized oil is withdrawn from the pressure distn. and subjected to pressure reduction to effect further vaporization; vapors from the pressure distn. are taken off and condensed to produce pressure distillate and vapors sep'd. from the unvaporized oil withdrawn from the pressure distn. are fractionated and this fractionation is controlled by supplying a fraction, the constituents of which correspond to components of the desired distillate, to take off as vapors from the fractionation, a fraction the constituents of which correspond to the components of the pressure distillate; this fraction is condensed. App. is described. U. S. 1,677,775 specifies a process and app. somewhat similar to that of U. S. 1,677,772 as does also U. S. 1,677,776.

Distilling and cracking hydrocarbon oils. ROBERT T. POLLOCK (to Universal Oil Products Co.). U. S. 1,676,924, July 10. Oil which has been previously heated to a distg. temp. is passed in a restricted stream through a vaporizing zone such as a spiral pipe coil located outside the furnace where the initial heating of the oil has been

effected and in which no further rise in temp. occurs and vapors are released at different intervals during the travel of the oil through the latter. An app. is described.

Distilling hydrocarbon oils. ARMAN E. BECKER (to Standard Oil Development Co.). U. S. 1,676,724, July 10. A considerable body of oil is distd. in contact with steel wool and at a temp. not much in excess of the temp. of vaporization of the oil. The steel wool serves to equalize the heating. An app. is described.

Distilling hydrocarbon oils. ROGER D. HUNNEMAN (to Standard Oil Co. of Ind.). U. S. 1,676,609, July 10. Oil is passed in a stream through a heating device of restricted cross-section such as a heated pipe coil and into an enlarged sepg. chamber from which vapors and unvaporized liquid are separately removed. The unvaporized liquid is passed in counter-current to a current of steam and at least a part of the steam and vapors carried with it is faced into the stream of oil flowing through the heated zone. An app. is described. U. S. 1,676,610 ROBERT E. WILSON (to Standard Oil Co. of Ind.) relates to a somewhat similar process in which steam and assocd. vapors are forced into the stream of heated oil at an intermediate point in the heating zone; a sufficient head of liquid is maintained in the discharge line from the vaporizing chamber to prevent return of steam and vapors. App. is described. U. S. 1,676,611 ROGER D. HUNNEMAN (to Standard Oil Co. of Ind.) also specifies a process in which steam is supplied to the sepg. chamber at substantially the same temp. as the oil and in thermal equil. with it; the unvaporized oil is subjected to the action of live steam to remove lighter fractions and the latter are commingled with the vapors from the sepg. chamber and the latter are refluxed. App. is described.

Distilling and converting hydrocarbon oils. FRANK A. HOWARD (to Standard Oil Development Co.). U. S. 1,676,826, July 10. Residues such as topped petroleum are heated to effect partial conversion into products of lower b. p., under sufficient pressure to maintain the unchanged residue in the liquid phase; mixed conversion products are led into a chamber at lower pressure and fresh oil contg. constituents of low b. p. is passed in heat exchange relation with the conversion products at lower pressure removed from the chamber and subsequently in heat exchange relation with conversion products at higher pressure before they enter the chamber (without intermixt. of the fresh oil and other products); vapors evolved from the fresh oil are withdrawn and the residue is subjected to the other treatment described. An app. is described.

Apparatus for distilling hydrocarbon oils. C. W. STRATFORD. Brit. 280,727, Dec. 13, 1926. Oil is discharged by nozzles within a drum still against the heated surface of the still to keep the surface clean and effect rapid evapn. of the oil.

Refining petroleum oils. FRANK C. AXTELL (to Axtell Research Laboratories, Inc.). U. S. 1,677,425, July 17. Oils such as Calif. or other distillates are treated with H_2SO_4 solns. of persulfuric acid and Caro's acid, to remove S and other impurities.

Refining petroleum oils. WRIGHT W. GARY (one-half to Charles O. Middleton). U. S. 1,677,440, July 17. Dry gaseous SO_3 is passed through heated oils to remove impurities. An app. is described.

Recovering lead from sludge formed in petroleum refining. LLOYD B. SMITH and GEORGE W. JAMISON (to Atlantic Refining Co.). U. S. 1,676,294, July 10. The sludge which results from treatment of petroleum with Pb compds. such as an alk. soln. of Na plumbite is treated with a substance such as $CaCl_2$ soln. to break the emulsion of oil and water, the water which seps. is removed, and the remainder is ignited, leaving a residue of relatively high Pb content which may be smelted. An app. is described.

Converting hydrocarbon oils into lighter products. HENRY C. KIRK. U. S. 1,676,230, July 3. Upwardly directed streams of oil are injected into the lower portion of a body of oil maintained at a temp. and pressure which will effect conversion, to produce an upwardly moving current of oil; and a downwardly directed oil stream is injected into the upper portion of the body of oil to produce a downward current. The currents thus set up serve substantially to prevent deposition of C. An app. is described.

Separating from hydrocarbon mixtures constituents which precipitate at low temperature. NILS O. BACKLUND (to Bergedorfer Eisenwerk A.-G.). U. S. 1,676,069, July 3. Lubricating oil stock or similar mixt. of hydrocarbons is treated with a liquid such as C_2HCl_3 which has a sp. gr. higher than that of the heaviest of the hydrocarbon constituents which may be pptd. by cooling and which has a selective solvent action upon the fluid hydrocarbons present which are not so pptd., and the materials are then subjected to centrifugal sepn.

Apparatus for removing sediment and water from crude petroleum. JOSEPH C. UMBARGER. U. S. 1,675,775, July 3.

Removing wax from petroleum oils. L. D. JONES (to Sharples Specialty Co.).

Brit. 280,559, Nov. 9, 1926. Wax which cannot be removed by ordinary diluting, chilling and centrifuging is removed by first adding amorphous wax in such proportion that the wax pptd. on cooling is sufficiently heavy and amorphous, and then effecting the chilling and sepn. Centrifugal sepn. may be facilitated by the presence of some substances such as are ordinarily removed by acid or clay treatment of the oil.

Filter for gasoline, etc. CARL E. PEARSON (to Motor Requirements Corp.). U. S. 1,675,378, July 3.

Screen for filtering gasoline, etc. HENRY FORD. U. S. 1,677,118, July 10.

Apparatus for clarifying gasoline after use for cleaning. ARLIE C. BECK and ALVIE S. MORNINGSTAR. U. S. 1,667,324, July 17. The gasoline is filtered and treated with alkali.

Cylinder-oil mixture. RAYMOND T. HOWES (to Pan-American Petroleum Co.). U. S. 1,677,389, July 17. In order to reduce the surface tension of cylinder oil made from Calif. crude petroleum stock, for use in hydrostatic sight-feed lubricators, about 2.5% of Turkey red oil is added.

Automatic safety control for oil burners. HOMER S. ROGERS and RICHARD RADATZ (to Combustion Fuel Oil Burner Co.). U. S. 1,677,295, July 17.

Reclaiming naphthenic distillation residues. STEWART P. COLEMAN and WAYNE S. HUGHES (to Standard Oil Development Co.). U. S. 1,676,687, July 10. The hot residue such as that produced by distg. lubricating oil stock is discharged onto the surface of flowing water and stratification into layers is permitted, water and dissolved naphthenate are withdrawn from the bottom layer, the residual material is subjected to further stratification, oil is withdrawn from the top, and the water contg. metal naphthenates is withdrawn from the bottom layer. An app. is described.

Acid resins obtained from refining mineral oil derivatives. CARL SAUTERMEISTER and FRIEDRICH WILHELM. U. S. 1,677,731, July 17. In order to produce neutral bitumens from materials such as acid tars, the material is heated and agitated to sep. some of its assocd. H_2SO_4 , the H_2SO_4 which seps. is removed and the tar is heated to conc. the H_2SO_4 remaining; the temp. is raised to 130° and S is introduced to form H_2S and reduce the H_2SO_4 .

Lubricating oil mixture. JOHN H. MACKLE. U. S. 1,677,244, July 17. A mixt. suitable for use at high or low temps. comprises mineral lubricating oil 60, corn oil 20 and castor oil 20%.

Strainer for lubricating oil, etc. O. PETERSEN. Brit. 280,802, May 5, 1927.

Hand-operated tube and piston device for testing lubricating oils. ADOLPH A. SCHAEFER (to Frontier Mfg. Co.). U. S. 1,677,690, July 17.

Lubricating oil and asphalt from petroleum. ARTHUR E. PEW, JR. (to Sun Oil Co.). U. S. 1,675,462, July 3. The heaviest and less heavy constituents of heavy residual mineral oil are sepd. by subjecting a flowing shallow stream of the oil to a low abs. pressure and to a temp. above the vaporizing points of the less heavy constituents at the prevailing pressure and simultaneously passing through the stream a relatively light hydrocarbon material such as gas oil vapor which is substantially lighter than the less heavy constituents of the residual oil to assist vaporization of the latter. An app. is described.

Asphalt-mixing plant. FREDERICK H. CUMMER. U. S. 1,677,274, July 17.

Treating asphaltic compositions with copper sulfate. FRANCIS L. CARSON. U. S. 1,677,272, July 17. An aq. soln. of $CuSO_4$ is first mixed with a small quantity of bitumen to form a mixt. much richer in $CuSO_4$ than that finally desired, the water is allowed to evap. and the remaining mixt. is then mixed with a further quantity of hot bitumen.

Carbonizing wood or other materials. WM. W. KEMP. U. S. 1,677,784, July 17. A mixt. is formed including combustible material such as gas and just sufficient of a supporter of combustion such as air to effect combustion of the combustible material, this mixt. is burned in a retort from which air is excluded and material such as wood, lignite or peat is passed through the retort and subjected to the direct action of the flame from the burning combustible mixt. An app. is described.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Investigation of "resin precipitations." ARNOLD TYDEN. *Svensk Pappers-Tid.* 31, 265-7(1928).—"Resin pptns." in this paper refers to those sticky, viscous, resinous deposits of varied character that appear at various stages in the manuf. of pulp and

paper, usually in the wet parts of the machinery. They originate in the "resin content" of the wood and are composed of the same main constituents, which are resinous acids and fatty acids, oleic acid predominantly, together with indifferent substances of an unknown nature. They are probably formed by the coagulation and pptn. of the resin constituents which are at first suspended in water as a finely dispersed emulsion. The purified "resin content" of several samples was sepd. into resinous acids, fatty acids and indifferent substances. The acid constituents were sepd. from the indifferent substances by means of their soly. in alkali. The resinous acids were sepd. from the fatty acids by esterification; the former were left intact and were dissolved by alkali out of the ether soln. of the mixt. Resin taken from the mixt. of a sulfite chest contained approx. equal amts. of resinous acids, fatty acids and indifferent substances. Analysis of raw-material sulfite resin gave: fiber and mineral compds. 12.0, resinous acids 19.5, fatty acids 27.0, indifferent substances 21.0, ppt. insol. in ether 1.0, balance (water, etc.) 19.5, sum 100.0%. Analysis of resinous acids gave: acid no. 156, sapon. no. 177, I no. 77.5, C 73.84% and H 10.00%. Analysis of fatty acids gave: acid no. 154, sapon. no. 168.5, I no. 69.5, C 74.90% and H 8.82%. The close agreement of these 2 analyses makes further study of these fractions highly desirable. The investigation is to be carried out along these lines and will be extended to other characteristic "resin pptns" from different places in the pulp and paper mills.

WILHELM SEGERBLOM

Contribution to the chemistry of digesting sulfite cellulose. XI. The decomposition of pine and fir wood with sulfurous acid. ERIK HAGGLUND AND TORSTEN JOHNSON. *Scensk Pappers Tid.* 31, 263-5(1928). (In German.)—Expts. in pulping wood by digesting with H_2SO_3 , but without sulfite, various boiling temps. being used, are reported. With a relatively high acidity of liquor and a relatively low temp. the solid ligno-sulfonic acid of the residue changes to a dark color. This is probably due to resinification or condensation and retards the recovery of the lignin. A good pulp can probably not be obtained from the use of H_2SO_3 alone as the resinification probably cannot be obviated. Cf. C. A. 22, 1679.

WILHELM SEGERBLOM

The chemistry of wood cellulose. IV. Isolation, analysis and chemical properties of cellulose from red spruce (*Picea rubens*). E. C. JAHN AND I. E. WISE. *Paper Industry* 10, 244-52(1928); cf. C. A. 16, 1664; 17, 3098.—The isolation of crude cellulose from red spruce (*Picea rubens*) was effected by 5 different methods. The most homogeneous prepn. was apparently that obtained by bleaching sulfite pulp. The purest and most homogeneous α -cellulose prepn. was that obtained from Cross and Bevan cellulose. The methods of isolating "crude" and "alpha" cellulose were studied and described in detail. The source of the wood used was known and the material was chemically analyzed for α -, β - and γ -cellulose, pentosans, residual lignin, and, in a no. of cases, C and H. The latter was of relatively little value in judging the homogeneity of cellulose prepn.s. D'Ans and Jager's statement that cellulose is most sol. at 23° in 12% NaOH was not substantiated. The removal of pentosans from cellulose by alkali treatment was shown to increase with increasing strength of alkali. Upon retreatment with alkali the pentosan content of the cellulose reached an irreducible min. It was impossible to obtain any α -cellulose prepn. in such a form that it remained completely insol. in NaOH on retreatment with alkali. This confirms the findings of Tauss (*J. Soc. Chem. Ind.* 9, 883(1890)). The best methods of drying α -cellulose prepn.s. were studied. Drying at 100-5° was ordinarily satisfactory. Air-dried material could be completely dehydrated at 78° in *vacuo* over P_2O_5 . At lower temps., however, the cellulose absorbs H_2O in such an evacuated system.

A. PAPINEAU-COUTURE

The chemistry and technology of cellulose. R. E. MONTONNA. *Paper Trade J.* 86, No. 18, 61-7(1928); *Tech. Assoc. Papers* XI, 84 90(June, 1928).—A brief review of the more important publications covering the whole field, with about 500 references selected on the basis of their importance and of their probable availability. A. P.-C.

Study of our knowledge of the chemistry of lignin. G. DUPONT. *Chimie et Industrie* 19, 3-23, 407-16(1928).—A review of the chemistry and technology of lignin.

The chemistry of lignin bodies. KARL KURSCHNER. *Paper Trade J.* 86, No. 16, 62 71(1928); *Tech. Assoc. Papers* XI, 100-9(June, 1928).—A critical review with bibliography.

A. PAPINEAU-COUTURE

Structure of mercerized cellulose. I. The space lattice of mercerized ramie cellulose as developed from x-ray data. O. I. SPONSLER AND W. H. DORR. Univ. of Calif. *J. Am. Chem. Soc.* 50, 1940-50(1928); cf. C. A. 21, 3268.—X-ray diffraction data are given for ramie cellulose which has been subjected to mercerization processes with various strengths of NaOH solns. The evidence shows that there is a critical concn. of the alkali at about 13%, above which the fibers are mercerized, below which

they remain unmercerized. From the diffraction patterns of mercerized ramie cellulose a space lattice has been developed. When compared with the unmercerized lattice the c axis is seen to be unchanged, while the a and b axes have been changed from $a = 5.40$ in the unmercerized to $a = 4.53$ in the mercerized and from $b = 6.10$ to $b = 7.61$ A. U. The angle between axes a and b has been changed from 90 to 83° . As a result of mercerization the chains of glucose units have been shifted laterally in the wall of the fiber and have remained unbroken. Within the chain the original glucose unit has remained unchanged except for a shift of the HO of the 6th C atom. The x-ray diffraction patterns indicate that there has been a partial rotation of some of the glucose units about the long axis of the chain. A comparative study of the structures of mercerized and unmercerized cellulose has produced additional support to the view that the constituent units of cellulose are united in chains by primary valence linkages. C. J. W.

Lignin and cellulose. VI. **Methylcellulose.** KARL FREUDENBERG. Univ. Heidelberg. *Ann.* **461**, 130-1 (1928).—Comments on the work of Sponser and Dore (C. A. **21**, 3268). C. J. WEST

Behavior of cellulose on heating under pressure with water. E. BERL AND A. SCHMIDT. Tech. Hochschule, Darmstadt. *Ann.* **461**, 192-220 (1928).—Results are given of heating 10 g. cellulose (cotton linters) with 110 g. distd. H_2O at temps. from 150° to 350° in a Bergius high-pressure bomb. Practically no change is noticed at 150° ; at 175° the product suffers little change, but may be powdered between the fingers. Gas production begins to be pronounced at 225° , consisting principally of CO_2 at that temp. As the temp. increases the quantity of CO_2 formed gradually decreases and that of CH_4 increases, until at 350° the gas has the compn. CO_2 , 77.8; CO , 7.3; H_2 , 2.6; CH_4 , 8.0; C_nH_m , 3.2. The quantity of CO varies only from 6.4 to 8.6% in going from 225° to 350° . The vol. of gas formed increases from 350 cc. at 225° to 1600 cc. at 350° . The reduction no. (mg. Cu) appears to reach a max. at 225° (1778) and then gradually decreases to 800 at 350° . The H_2O -sol. portion contains HCO_2H and a brown, amorphous product, with an acid reaction and reducing capacity (NH_4OH - $AgNO_3$, Fehling soln.), which resembles humalic acid. The original should be consulted for the details of the analyses C. J. WEST

The action of strong caustic solutions on cellulose. PERCY WAENTIG. *Papier-Fabr.* Fest- und Auslands-Heft, **26**, 64-6 (1928).—Alkali-cellulose aged in a closed flask 40-50 days takes up about 1.3% O, but the decompn. product is not "oxycellulose," since the Cu no. is but slightly increased. There is a large decrease in α -cellulose. When the pulp is both mercerized and aged in a vacuum, there is an actual increase of about 1% in the α -cellulose value, and the viscose prepd. from such pulp is much more viscous. These observations may be of importance in the rayon industry; they indicate a serious source of error in the present α -cellulose detn. R. H. DOUGHTY

Manufacture of high- α -cellulose. JOSEPH ROSSMAN. *Paper Trade J.* **86**, No. 15, 59-63 (1928); *Tech. Assoc. Papers* **XI**, 187-91 (June, 1928).—A review of U. S. and foreign patents. A. PAPINEAU-COUTURE

The determination of α -, β -, and γ -cellulose. GUNNAR PORRVIK. *Papier-Fabr.* **26**, 81-5, 120-4, 133-9, 151-7, 179-83 (1928).—The sources and magnitude of the errors in this detn. have been studied in detail. The methods used were the usual Jentgen method (I) and a titration method (II) carried out as follows: 2.5 g. pulp is treated 30 min. with exactly 70 cc. of mercerizing soln., which is then filtered off without diln. Of the filtrate, 50 cc. is used for the detn. of β - and γ -, the remainder being added to the α -pulp, which is then dissolved in concd. H_2SO_4 . Cellulose is detd. in the solns. by oxidation with $K_2Cr_2O_7$ (cf. Bray and Andrews, C. A. **17**, 1714). On the assumption that the 50 cc. of soln. used for the detn. of β - and γ -values contains exactly $\frac{1}{2}$ of the hemicelluloses, the true α -, β -, and γ -values are calcd. Repeated extn. of the α -portion with mercerizing soln. shows that this assumption is correct within 0.1%. In both I and II β - and γ -values are detd. by titration. The degree of neutralization and heating used in sepp. the β -cellulose has a marked influence on the β - γ -ratio. In I, the first 1000 cc. of filtrate contain 97% of the hemicelluloses. The α -values from I are decreased 1% by changing the temp. of treatment from 20° to 0° ; by doubling the kneading time; or by changing the relative humidity at which the pulp is dried (at room temp.) from 100 to 0%. They are decreased 1.5% by doubling the vol. of mercerizing soln., or by changing the concn. of the soln. from 18 to 24% by weight. With a mercerizing soln. contg. 30% EtOH (to inhibit swelling) the α values are 4-5% higher than in aq. NaOH, and nearly independent of the soln. vol. With method II, the α values were found to be roughly in inverse ratio to the degree of swelling in NaOH solns. of varying concn. The lowest values were found in solns. of 12 g. per 100 cc. Diln. of a more concd. soln. than 12% before filtration (as in method I) gives α -cellulose values corresponding to a 12% soln..

while diln. of a more dil. soln. has no effect. Finally, though 6% and 22% solns. give nearly the same α -cellulose values, by II, the stronger soln. gives a purer cellulose, as shown by Cu no. and viscosity detns. Many exptl. data are discussed in detail, with the following conclusions: The soln. of hemi-celluloses is governed by 2 interdependent sets of factors, one related to swelling and mech. condition of the pulp, the other to temp. and time of treatment. γ -Cellulose is an end product, β -cellulose an intermediate product in the degradation of cellulose by concd. NaOH. The most serious error in the Jentgen method is caused by the diln. before filtration. Details are given of two new methods for α -cellulose detn., which are stated to give improved accuracy and reproducibility of results. Both use 2.5 g. pulp, 70 cc. of soln., and a mercerizing time of 30 min. In the *minimal method* (III) the soln. contains 12 g. NaOH per 100 cc. The pulp after filtration is washed with four 25-cc. portions of this soln., then with H₂O and acid in the usual way, dried and weighed. In the *alcohol method* (IV) the NaOH soln. contains 21.8 g. per 100 cc. The pulp is treated as in III except that the washing with mercerizing soln. is followed by a wash with four 25-cc. portions of 95% EtOH. Method III gives approx. the "true content of resistant cellulose," while IV shows how much will withstand the alkali treatment in the prepn. of viscose. Typical results given by methods I, II (with 21.8% by vol. NaOH), III and IV, resp. are: for cotton pulp, 96.7, 99.2, 94.5, 98.8; good viscose pulp, 88.2, 89.9, 83.6, 89.2; poor pulp, hardly suitable for viscose, 87.3, 88.6, 82.5, 86.9.

R. H. DOUGHTY

Benzylcellulose and its uses. CLEMENT AND RIVIERE. *Z. angew. Chem.* **40**, 1579 (1927).—Benzylcellulose can easily be obtained by acting with benzyl chloride at definite temps. on alkali celluloses. This benzylcellulose is sol. in acetone and in a mixt. of alc. and benzine, and in many org. products of high-boiling pts., such as plasticizers. It is useful in the manuf. of protective coatings and lacquers. B. H.

X-ray spectrographic investigations on celluloid. KOGAKUSHI HAJIME UEDA Kaiser Wilhelm Inst. f. Faserstoffchemie, Berlin-Dahlem. *Z. physik. Chem.* **133**, 350-6 (1928).—Nitrocellulose fibers, themselves giving a sharp crystal-fiber diffraction pattern, absorb camphor until the pattern is "amorphous." Extn. of the camphor regenerates the nitrocellulose with its original pattern unchanged, unless very large amts. of camphor are involved. Technical celluloid produces a diffraction pattern consisting of 2 intense and several weak Debye-Scherrer rings. This is a superposition effect of the diagrams of both components, the positions and intensities being functions of concns. The inner strongest interference ring approaches the camphor interference with increasing concn. of camphor. At high concns. (70%) the diagram shows crystn. of the camphor. The same thing happens at lower concns. when the celluloid is strongly stretched. The x-ray results indicate the existence of a solid soln. and not of stoichiometric compd. formation. When a film of nitrocellulose is stretched a fiber pattern is obtained.

Studies of the chemistry of wood. II. The "Todomatsu" pine of Karafuto. YOSHISUKE UEDA AND GOICHI YAMADA. *J. Cellulose Inst. Tokyo* **2**, 25-6; *Chem. Zentr.* 1926, II, 3083.—The wood of this pine is used for the production of *sulfite cellulose*. The effect of the mannan present on the properties of the cellulose and on the utilization of the spent liquor through fermentation is discussed. C. C. DAVIS

The German requirements governing the determination of the moisture content in mechanical wood-pulp. ANON. *Svensk Pappers-Tid.* **31**, 355-6 (1928).—Specific directions are given for taking and handling samples of the main supply, for drying, weighing and calcn. of moisture content as established in Germany. W. S.

The chemical decomposition of wood. BROR HOLMBERG. *Svensk Pappers-Tid.* **31**, 256-8 (1928).—Investigations into the alcoholysis of wood by Holmberg and Rinius (cf. *C. A.* **20**, 774) were continued by treating the alc. with mercaptans such as benzylmercaptan or thioglycolic acid. The latter was especially suitable because of its power of making a soln. and because of the characteristics of the resulting lignin compds. These compds. consisted of esters which could be saponified into ligno-thioglycolic acid, the compn. of which was approx. $C_{40}H_{40}O_{13} \cdot 2HOCOCH_2SH$ and $C_{40}H_{40}O_{13}$.

4HOCOCH₂SH. From 10 g. of pine wood meal 2.7 g. of these acids were obtained.

WILHELM SEGERBLOM

Poplar as a raw material for paper making: micrographic study. L. VIDAL. *Paper* 31, 393-7(1928).—A discussion of the micrographic characteristics and pulping and paper making merits of poplar, particularly to meet conditions in France. Its advantages for groundwood manuf. are particularly stressed. A. PAPINEAU-COUTURE

Chemical wood pulp from poplar and from deciduous woods in general. M. BROU. *Paper* 31, 399-402(1928).—B. considers that poplar and similar species can give bleached sulfite, and particularly bleached soda, pulps which can be used to advantage, in admixt. with stronger pulps, in the manuf. of fine papers. Esparto and straw pulps, prep'd. either by the soda, Cl hydrate or neutral sulfite processes, are suitable as substitutes for chem. poplar pulp. In order to be economically successful poplar should be procurable at approx. $\frac{1}{3}$ the cost of spruce or fir (wt. for wt.). Proper alkali recovery is essential to the successful operation of the soda process. Poplar soda or sulfite pulp cannot be economically used for the manuf. of viscose rayon or for nitration purposes.

A. PAPINEAU-COUTURE

The pulping of hardwoods and mixtures of hardwoods and conifers by the sulfite process. W. H. MONSSON. *Paper Trade J.* 86, No. 17, 59-62(1928); *Pulp Paper Mag. Can.* 26, 705-9(1928); *Tech. Assocn. Papers* XI, 121-4(June, 1928).—A study of the sulfite pulping of hardwoods, both alone and in admixture with conifers, showed that: (1) Aspen, maple, birch and black gum are readily reduced by the sulfite process, giving high yields of bleachable pulp suitable for a no. of grades of paper and paper board. (2) Mixts. of the above hardwoods and spruce or hemlock are as readily pulped as the hardwoods themselves, giving good yields of bleachable pulp equal or superior in strength to pulps produced from the hardwoods alone. (3) A cooking acid of high free SO₂ and a long impregnation period are desirable to insure thorough penetration of the chips by acid and uniform cooking. (4) Cooking schedules previously found suitable for spruce are equally good with only slight modification for the hardwoods and mixts. (5) The advantage of good yields noted for hardwoods is enhanced by the greater wt. of such species per cord.

New suggestions for utilizing pulp waste-liquors. A. SCHROBE. *Papier-Fabr.* 26, 241-8(1928).—A review of patents issued during 1925-6-7. Cf. C. A. 19, 2564; 20, 988.

R. H. DOUGHTY

Some viewpoints on sulfite cooking. E. ÖMAN. *Svensk Pappers-Tid.* 31, 259-63(1928).—In the sulfite process the org. substances dissolved in the digesting liquor absorb increasing amts. of H_2SO_3 . Sulfite waste liquor when mixed with SO_2 -water absorbs large amts. of H_2SO_3 . This absorption is a time reaction; at ordinary temp. equil. is attained only after several days, while at 100° it takes only hrs. The reaction is reversible. When lime or some other base is present, more SO_2 is absorbed than when no base is present, the amt. of SO_2 increasing with the concn. of sulfite in the waste liquor. This accounts for the varying consumption of S in different sulfite mills. The temp. and pressure change with varying concn. of sulfite on account of the pressure of the liquid with consequent variation in the soly. of SO_2 and in equil. points. Circulation of the liquor produces a more even temp. and SO_2 concn.

W. S.

Regeneration of alkali from sulfate waste liquor, with simultaneous production of by-products. ADOLPH MATZNER. *Wochbl. Papierfabr.* 59, 119-21(1928).—A process is described by which the concd. liquor is treated with $NaHSO_4$ to ppt. the lignin, which is filter-pressed and subjected to destructive distn. The coke is heated in a reducing furnace to regenerate sulfide, and the Na_2SO_4 liquor from the filter is causticized with lime. No operating data are given.

R. H. DOUGHTY

Some experiments in processing pulp in the rod mill. G. H. CHIDESTER. *Tech. Assocn. Papers* XI, 127-40(June, 1928); *Paper Trade J.* 86, No. 25, 51-64(1928).—Investigation of the action of the rod mill showed that a less severe action is needed in developing strength qualities than in the disintegration of chips or fiber bundles and that the use of a higher consistency of stock and lighter rods is desirable. By proper selection and control of consistency and ratio of wt. to surface of the rods, a given strength property can be brought to a max. considerably higher than can otherwise be reached. The higher the consistency or the lighter the rods the less is the cutting effect as compared to the hydration. Power consumption required to develop a given degree of strength is lower in the rod mill than in the beater.

A. PAPINEAU-COUTURE

White water treatment. JAS. STRACHAN. *World's Paper Trade Rev.* 89, 704, 770, 772(1928); *Paper Maker & Brit. Paper Trade J.* 75, 339B(1928).—A discussion of the requirements of a proper white-water treating system, the 2 aims of which are recovery of stock and prevention of pollution by the paper mill effluent. S. shows that a closed white-water system is entirely feasible and practical and discusses its advantages.

A. PAPINEAU-COUTURE

The manufacture of bleached sulfite pulp on the Pacific Coast of British Columbia. W. L. KETCHEN. *Pulp Paper Mag. Can.* 26, 765-70(1928).—A detailed description of the sulfite process, from wood to finished products, with particular reference to conditions on the Western Coast of Canada.

A. PAPINEAU-COUTURE

Use of magnesia instead of lime in sulfite cooking. O. HILLER. *Papier* 31, 195-6(1928).—After reviewing previous work on the advantages of MgO -base sulfite liquors, H. gives the results of lab. expts. and of mill experience, from which he concludes that by replacing half of the CaO by MgO the cook can be carried out more rapidly and at a higher temp.

A. PAPINEAU-COUTURE

Consumption of coal and of chemicals in continuous alkaline cooking. RAYMOND FOURNIER. *Papeterie* 50, 358-65(1928).—After a discussion of the advantages of continuous alk. cooking of slightly lignified material at atm. pressure, with simultaneous mech. treatment to effect deligning, F. calcs. the cost of such treatment of straw, showing that semi-chem. straw pulp can be obtained at a cost of 39.70 francs (about \$1.60) per 100 kg. air-dry, by treatment with CaO and Na_2CO_3 .

The composition and utilization of "tallol." MAURICE DE KEGHEL. *Pulp Paper Mag. Can.* 26, 529-31, 546, 548(1928).—See C. A. 21, 1354.

A. P.-C.

Saturation of spruce wood (with sulfite liquor). C. G. SCHWALBE and WERNER

LANGE. *Papier-Fabr.* 26, 238-41(1928).—Heart-wood and sap-wood absorb practically the same amt. of NaHSO_3 soln. but the former absorbs considerably more $\text{Mg}(\text{HSO}_3)_2$ than the latter. Using cylinders of sap-wood 3 by 3 cm. in size, with solns. contg., resp., Na, Mg and Ca as base, and equal amts. (4.5%) of total SO_2 , the amt. absorbed varies in the order: bisulfite + free SO_2 > sulfite > bisulfite. The base used has little effect. Solns of SO_2 or NaOH are absorbed more than any soln. contg. both. Absorption is apparently complete in 32 hrs., at which time the inner part of the stick contains an excess of free SO_2 , and the outer part an excess of base, when Na salts are used. This sepn. of the base does not occur with Ca or Mg salts; the reason is obscure.

R. H. D.

New developments in (waste) liquor evaporation. J. HAUSEN. *Papier-Fabr.* 26, 173-9(1928).—Mechanical. Elec scale prevention, waste-steam conversion, and the burning of atomized sulfite waste liquor are considered.

Results with testers for measuring tensile strength of paper. R. E. LOFTON AND L. W. SNYDER. *Paper Trade J.* 86, No. 24, 63-6(1928).—Results are tabulated and plotted for tensile strength of seven different papers detd. with six types of tensile strength testers at present on the market, one of which was found to be unsatisfactory for some cause which was not ascertained. The reliability of the results obtained with the various instruments is discussed.

A. PAPINEAU-COUTURE

Paper testing at the Government Printing Office. E. O. RERD. *Paper Trade J.* 86, No. 15, 42-8(1928).—A report of the work carried out in 1927 by the Division of Tests and Technical Control of the U. S. Govt. Printing Office.

A. P.-C.

Increasing the capacity of the Elmendorf tearing tester. F. T. CARSON AND L. W. SNYDER. *Paper Trade J.* 86, No. 13, 57-60(1928).—In order to increase the capacity of the tester by merely increasing the wt. of the pendulum in such a manner as to make the present scale graduations usable without complicated conversion formulas or tables, and so that the tester might be quickly convertible from the heavy-duty to the present form, or vice versa, an adequate fundamental calibration formula was derived, the scale was calibrated according to this formula, and from the formula and the calibration data a wt. was designed which could be inserted in the opening in the sector of the pendulum so as to double the capacity of the tester without necessitating any other modification of the original design. A no. of modifications in the design of the instrument are suggested to improve its performance.

A. PAPINEAU-COUTURE

The McLaurin gummed tape tester. ANON. *Paper Trade J.* 86, No. 14, 61

(1928).—The test is carried out as follows: the tester is leveled and adjusted to zero setting, the pointer is moved to a position in contact with the carrier attached to the pendulum shaft, 2 sheets of good grade kraft paper, cut to standard length, are inserted and held fast by 2 clamps, a moistened strip of gummed tape is attached to the kraft paper, a short time is allowed for partial setting of the glue, and the pendulum release lever is then tripped. The pendulum exerts a const. pull on the test piece, and the resistance value of the moistened glue at the critical period is indicated on the scale. The actual time to make the test is only about 15 sec. The merits of the instrument are briefly discussed.

A. PAPINEAU-COUTURE

A study of the Thwing impact tester. II. C. ECKHARDT AND L. W. SNYDER. *Paper Trade J.* 86, No. 15, 64-6(1928); *Tech. Assn. Papers* XI, 91-3(June, 1928).—The construction and principles of operation of the instrument are presented, together with a method of calibrating it. A study of this tester showed that it is apparently well adapted for testing boxboards, a purpose for which it was primarily designed. It is unsuited, however, for testing single plies of light wt. paper, because the resistance of such paper is insufficient to give an adequate scale reading. Consistent results were obtained with this instrument, which compared favorably with the results obtained by the hydraulic type of bursting strength tester. Just what the results mean, however, in terms of serviceability of the board can be detd. only through extensive experience. A. P.-C.

The use of corrosion-resisting steels in the paper industry. JOHN A. MATHEWS. *Paper Mill* 51, No. 22, 24-8(1928); *Paper Trade J.* 86, No. 24, 60-2(1928).—An address outlining recent progress in the production of corrosion-resisting alloys suitable for paper mill use.

A. PAPINEAU-COUTURE

British Guiana woods for paper making. II. ANON. *Bull. Imp. Inst.* 26, 4-17 (1928).—A report on the analysis and pulping tests of 11 samples of commonly occurring timbers of British Guiana, which are likely to furnish considerable quantities of waste wood when the forests are eventually worked. The pulping tests were made with 20% NaOH (at 4% concn) on the wt. of the wood, and cooking at 160°, the time being varied with the different samples so as to obtain proper disintegration. In 6 hr. *Greenheart* (*Ocotea Rodiei*, Schomb.) gave 41.0% of well-digested pulp which furnished a pale brown paper. It did not bleach readily and required about twice as much bleaching soln. as is necessary for poplar pulp, giving a 38% yield of bleached pulp which furnished a soft, rather bulky, cream-colored paper of moderate strength. In 5 hr. *Wallaba* (*Eperua falcata*, Aubl.) gave 35% of well-reduced pulp which felted well and furnished a soft grayish brown paper of good strength and quality. The pulp bleached readily to a pale cream color, yielding 32% of bleached pulp. In 5 hrs. *Kakaralli* (*Eschweilera laevisfolia*, Miers?) gave a 45% yield of well-reduced pulp, which furnished a soft brown paper of moderate strength, but which could not be bleached beyond a pale yellowish brown. Increasing the time of cooking to 6 hrs. reduced the yield to 35%, but did not improve the bleachability. In 5 hr. *Mora* (*Dimorphandra mora*, Benth. and Hook?) gave 48% of well-reduced pulp which furnished a strong pale brown paper, but which could not be readily bleached; increasing the cooking time to 6 hrs. reduced the yield to 41% of pulp which, after bleaching, yielded a strong white paper of good quality. In 6 hr. *Yaruru* (*Aspidosperma excelsum*, Benth?) gave 46% of well-reduced pulp which furnished a weak, soft, rather dark brown paper, and which could be bleached only to a yellowish brown. In 5 hr. *Itikibourballi* (*Leguminosae*, genus indeterminate) gave 42% of well-digested pulp, which furnished a soft, rather bulky pale brown paper of moderate strength, and which did not bleach readily, requiring a strong bleaching soln. to reduce it to a cream color. In 5 hr. *Trysil* (*Pentaclethra filamentosa*, Benth.) gave 37% of well-digested pulp, which furnished a strong grayish brown paper, and which could only be bleached to a pale cream color. In 6 hr. *Marishiballi* gave 40% of well-digested pulp free from undisintegrated material, which furnished a rather soft, pale brown paper of fair strength, and which was bleached to a cream color by a strong bleaching soln. In 6 hr. *Kautaballi* (*Licania venosa*, Rusby) gave 44% of well-digested pulp, which produced a pale brown, very soft, rather bulky paper of poor strength, and which could only be bleached to a cream color with a strong bleaching soln. In 5 hours *Morabukra* (*Leguminosae*, genus indeterminate) gave 45% of fairly well-digested pulp, which furnished a pale brown paper of good strength but contg. some undisintegrated material and which bleached fairly readily, giving a white paper of good strength and almost free from specks. In 6 hr. *Moraballi* (*Leguminosae-Caesalpiniae*, genus indeterminate) gave 40% of fairly well-reduced pulp, which yielded a pale brown paper of fairly good strength and contg. only a slight amt. of undisintegrated material, and which bleached fairly readily to a pale cream color, almost free from specks.

Hydrogen-ion concentration; its determination and relation to the paper industry.

ARTHUR ST. KLEIN. *Papier-Fabr.* 26, 145-51; *Wochbl. Papierfabr.* 59, 140-7(1928).—Following a general exposition of the subject, K. gives his experiences in boiler plant and water purification work, and a good review of articles bearing especially on pulp and paper manuif. R. H. DOUGHTY

Chemical pulps for paper making and for the manufacture of rayon. M. BROR. *Papier* 31, 291-301(1928).—An address briefly outlining the several pulping processes and discussing the properties of the products obtained from the standpoint of their transformation into various grades of paper or into rayon. A. PAPINEAU-COUTURE

The manufacture of durable paper and causes of its deterioration. L. ARNOULD. *Papier* 31, 431-6(1928).—A general discussion of the precautions necessary in the manuif. of paper which is to be preserved for a long time. A. PAPINEAU-COUTURE

Tracing paper. Some micro-phenomena. JAMES SCOTT. *Paper-Maker & Brk.* *Paper Trade J.* 75, 251-5(1928).—An illustrated description of the microscopical structure of tracing paper as such and after writing on it with soft lead, ordinary writing ink, and Indian ink. A. PAPINEAU-COUTURE

Paper for blue prints. FREDERICK GROVE-PALMER. *Paper Trade J.* 86, No. 18, 59-60(1928); *Paper Mill* 51, No. 21, 26, 28(1928).—A discussion of the properties required of paper for blue prints and of the precautions to be taken in mfg. such paper. The essential characteristics are high folding resistance and tensile strength, and durability. A. PAPINEAU-COUTURE

Determination of opacity and gloss of paper. ANON. *Pulp Paper Mag Can* 26, 425-6(1928).—A detailed description of the proposed official methods of the Tech. Asscn. of the Pulp and Paper Industry. A. PAPINEAU-COUTURE

Some experiences regarding the influence of fiber character and beating upon the strength properties of paper, particularly sulfate paper. GOSTA HALL. KORSNÅS Wood Pulp Mills, Gefle, Sweden. *Svensk Pappers-Tid.* 31, 321-5, 357 61, 393-7(1928).—Better qualities of both sulfite and sulfate paper have been demanded in recent years. The call for better qualities of sulfate pulp dates from the manuif. of kraft paper in the Mississippi district. The Mississippi kraft pulps have a weaker and more brittle fiber than the Scandinavian and Canadian pulps. Pulp and paper made from yellow pine has monopolized the less exacting market and forced Scandinavian kraft pulp to a higher level. The consumption of sulfate pulp in the U. S. is analyzed critically. Increasing interest in paper testing in the U. S. is a contributing factor in the demand for better pulp qualities. International testing methods are in general confusion. To create a testing method which will give uniform results of satisfactory interpretation it is necessary to agree on standards for: (1) the procedure used in converting pulp into paper (defibration, beating and sheet making), (2) the beating condition (degree of beating) of the fiber at which the paper shall be formed and the strength detd. and (3) the strength properties of the paper which shall be used to characterize the strength of the pulp. Some technical men contend that ball-mill beating is not consistent with mill practice. Detns. made by H. on sulfate pulps used in American mills show that the ball-mill tests ranked the various pulps exactly in accordance with the strength of papers made commercially from the pulps. Sweden is perfecting lab. machinery for paper making to be used in strength testing of wood pulp. Tensile strength, bursting strength and folding endurance increase considerably with continued beating, whereas the tearing strength usually decreases slowly. Several graphs bring out the details of their detn. In Europe the tensile strength and in the U. S. the bursting strength are considered a measure of the strength of a paper. These 2 properties usually run as parallel functions of the beating condition of the fiber, although the bursting strength is somewhat more sensitive to changes in beating condition and the brittleness of the fiber. H. analyzes the factors of fundamental importance to the strength of unbleached wood pulp and discusses the relation of α -cellulose content to the strength of pulp. WILHELM SEGERBLOM

Weighing paper pulp. ARNO JAATINEN. *Svensk Pappers-Tid.* 31, 400-2(1928).—To avoid financial losses the pulp plants of Finland have installed Toledo scales in place of the "push weight" scales long in use. The advantages in reduction of friction, greater speed of operation and elimination of errors are pointed out. WILHELM SEGERBLOM

Determination of the combustibility of cigaret paper. SIGURD KÖHLER. *Svensk Pappers-Tid.* 31, 268-71(1928).—By combustibility of cigaret paper is understood the capacity of the paper to burn without a flame, i. e., only by incandescence. The importance of maintaining const. combustibility in papers used in different brands of cigarets led to the development of a method of testing combustibility based upon ignition of the paper in a specially designed app. by means of an electrically heated igniter-rod and measurement of

the size of the hole burned. The igniter-rod consists of a porcelain tube of so-called "pytagorasmass" with an outside diam. of 2.0 mm., around which is wound in a close spiral a chrome-nickel wire. The total length of the wire is 1 m. and the diam. is 0.30 mm. The length of the spiral is 40 mm. The paper is stretched upon a suitable stand and raised against the igniter-rod. A const. elec. current through the spiral detns. the temp. of the rod and consequently the size of the hole burned. A current of 1 amp. for a tension drop of 17.1–17.2 v. between the terminal screws is suitable. The combustibility is gaged by the max. diam. of the hole burned. If the paper burns to the edge of the stand, the min. strength of current required to ignite the paper gages the combustibility. The moisture content within the customary indoor air-dry limits affects the results to only a minor degree. Cuts of the app. used and of the holes in paper of varying degree of combustibility, and a graph relating current strength to size of hole are shown.

WILHELM SEGERBLOM

The theory of rosin size analysis. A. C. DRESHFIELD. *Paper Trade J.* **86**, No. 21, 59–63 (1928).—From a series of tests made on rosin sizes in conjunction with theoretical consideration of the laws of chemistry, especially as applied to the hydrolysis of the salts of weak acids such as abietic acid, the following conclusions are reached: (1) Because of hydrolysis, free rosin extn. tests on size give misleading information. Results obtained by such tests give not only the true free abietic acid, but also the unsaponifiable matter and some rosin hydrolyzed from the combined rosin. These errors are greater with neutral size than with high free rosin size. (2) The results obtained by free rosin extn. tests vary considerably, depending on the exact procedure used, particularly diln. (3) Errors in the free rosin detn. affect the figures reported as combined, whether obtained by direct detn. or by calcn. from total and free rosin. (4) Free rosin by titration gives reliable results capable of being checked and is a measure of the grade of the size. It does not indicate in what conditions the size enters the reaction in the beaters. It has possibilities for development into a method for detg. the ultimate structure of size. (5) Total rosin detns. are unnecessary as sufficiently accurate values can be obtained by calcn. from total solids and Na_2O detns. (6) Na_2O can be detd. accurately. Variations in the Na_2O content of rosin size, even between neutral and high free rosin sizes, can have but little bearing on the practical alum requirements in the beater, because of far greater variations in stock and water conditions. (7) The total solids test indicates the relative strength of the paste. It is of primary importance to the users of rosin size. All the information necessary to the practical consumer in the paper mill can be obtained from simple calcns. based on total solids and Na_2O .

A. PAPINEAU-COUTURE

The importance of hydrogen-ion concentration in the sizing of paper. H. ROSCHIER. *Pulp Paper Mag. Can.* **26**, 639–40, 679–82, 715–7, 745–8 (1928).—See C. A. **22**, 1851.

Cellulose ester composition. RICHARD L. KRAMER (to E. I. duPont de Nemours & Co.). U. S. 1,676,612, July 10. A compn. suitable for making "artificial leather" comprises cellulose nitrate 1 and methylphenoxycethyl phthalate (or laurate) 0.75–2 parts which serves as a softener.

Plastic cellulose ester compositions. OTTO DROSSBACH and OTTO JORDAN (to I. G. Farbenind. A.-G.). U. S. 1,677,753, July 17. Material suitable for making films is formed of a cellulose ester or ether such as cellulose nitrate together with the mono-ethyl ester of maleic acid or other suitable ester of an ethylenecarboxylic acid and a non-aromatic alc. such as dimethyl maleate or a fumaric ester.

Decorating plastic material containing cellulose esters. JOHN H. CLEWELL (to E. I. duPont de Nemours & Co.). U. S. 1,675,642, July 3. A casting dope which may be formed mainly of cellulose nitrate is mixed with flake-like particles such as "pearl essence" and the compn. is cast into sheets, a stack is formed of sheets with intermediate sheets of crinkled plastic material which may be formed of similar compn. and the stack of sheets is welded into a block which may be used for imitation mother of pearl.

Saccharifying cellulosic material. JOHN PERL (to M. M. Cory). U. S. 1,677,406, July 17. Disintegrated wood or similar cellulose material is subjected to the action of a counter-current of HCl gas mixed with diluent cooled inert gas such as fine gases freed from O so that the cooled gas of highest acid content meets the cellulosic material of the highest acid concn. until it contacts with fresh cellulosic material when the gas mixt. is partially exhausted. An app. is described.

Apparatus for making cellulose acetate sheets, etc. ADOLPH ZIMMERLI (to Acetol Products, Inc.). U. S. 1,677,576, July 17.

Artificial silk. HARRY P. BASSETT. U. S. 1,676,003, July 3. Cellulose and Cu hydroxide are dissolved in NH_4OH and pptn. is effected with a bath of 40° Bé. caustic alkali, the material is washed in a caustic alkali soln. of $15-20^\circ$ Bé. and then washed in a caustic alkali soln. of lower strength. An app. is described.

Artificial silk. I. G. FARBENIND. A.-G. Brit. 280,628, Aug. 16, 1926. A coagulating bath maintained at a temp. of $20-30^\circ$ (or even below 20°) is used in making threads, bands or the like from ammoniacal Cu cellulose solns. which are prepd. from wood pulp, straw or grasses. Products of good luster and strength are obtained. Cf. C. A. 22, 3044.

Artificial silk. R. SAITZ and E. POTT (TRADING AS CHEMISCH FABRIK POTT & CO. AND F. POSTPICH). Brit. 280,608, June 17, 1926. A naphthalenesulfonic acid alkylated in the nucleus, such as the condensation products of naphthalenesulfonic acids with iso-Pr or secondary iso-Bu alc., is added to a viscose bath or coagulation bath or to both; salts of these compds. and their condensation products of oxidation also may be used.

Nozzles for producing artificial silk. LEONARD A. LEVY. U. S. 1,676,831, July 10. The diam. of nozzles is tested, during grinding with abrasive, by passing liquid under definite pressure through the nozzle and measuring the quantity passing in a definite time.

Charging and packing pulp digesters. PER A. FRESK. U. S. 1,676,691, July 10. A circulating air current is passed into and out of a digester and a charge of chips is introduced into the air current entering the digester. An app. is described.

Paper pulp. D. R. NANJI. Brit. 280,629, Aug. 17, 1926. Woolly or other cellulosic material is heated with a soln. contg. up to 4% of an alkali such as NaOH at high temp. and under pressure of about 10 atm. for about a half hr. Impure cellulose pulps, bagasse from sugar cane, grasses and the like may be similarly treated and may be preliminarily crushed and treated with a dil. H_2SO_4 under pressure.

"Beating engine" for paper pulp. LEO SHLICK. U. S. 1,675,385, July 3.

Paper making. ROY V. WELDON (to Great Northern Paper Co.). U. S. 1,676,305, July 10. Mech. features.

Centrifugal and other rotary screens for use in paper making. ISAAC L. LAIRD (to Bird Machine Co.). U. S. 1,675,612 and 1,675,613, July 3.

Oscillating suction box for paper-making apparatus. ALONZO ALDRICH (to Beloit Iron Works). U. S. 1,677,128, July 17.

Soaking machine for use in paper making. CHARLES T. CROCKER. U. S. 1,676,636, July 10.

Apparatus for drying webs of paper. R. MARX. Brit. 280,776, March 10, 1927.

Skimming and sedimentation apparatus for cleaning paper stock. CHARLES L. KELLER (to The Richardson Co.). U. S. 1,676,652, July 10.

"Engine" for refining paper stock. HARRY LIEBECK (to Scott Paper Co.). U. S. 1,676,653, July 10.

Paper-crinkling apparatus. WILLIAM A. LORENZ (to The Otaka Fabric Co.). U. S. 1,676,655, July 10.

Making stretchable paper provided with distributed folds. HOWARD G. WIDMER (to Arkell Safety Bag Co.). U. S. 1,676,759, July 10. Mech. features.

Fiber board. WM. M. SHOEMAKER, JR. (to National Vulcanized Fibre Co.). U. S. 1,675,666, July 3. Sheets of cellulosic material are impregnated with a material such as ZnCl_2 soln. and heated to $38-93^\circ$ and then are superposed and united into a composite fiber board. U. S. 1,675,667 relates to an app. for use in this or similar processes.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

Recent investigations on the determination of the stability of smokeless powder. MICHAEL TARLÉ. Manchurian Arsenal, Mukden, China *Bull. Chem. Soc. Japan* 3, 123-7(1928).—A survey of the various methods commonly used. Variable results will be obtained as long as stability is detd. with heated samples. Moreover these detns. have not much meaning because the solvents and H_2O are evapd. at the high temp. used, and the decompn. cannot be compared with the decompn. occurring in storage. Methods analogous to the electrometric titration should be developed.

A. L. HENNE

Explosives and preventive measures. W. GRAULICH. *Chem.-Ztg.* 52, 428-9 (1928).—If the proper precautions are taken, accidents are not more numerous in the explosives industry than in any other industry. The accidents usually are caused by a breaking of the rules by untrained persons. Several examples are given. A. L. H.

Unexpected explosions. W. P. JORISSEN. *Chem. Weekblad* 25, 228-30(1928).—It follows from the work of Schlumberger and Piotrowski (*C. A.* 9, 862) and of White (*C. A.* 16, 4348) that NH_3 air mixts. are explosive between about 17 and 25 vol. % NH_3 , depending on direction of flame propagation, etc. Small amts of illuminating gas or other gases can widen these limits considerably. Recent explosions in Germany are evidence of this possibility. The limits for HCN are 12.75 and 27 vol. %, contrary to a widespread opinion of its innocence. Another occasionally explosive substance is $\text{C}_2\text{H}_2\text{Cl}_2$ (3.3 to 15.3%); C_2HCl_3 may lower the limit for other gases; CCl_4 tends to raise the limit and decreases hazard.

B. J. C. VAN DER HOEVEN

The value of inert gas as a preventive of dust explosions in grinding equipment. HYLTON R. BROWN. U. S. Dept. Agr. *Tech. Bull.* 74(1928).—Thirty explosions in a 20-yr. period resulted in the death of 60 persons and property damage of \$5,000,000. Exptl. work in industrial plants indicates that CO_2 under pressure possesses many advantages over other fire-fighting media because it does not injure metals, fabrics, or food products, does not freeze nor deteriorate and, since it is a non-conductor, can be used to extinguish fires in elec. equipment. CO_2 leaves no residue; this is a distinct advantage, since frequently the residue or damage caused by the extinguishing medium constitutes the greater part of the loss. Distributing pipes leading from compressed-gas storage tanks to likely sources of fire and equipped with quick-acting valves is an ideal installation for fire fighting and fire prevention in grinding plants, mills, etc.

A. P.-C.

Utilization of badan for tanning and dyeing. S. N. IGNATIEV. *J. Chem. Ind. (Moscow)* **4**, 147-50(1927); cf. Sadikov and Yakimov, *C. A.* **22**, 2681.—200 g. of root of badan (*Saxifraga crassifolia*) contg. 7.8% moisture was pulverized, extd. 3 times with hot water to exhaustion of sol. ingredients, and the liquids were evapd. to dryness at 70°. 78.6 g. of reddish brown dry ext. were obtained and were used for expts. which consisted in detg. (1) the tanning capacity, (2) the dyeing properties and (3) the characters of dyestuffs which are extractible. The detn. of tanning capacity was made by the colorimetric method. The degree of tanning capacity of badan ext. is lower by 40-50% than that of pure tannins. To det. the dyeing properties the ext. was used in amts. of 2-3% of the weight of the fabric to be dyed. With cotton fabrics the following mordants were tried: $\text{Fe}_2(\text{SO}_4)_3$ soln., ferri ammonium alum soln.; Fe_2Cl_6 soln. followed by 0.5% NaOH soln. These mordants enabled I. to dye cotton in brown-black, beautiful greenish black, yellow-brown and dark brown colors. To dye wool, at first Fe_2Cl_6 soln. was used as mordant and the fabric was dyed in dark brown color; then, with PbCl_2 soln. as mordant, wool was dyed in light cream color. All the samples dyed with badan ext. by the aid of mineral mordants preserved their resp. colors well in spite of a 5 months' exposure to sunlight and periodic washings. To obtain S dyestuffs a mixt. of 9 g. badan ext., 6 g. flowers of S, 3 g. NaOH, 3 g. Na_2S (free from Fe) and 25-40 cc. water was placed in a porcelain beaker and heated in a sand bath first at 95° for 2 hrs. under stirring, then at 180° for 16 hrs. 13.3 g. of a melt was obtained which was sol. in water, MeOH, EtOH and ether, giving bronzed-brown solns. This melt dyed cotton, with the addn. of Na_2S , in gray and dark gray colors; it dyed wool, with the addn. of CH_3COOH , in beautiful bronzed-brown color. The difference in the colors obtained was due to the presence in the melt of several dyestuffs, the latter having been sepd. by dissolving 20 g. of the melt in water, acidifying the soln. with CH_3COOH and filtering hot. Six g. of black ppt. was thus obtained (first dyestuff), whereas the filtrate, on being evapd., gave 10.5 g. of a dark brown dyestuff (second S dyestuff). The first S dyestuff possessed the property of dyeing cotton in alk. medium in gray; the second dyestuff dyed, in acid medium, wool and silk (but not cotton) in bronzed-brown color. Preliminary expts. were made to obtain a nitrated product from the ext. of badan by introducing in small portions and under stirring 9 g. of the ext. into a mixt. cooled to 0° of 50 g. H_2SO_4 (sp. gr. 1.84) and 24 g. HNO_3 (sp. gr. 1.58). After 30 hrs. of nitration the mass was filtered through asbestos and the solid residue, without washing, was dried. The yellow-brown nitrated product exhibited under the microscope a cryst. structure and was sol. in water and in MeOH and EtOH giving yellow solns. It dyed wool and silk in yellow and yellow-brown, did not dye vegetable fibers. It seems that badan ext. can serve as a source of many new dyestuffs.

BERNARD NELSON

The textile industry. AYRTON NEIVA. *Chimica industria* **2**, 437-9(1927).—An address.

R. D. BUMBACHER

The properties of the new acetate silk (celanese, milanese, aceta, etc.). A. HERZOG. *Kunstseide* **9**, 7-11, 73-9(1927); *Expt. Sta. Record* **58**, 394.—Extensive studies on samples of cellulose-acetate rayon from Germany, England, Belgium and Switzerland showed the av. width of the dry-spun fiber to range between 26.4 and 40.3 μ and of the wet-spun fiber between 17.1 and 23.9 μ . The several sources had rather characteristic cross sections. The dry-spun samples varied between 3 and 5 deniers in fineness, and the sp. wt. averaged 1.33 g. The elec. cond. of this fiber was very slight. Acetone dissolved cellulose-acetate rayon, whereas chloroform caused it to swell, although other rayons are said to be not affected by these reagents. Water caused only a slight swelling. Cellulose-acetate rayon m. 200-300° into an amorphous mass which became brown on further heating. The av. refraction of light by cellulose-acetate rayon was 1.473, the lowest of rayons and other textile fibers, and this rayon was birefringent. Other behavior in relation to light is also described.

Methods of finishing cottons. PAUL F. HADDOCK. *Textile World* **73**, 3909-71 (1928).—An address, describing present procedures and pointing out the need of chem. research.

RUBY K. WORNER

Removal of non-cellulose constituents of cotton in scouring and bleaching of fabric. M. FREIBERGER. *Textile World* **73**, 3971-3(1928); *J. Textile Inst.* **19**, 134-7P(1928).—A review of recent discoveries in the chemistry involved and a discussion of related technical questions. The most important substances to be removed from cotton cellulose are starches, fats, pectins, proteins, pigments and mineral matters, each of which is discussed individually.

RUBY K. WORNER

X-ray investigation of woolen samples. T. D. THREADGOLD. *J. Textile Inst.* **19**, 233-6T(1928).—The exptl. details of app. and tests are given. There was no evidence

for assuming a cryst. structure in the wools and yarns examd. If such structure exists it must be in the form of extremely minute crystallites which are individually too small to give a characteristic x-ray diffraction pattern, or else the lattice spacing const. d. is less than 0.77 A. U. It is highly improbable that wool is truly amorphous. It would appear that the wool fiber consists of an aggregate of extremely small cryst. particles, i. e., is colloidal, for the likelihood of the lattice const. being less than the least value which could have been detected in this investigation is remote. L. W. RIGGS

Soap in its relation to the degumming of silk. II. Factors controlling the process. PROCTER & GAMBLE. *Silk Degumming*, Bull. No. 3, 1928, 20 pp.; cf. C. A. 22, 1857.—The conditions under which silk is degummed are, in general, in need of standardization and strict operating control. From this study the following recommendations for the degumming of silk are made: (1) The water should be absolutely soft, preferably zeolite-treated under accurate control; otherwise softened with soap soln. (2) The soap should closely approach sodium oleate in compn. In dry flake form 20 to 25% soap (corresponding to 28 to 35% fresh bar soap) is an effective and economical range within which to work, (3) Alkali addns. for cutting cost and time are dangerous from the standpoint of weakening and chafing the silk, because of lack of suitable control methods. (4) The temp. should range between 93° and 98° and preferably be controlled by thermostatic regulation. (5) The time of degumming is largely dependent on temp. and soap concn., both of which should be regulated to effect a max. of economy. In practice 20% soap gives satisfactory degumming in 2 hr. (6) Agitation during degumming is a source of chafing and should be kept at a min. (7) Thorough rinsing is an absolute necessity, especially for tin weighting. Several baths of soft, hot water and the use of a low-titer soap provide the most efficient conditions for rinsing. L. W. RIGGS

The Mackey test (HERBIG) 27. Starch sizing (U. S. pat. 1,677,615) 28. Sizing from starch (U. S. pat. 1,677,614) 28. *p*-Cymene studies. X. *p*-Cymylene-2,5-diamine and certain new dyes (WHEELER, BOST) 10.

Dyes. BRITISH DYESTUFFS CORPORATION, LTD., A. SHEPHERDSON and S. THORNEY. Brit. 280,652, Aug. 24, 1926. Bluish gray to black vat dyes are made by successive treatment with hydroxylamine and subjection to alkali fusion of sulfonic acids of benzanthrone or substituted benzanthrone such as those obtained by synthesis from anthraquinone sulfonic acids or by direct sulfonation as described in Brit. 276,766 (C. A. 22, 2470). The sulfonation and treatment with hydroxylamine may be effected in the same H₂SO₄. Examples are given.

Dyes. BRITISH DYESTUFF CORPORATION, LTD., AND A. J. HAILWOOD. Brit. 280,647, Aug. 19, 1926. The vat dye obtained according to example 1 of Brit. 26,690 of 1913 by alkali fusion of naphthalimide is converted into a product that can readily be dispersed in water and easily vatted, by treatment with oleum or a halosulfonic acid at moderate temp. (suitably about 50°) and then pouring on to ice or water. The product may be used for dyeing cotton from a hyposulfite vat at 50-60°.

Dyes. I. G. FARBENIND. A.-G. Brit. 280,637, Aug. 17, 1926. Dyes which give clear greenish blue and reddish blue shades on wool are produced by the interaction of alkyl or aralkylamine, e. g., butylamine or benzylamine, upon 1-amino-4-halo-2-anthraquinonesulfonic acids in the presence of a catalyst such as Cu or a Cu compd., e. g., CuSO₄.

Dyes. I. G. FARBENIND. A.-G. Brit. 280,846, Nov. 18, 1926. The diazo compd. from the aminobenanthrone made by reducing the nitrobenanthrone described in example 2 of Brit. 12,518 of 1906 is treated with alkali xanthates or S compds. of similar

action and the product then further treated with alkali, *e. g.*, by fusion with KOH and alc. A dye is produced which gives fast black on cotton from the vat.

Dyes. I. G. FARBENIND. A.-G. Brit. 280,492, Nov. 15, 1926. Orange dyes of the anthraquinone series are made by treating a 1-acylamino-4-hydroxyanthraquinone with esters such as the halogen hydride or arylsulfonic acid esters of polyhydric alcs. in the presence of acid-fixing substances, *e. g.*, 1-benzoylamino-4-hydroxyanthraquinone may be boiled with *p*-toluenesulfonic acid chloroethyl ester in the presence of calcined soda and trichlorobenzene. The resulting dye can be sepd. by crystn. from PhNO_2 into 2 products. Other examples also are given.

Dye intermediates. FRITZ BALLAUF, FRIEDRICH MUTH and ALBERT SCHMELZER (to Grasselli Dyestuff Corp.). U. S. 1,675,478, July 3. By condensing carbazole-carboxylic acids with dimethylamine, *p*-toluidine or 2-aminocarbazole, etc., and testing the resulting amides with nitrosophenols, indophenols are produced which are reddish blue to blue powders reduced in alk. soln. with hyposulfite and Na_2S to the corresponding leuco compds. and suitable for use as intermediates for producing sulfide vat dyes.

Solid diazo salt. FERDINAND KELLER and KARL SCHNITZSPAHN (to Grasselli Dyestuff Corp.). U. S. 1,677,610, July 17. A compd. of the formula $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{N}_2\cdot\text{SO}_2\cdot\text{C}_6\text{H}_4\cdot\text{Cl}$ is formed by reaction of diazotized *p*-nitroaniline with *p*-chlorobenzene-sulfonic acid. It is an almost colorless sol. powder suitable for use in dyeing and printing. Nitroaniline and other similar compds. also may be used.

***o*-Hydroxyazo dyes.** OSKAR KALTWASSER, HANS OEHREN and HERMANN KIRCHHOFF (to Grasselli Dyestuff Corp.). U. S. 1,676,697, July 10. Dyes are obtained by coupling with a 1-aryl 3-methyl 5-pyrazolone, *e. g.*, the 1-phenyl compd., the 4-toluenesulfonic ester of 7-hydroxynaphthalene-1,2-diazo-oxide-4-sulfonic acid; these dyes form dark powders sol. in water, but insol. in ether and C_6H_6 , and dye wool orange to brown tints which become red to bluish red when chromed.

Monoazo dyes. WILHELM NEELMEIER (to Grasselli Dyestuff Corp.). U. S. 1,676,107, July 10. By diazotization and coupling of compds. such as aniline and *o*-anisidine and 1,8-(or 1,6)-dihydroxynaphthalene-3,6-(or 3)-sulfonate and treatment with *p*-toluenesulfonylchloride, dyes are obtained with red powders, dyeing wool level red shades fast to light and milling.

Monoazo dyes. WILHELM NEELMEIER (to Grasselli Dyestuff Corp.). U. S. 1,676,458, July 10. By diazotization and coupling of aniline and K 1,6-dihydroxynaphthalene-3-sulfonate and heating with *p*-toluenesulfonylchloride, a dye is produced which is an orange-red powder, dyeing wool from an acid bath orange-red shades fast to light and milling.

Trisazo dyes. OSKAR KNECHT and HANS BRUTSCH (to Chemische Fabrik vorm. Sandoz). U. S. 1,676,562, July 10. A diazotized deriv. of the benzene or naphthalene series is coupled with a diazotizable component; the intermediate is diazotized and combined with the same or another diazotizable component, and, then, after further diazotization, is coupled with a 1-arylammonaphthalenesulfonic acid. Dyes thus formed are extremely fast to light and resistant to washing. Various examples are given of dyes producing gray to black shades on cotton.

Sulfur dye. LINCOLN M. SHAFER (to Tower Mfg. Co., Inc.). U. S. 1,675,430, July 3. A dye is prepd. by the reaction of S on *m*- and *p*-diamines such as *m*-toluenediamine and *p*-phenylenediamine and dehydrothiotoluidine which dyes unmordanted cotton in a sulfide bath tan to greenish bronze shades.

Sulfur dye. ERWIN KRAMER (to Grasselli Dyestuff Corp.). U. S. 1,675,498, July 3. Dyes producing orange-brown shades on cotton from baths contg. Na sulfides are formed by heating 2-nitro- or 2-amino-4-acetyltoluidine with S and about 2-8 mols. of benzidine. U. S. 1,675,499 relates to similar dyes produced by heating 3-nitro- or 3-amino-4-acetyltoluidine with S and benzidine.

Sulfuretted dyes. SOC. ANON. POUR L'IND. CHIM. A BALE. Brit. 280,595, Nov. 13, 1926. In producing dyes as described in Brit. 270,348 (C. A. 22, 1692), the aromatic base is omitted and, together with urea, there are used other compds. contg. N which facilitate the sulfurizing process, *e. g.*, semicarbazide, guanidine and its salts, dicyanodiamide, thiourea, NH_4CNS and acetamide. The dyes produced dye vegetable fibers fast indigo blue tints.

1-Methyl-2,5,6-trichloro-3-aminobenzene-4-sulfonic acid. HERMANN WAGNER and BARTHOLOMAUS VOSSEN (to Grasselli Dyestuff Corp.). U. S. 1,677,536, July 17. This compd. is a whitish powder, very sparingly sol. in water, insol. in alc. and ether, sol. in concd. H_2SO_4 and repptd. on diln. with water. It is made, by nitration and reduction, from 1-methyl-2,5,6-trichlorobenzene-4-sulfonic acid and may be used in the manuf. of dyes.

Metal compounds of azo dyes. FRITZ STRAUB, HERMANN SCHNEIDER and JOSEPH SPIELER (to Soc. anon. pour l'ind. chim. à Bâle). U. S. 1,677,534, July 17. 1-Hydroxynaphthalene-5-sulfonamide or other hydroxynaphthalenemonosulfonamides (other than the 1,8-hydroxynaphthalenesulfonamide) are coupled with *o*-hydroxydiazocompds. such as that of 1-amino-2-hydroxynaphthalene-4-sulfonic acid and the products are converted into metal derivs., e. g., by treatment with Cu or Cr compds. These metal derivs. dye wool in an acid bath fast red-violet to blue and dark green tints.

Chromium compounds of dyes. FRITZ STRAUB, GUILLAUME DE MONTMOLLIN and MAX SCHMID (to Soc. anon. pour l'ind. chim. à Bâle). U. S. 1,676,581, July 10. Azo dyes obtained by uniting *o*-hydroxydiazocompds. with 3-methyl-5-pyrazolone are treated with Cr fluoride, formate, acetate, freshly pptd. hydroxide or an alkali chromite or the like, producing compds. which dye wool fast orange or red tints and also suitable for coloring lacquers. Several examples are given. Cf. C. A. 21, 2069, 3133.

Dyeing cellulose esters and ethers. BRITISH CELANESE, LTD., and G. H. ELLIS. Brit. 280,698, Oct. 30, 1926. Cellulose acetate or similar material is mordanted with thiocyanate solns. in which the concn. of the thiocyanate radical is in excess of the theoretical equiv. of the mordant metal. The solns. may be formed by the addn. of thiocyanates of non-mordanting metals such as Na, K or NH_4 to a soln. of thiocyanate of Fe, Al or Cr. Mordanting is expedited so that the fabrics may be treated in a continuous method. After treatment with the mordanting bath, the material is washed with water or treated with a soln. of Na_2CO_3 or the like to hydrolyze the thiocyanate.

Dyeing fibers. ALEXANDER WINOGRADOFF (to Inecto, Inc.). U. S. 1,677,508, July 17. Fibers such as hair, fur or feathers are treated with a soln. of an inorg. iodide such as CdI_2 or LiI where the color is developed by the oxidation of a leuco compd., e. g. *p*-phenylenediamine. The iodide serves to accelerate the dyeing reaction.

Jigger for dyeing fabrics. HENRY GRASSEY. U. S. 1,676,261, July 10.

Apparatus for dyeing hanks with heated circulating dye liquor. P. F. HÖLTZING (TRADING AS HÖLTZING & Co.). Brit. 280,844, Nov. 19, 1926.

Apparatus for treating felt hats, etc., with dyeing, cleaning, mordanting or other liquids. SOC. DES CONDENSEURS DELAS. Brit. 280,489, Nov. 10, 1926.

Phosphate reducer for bottom chrome dyeing. NEIL NEVILLE (to Federal Phosphorus Co.). U. S. 1,675,450, July 3. Na acid pyrophosphate or other suitable pyrophosphate is added to a dichromate mordanting bath to assist the action of the bath.

Identifying label for use on goods to be dyed. OSWALD GUNNELL. U. S. 1,677,475, July 17. Labels are formed of fabric tape of "Celanese" and cotton yarn with the surface mainly composed of "Celanese."

Bleaching and setting colors. EDGEcombe M. JONES. U. S. 1,677,283, July 17. In simultaneously bleaching white goods and incidentally setting any colors present in the goods, the material is subjected to a single boiling treatment in an Fe kier by the action of a soln. formed from Na silicate, oxalic acid, Na bihydrate and Na perborate.

Modifying the dyeing properties of textile materials. CHEMISCHE FABRIK VORM. SANDOZ. Brit. 280,493, Nov. 13, 1926. The dyeing properties of loose cotton or other vegetable textile fibers are modified (so as to destroy their affinity for substantive dyes and render them suitable for use in "effect threads") by treatment with a mixt. of Ac_2O , HOAc and a catalyst such as is used for the prepn. of cellulose triacetate while only allowing the reaction to proceed as far as the mono- or di-acetate stage. Various examples and details are given.

Textile fabrics. F. HOPKINSON and A. B. HENSHILWOOD. Brit. 280,705, Nov. 11, 1926. In making woven or knitted fabrics as described in Brit. 269,980, synthetic fibers of nitrogenous character are used (instead of vegetable fibers as previously used) such as may be obtained from dissolved skins, hoofs, horns or other animal matter and these are spun with animal fibers such as wool, mohair, silk or the like and are cut into lengths similar to the natural fiber with which the artificial fiber is assocd. The artificial fiber may be dissolved out from the composite fabric (e. g., by use of boiling water) leaving a fabric of extremely fine texture.

Washing and purifying artificial threads wound on perforated bobbins. SPINN-STOFFWERK GLAUCHAU A.-G. and H. VOSS. Brit. 280,519, Nov. 12, 1926. The material is freed from adherent particles or decomn. products by use of air or other gas or vapor under pressure or suction; NH_3 or other neutralizing gas may be used and vapors which condense to liquids may be substituted for washing liquids.

Waterproofing fabrics. LEROY SHELLELL and GEORGE B. JACK, JR. (to Jatón Mfg. Corp.). U. S. 1,676,362, July 10. Silk, canvas or other fabric is treated with a solvent for cellulose esters and then impregnated with a dil. soln. contg. cellulose

nitrate or acetate or other ether-sol. cellulose ester of sufficiently low viscosity to coat and impregnate the individual fibers of the fabric without forming a thick surface layer. An app. is described.

Apparatus for impregnating fabrics with pyroxylin, etc. LEROY SEIDELL and GEORGE B. JACK, JR. (to Jaton Mfg. Corp.). U. S. 1,676,363, July 10.

Textile fibers from animal hair and bristles. WILHELM H. SCHWEITZER (to American Lanil Corp.). U. S. 1,677,149, July 17. Material such as "cross bred cardings" is oxidized, *e. g.*, by an acidified $\text{Ca}(\text{OCl})_2$ soln., and then treated with a 0.1–0.15% NaOH soln., washed and dried.

Textile lubricant. JOSEPH J. SCHAEFER, JR. U. S. 1,677,852, July 17. An alkali metal lactate such as Na lactate is used for treating wool in making woolen or worsted fabric.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

The story of paint and varnish. F. C. HOLTON. Sherwin-Williams Co. *J. Chem. Education* **5**, 682–96, 836–45 (1928); cf. *C. A.* **22**, 2669. R. H.

Large-scale titanium pigment production based on old laboratory process. BRUCE K. BOWEN. *Chem. Met. Eng.* **37**, 427–8 (1928).—The manuf. of TiO_2 from ilmenite, with copperas as a by product, is described. E. H.

Whiting from zinc containing cadmium. I. E. ADADUROV. *J. Chem. Ind. (Moscow)* **4**, 326–7 (1927).—In the manuf. of white pigments from Zn of American origin trouble was experienced on account of yellow coloration of the product obtained. This coloration is entirely due to formation of CdO because of the presence of Cd in the Zn. Analyses of American Zn show in one case the presence of 0.37% and in another case of 0.84% Cd, whereas German Zn contains no trace of Cd. On calcining the pigment obtained from American Zn, yellow coloration is apt to disappear on account of formation of CdCO_3 , which is white. Pure CdO, on being calcined at 600° in a current of CO_2 , does not whiten, in presence of ZnO, however, whitening takes place with formation of CdCO_3 , which is attributed to the catalytic action of ZnO. If the calcination is effected above 800 – 900° , CdCO_3 dissociates with formation of CdO and consequent reappearance of yellow coloration, which cannot be eliminated by further calcination. The best way of treating this overcalcined whiting is to mix it with small quantities of chalk in an atm. of CO_2 at 800 – 1000° , under these conditions CaCO_3 partly decomposes and CdO becomes carbonated and white. BERNARD NELSON

Influence of the iodine number on the quality of linseed-oil varnish. Z. TALANZEV. *Oil and Fat Ind. (Russia)* **1928**, 17–8; *Chem. Zentr.* **1927**, I, 819.—Various cases (hemp, poppy, sunflower and cedar oils) are cited to show that, like linseed oil, many vegetable oils with low I nos. give more quickly drying varnishes than do those with high I nos. Sunflower and cedar oils in general give varnishes which do not dry completely but which remain sticky for a long time. By maintaining oils at -25° and subsequently filtering, varnishes prepd. from them dry much more rapidly. Thus oil chilled in this way dried in about 3 hrs., compared with 9–10 hrs. for the corresponding unchilled oils. Though such chilling and filtering increase the rate of drying of semi-drying oils (sunflower and cedar oils) and make the drying more nearly complete, they do not dry completely even after this treatment. C. C. DAVIS

Spontaneous ignition of varnish. Z. TALANZEV. *Oil and Fat Ind. (Russia)* **1926**, No. 7–8, 62–4; *Chem. Zentr.* **1927**, I, 1384.—Two instances of the spontaneous ignition of varnish and of linseed oil are described. In the 1st case, a bale of oakum satd. with varnish spontaneously ignited; in the 2nd case clothing which was satd. with linseed oil and which dried in proximity to a steam boiler also ignited spontaneously. On the other hand it is maintained that straw impregnated with linseed oil or with varnish will not ignite spontaneously. There should be no hesitation, therefore, in shipping linseed oil and varnish in wooden casks covered with straw for protection. Far more dangerous than linseed oil or varnish is linseed meal, which in large bulk easily ignites spontaneously. Even flaxseed itself readily ignites spontaneously when piled in heaps, and to prevent spontaneous heating it must be frequently turned. The same is true of extd. seed, whereas oil cake is not dangerous when it is not piled flat. C. C. D.

New rust-preventing varnish. M. B. *Apparalebau* **40**, 140 (1928).—"Enamit" protects containers from C_6H_6 , benzine, alcohols, oils, etc. J. H. MOORE

Finishing modern aircraft. R. C. MARTIN. *Chem. Met. Eng.* **35**, 404–5 (1928).—

The application of cellulose-ester dopes to airplanes and to dirigible balloons is discussed.

E. H.

A compilation of patent literature on the manufacture of synthetic resins. ALADIN. *Kunststoffe* 17, 278-83 (1927); cf. C. A. 22, 142.—Patents referring to the manuf. of synthetic resins up to the end of 1926 with the exception of the phenol condensation products are classified in the following manner: (1) from hydrocarbons, (a) coumarone resins, (b) vinyl resins, (c) other resins; (2) from hydrocarbons and aldehydes; (3) from Cl compds. by splitting off HCl; (4) from naphthalene and benzyl chloride; (5) from naphthalene and oxalic acid.

BONIFANT HAMILTON

Fusing and dissolving the "infusible" and "insoluble" resinoids. CHARLES W. RIVISE. *Plastics* 4, 309-10 (1928).—A review of patents on treatment of phenol-aldehyde resins for reworking.

G. B. TAYLOR

Mechanical properties of resinoid plastics. Colloid chemical aspects of condensation products. O. MANFRED AND J. OBRIST. *Plastics* 4, 318-21 (1928).—See C. A. 21, 2991.

G. B. TAYLOR

Synthetic resins. A. A. DRUMMOND. *Elec. Rev.* (London) 102, 59-60; (1928); *Science Abstracts* 31B, 189.—The resins are prepd. from formaldehyde, phenolic resins, acrolein resins, glycerol and phthalic anhydride resins, and hydrocarbon resins. Methods of classification by the raw materials used by the heat-resisting properties and by soly. in certain org. compds. are described. The chief uses are in the manuf. of molded compns. of an inert material with the resin as a binder, and for laminated products made from textile fabrics coated or impregnated with the resin. The elec. strength varies from 450 to 1000 v. per mil. The most commonly used resins are those derived from formaldehyde (bakelite type) and those derived from phthalic anhydride (glyptal type), the latter being used instead of shellac for building up mica sheets. Synthetic resins in general are superior to rubber, where exceptional resistance to heat and chem. influence are required, and also give a better appearance and lasting stability.

H. G.

The chief constituents of the rosin light oil. II. SATOYASU IYMORI AND TADAO ISONO. *Bull. Inst. Phys. Chem. Research* (Tokyo) 7, 89-97 (1928).—The chief constituent of the rosin light oil obtained by destructive distn. of rosin with Japanese acid earth is methylpentamethylene. By means of a H_2SO_4 treatment, 2 satd hydrocarbons have been isolated therefrom, one of which, b. 140-5°, d_4^{20} 0.7844, n_D^{20} 1.4332, is hexahydropseudocumene, while the other one, b. 131-2°, d_4^{20} 0.7822, n_D^{20} 1.4233, is considered an isomeric form of the first one and could not be identified. A. L. HENNE

Some useful matters contained in forest trees in Japan [tung oil] (Miura) 22. Benzylcellulose and its uses [for lacquers] (CLEMENT, RIVIERE) 23.

AABYE, J. S., AND NEERGAARD, A. N.: **Hvide Farvestoffer til udvendig Oliemaling.** Copenhagen: Teknologisk Institut. 30 pp.

Composition containing oil and nitrocellulose. WALTER D. BALDSIEFEN AND THOMAS H. ROGERS (to E. I. duPont de Nemours & Co.). U. S. 1,675,631, July 3. A compn. suitable for use as a coating contains nitrocellulose, a vegetable oil such as castor oil and an aromatic amine, e. g., diphenylamine, which serves to prevent rancidity.

Conditioning printing ink. LESLIE W. CLAYBOURN. U. S. 1,675,695, July 3. A drier such as japan drier or Pb acetate is stirred with previously made printing ink just before the ink is used.

Hood and draft conduit for controlling fumes from varnish kettles or similar apparatus. VERN K. BOYNTON (to Perry & Webster, Inc.). U. S. 1,675,403, July 3.

Resinous composition. VICTOR H. TURKINGTON (to Bakelite Corp.). U. S. 1,677,417, July 17. A resinous compn. which may be used for varnish, impregnating, etc., comprises a phenol-fatty oil-methylene reaction product such as that formed from phenol, tung oil, CH_2O and $(CH_2)_3N_4$ together with a sufficient proportion of colophony or other non-phenolic resin to serve as a blending agent and prevent sepn. of insol. reaction products.

Solvent oil from resinous material. SATOYASU IYMORI AND KOJI SUZUKI (to Zaidan Hojin Rikagaku Kenkyujo). U. S. 1,675,977, July 3. In prepg. a solvent oil suitable for use in fuels, etc., from colophony or similar resinous material present in coniferous wood, the material is mixed with an "acid earth" or the like and heated to about 500° until decompn. is effected.

Synthetic reins. H. L. BENDER (to Bakelite Corp.). Brit. 280,520, Nov. 10, 1926. PhOH or other suitable phenol is caused to react with more than 1 mol. proportion of CH_2O and at least part of the excess CH_2O is then combined with a non-phenolic substance such as urea also capable of forming resinous products; in the second stage of this process, the mass may be rendered acid by lactic, boric, phosphoric or other suitable acid. Thiourea or toluene-*p*-sulfonamide may be used instead of urea, and the product may be dissolved in alc. or other suitable solvent to form a varnish or may be further heated to render it insol. and infusible and may be used in molding mixts., etc. Brit. 280,521 specifies the manuf. of synthetic resins by condensing a phenol with anhydroformaldehyde aniline (or the corresponding deriv. of another cyclic amine) or with reagents such as CH_2O and aniline (or other suitable cyclic amine). Examples are given in which $(\text{CH}_2)_6\text{N}_4$, a filler such as wood flour and other reagents and addns. may be used.

27—FATS, FATTY OILS, WAXES AND SOAPS

R. SCHERUBEL

Analysis of fats by the iodine method. EUGENIO LINDENBERG. *Bol. soc. chim. S. Paulo* 1, 92(1928).—The Margosches method is described (cf. *C. A.* 18, 2436). To dissolve certain fats not easily sol. L. recommends an addn. of 1–2% of HCl to the alc.; solid fats are first heated with alc. and after cooling to 25°, treated with the 0.2 N I soln.; 0.5 to 1 cc. of CHCl_3 may be added with advantage to the fat or to the alc.

R. D. BUMBACHER

Tests for the incipient rancidity of fats. W. L. DAVIES. *J. Soc. Chem. Ind.* 47, 185–7T(1928).—A survey is given of the more important tests for following the course of autocatalytic oxidation of fats. The Kreis test is not an indication of the degree of rancidity but of the amt. of 3-membered C chain compds. capable of coupling 2 mols. of phloroglucinol to form a flavonium salt. A test which can forecast the keeping qualities of a fat is as follows: 1 g. of fat and 1 cc. of 0.25% methylene blue are emulsified in 10 cc. of 50% dild. sepd. milk, and the blue color is allowed to be bleached by the reductose of the milk by incubating at 37° to 40°. After bleaching the contents of the tube are well shaken and the depth of blue color is noted. The test was carried out on a large no. of fats of known history and keeping properties and the depth of the blue formed corresponded accurately with the ease of oxidation of the fats. The test is useful in detecting metallic contamination of fats and was used in compounding the catalytic action of Cu and Fe in the oxidation of butter fat. Further, as a test for the state of oxidation in individual fats, this method was found more suitable than the Kreis test and less cumbersome than detg. the oxidizability values of the steam vol. and H_2O -sol. constituents.

R. SCHERUBEL

Maritime fats and their production in the northern part of the Soviet Republic. I. SHENDEROVICH. *Oil and Fat Ind.* (Russia) 1926, No. 6, 18–22, No 7–8, 17–21; *Chem. Zentr.* 1927, I, 2868.—Maritime fats, especially seal oil, are obtained and are worked up in the most primitive way in Russia, and because of the poor quality of the final products, the latter are used exclusively for oiling leather and in the shoe industry. Detailed instructions are given for obtaining fats and for purifying, decolorizing and deodorizing the fats. By the process described, which is based on modern European methods, a product suitable for the production of margarine or other food product can be obtained.

C. C. DAVIS

Some extraction experiments in the laboratory. A. W. Seifensieder-Ztg. 55, 119 (1928).—Lab. results are diagrammed for the extn. of earthen, press cakes and seeds, by shaking 50 g. of the material with 50 cc. solvent 3–5 times and then extg. to exhaustion. The following materials were tested: bleaching carbon, soy earth, oil earth, hardened fat earth, castor bean cake, palm kernels, sunflower seed, soy beans and cacao cake.

P. ESCHER

The Mackey test [for inflammability of textile oleins]. W. HERBIG. *Seifensieder-Ztg.* 55, 118–9(1928); cf. *C. A.* 21, 499. —Polemical.

P. ESCHER

Some results in the hydrogenation of fats during the last three years. Y. SORENSEN. *Oil and Fat Ind.* (Russia) 1926, No. 4–5, 54–7; *Chem. Zentr.* 1927, I, 2868.—Ni catalyst used in the hardening of fats can be used repeatedly without regeneration. To accomplish this, the catalyst which settles before filtering the hydrogenated fat is pulverized and is mixed with an equal quantity of fresh catalyst for the new reaction. This mixt. is just as active as the freshly prepd. catalyst. The catalyst remaining on

the filter press is not usable, since it is rendered inactive by slimy and protein impurities in the fat.

C. C. DAVIS

Acid salts of fatty acids. I. STENZENKO. *Oil and Fat Ind.* (Russia) 1926, No. 7-8, 27-38; *Chem. Zentr.* 1927, I, 1426.—The problem of the existence and constitution of acid alkali salts of fatty acids was investigated. The prepn of the acid K salts by hydrolysis of the corresponding neutral salts is inconvenient on account of the great diln. necessary. Partial neutralization of the fatty acids in EtOH with alc. KOH was, therefore, chosen as a method of prepn. The acid salts were readily crystd. from their alc. solns. and after filtration and drying at 10-5° were practically pure. The combined acid in excess of that represented by the formula KR (R is the fatty acid residue) was detd. by titration of the alc. soln. with KOH (phenolphthalein). The following compds. were isolated, the data giving the m. p. and the no. of cc. of 95% EtOH to dissolve 1 g. of acid salt, resp.: *K disearate*, 153°, 880; *K dipalmitate*, 138°, 198; *K dimyristate*, 153°, 76; *K dilaurate*, 160°, 36; *K dioleate*, 95°, not detd. The method of prepn. always gave salts of the type HR.KR. Expts. aimed at the prepn. of mixed acid salts of the type HR₁KR₂ were unsuccessful. Instead, the reaction $2HR_1 + 2KR_2 \rightarrow HR_1KR_1 + HR_2KR_2$, led to the formation of the simple acid salts, and since the soly. diminishes with increase of the mol. wt. of the acid, the salt of the acid with the higher mol. wt. always crystd., leaving the other acid salt in soln. Water hydrolyzes the acid salts, and the greater the mol. wt. the greater this tendency to hydrolyze. Whereas K dioleate hydrolyzes appreciably at room temp. hydrolysis of the other acid salts begins only at 40-50° and with the dilaurate is hardly noticeable even at 100°. Extd. in a Soxhlet app. for 70 hrs., the acid salts give up nearly all their fatty acid constituent, leaving as residue the neutral salt.

C. C. DAVIS

The decolorization of coconut oil. P. HONIG. *Allgem. Öl Fett Ztg.* 23, 571-3 (1926); *Chem. Zentr.* 1927, I, 1384.—To det. the color, an empirical scale was used, No. 1 of which was the color of 0.001 N K₂Cr₂O₇ and No. 100 the color of 0.1 N K₂Cr₂O₇. Tables are given for comparison of K₂Cr₂O₇ values with the same colors of the Lovibond tintometer. It is shown by means of diagrams and tables that pure coconut oil treated with highly activated C (e. g., Norit) mixed with 20% activated fuller's earth is the economical means of obtaining a clear, white, stable oil. Traces of fuller's earth in the refined oil increased its content of free acid during 72 summer days from 0.03% to 0.42%. Extn. from the earth-C mixt. is conveniently carried out with benzine. If a subsequent extn. with acetone is made, Norit with 80% of its original decolorizing power is obtained.

C. C. DAVIS

Properties of cacao butter; the detection of foreign fats in chocolate. D. ALBERS. *Chem. Weekblad* 25, 235-9 (1928).—The critical point of sepn. of aniline-cacao butter mixts. was found for pure cacao butter at 80° aniline from 42.7° to 43.2°; for the possible adulterants "illipé" fat 33.3°, Borneo tallow 19.6° (90% aniline), cacao-shell butter (acidity 34.6°) 35.0°. The sepn. point for shell butter depends greatly on its acidity, being 41.1° for acidity zero and 35.0° for acidity 34.6. Likewise cacao butter mixts. show about 0.18° drop in sepn. point per degree increase of acidity. Linear interpolation for sepn. points of mixts. of cacao butter with foreign fats is allowable as shown from expts. Three distinct melting points of cacao butter were observed. Fat melted in a U-tube and then solidified under tap water m. 23.8°; a second m. p. is found by the Polenske method after 24 hrs. (29.0°); a third after 6 to 10 days' standing (33.6°). The last one can be accelerated by inoculating 5 g. molten fat at 30° with 5 mg. solid powdered fat of normal m. p. and 24 hrs.' standing in the icebox. For pure cacao butter both m. ps. are clearly visible in the same sample after it is left overnight at 22° and then heated up according to Polenske, 2° per 5 min. In mixts. the double m. p. disappeared. The refraction of cacao butter at 40° is around 1.4570, the I no. (Winkler) between 34° and 36°, the I no. of its fatty acids 36° to 38°, the m. p. of these 48° to 49°. From chocolate the fat was sepd. by boiling with HCl and after filtration, washing and drying, extn. with C₂HCl₃. After neutralization of the fat if necessary the values of 16 samples for the consts. were found to lie within the limits found for pure cacao butter. Of several samples with abnormal values the probable adulteration is discussed; sepn. point, refraction and m. p. are the most reliable criteria.

B. J. C. VAN DER HOEVEN

The mechanical treatment of oil palm fruit. A. STIELTJES. *Mem. rapports mal. grasses Inst. Colonial Marseille* 3, 255-67 (1928).—The fruits are first cooked in H₂O, then put through a machine for removing the pulp after which the kernels are pressed either in hydraulic presses, Anderson expellers, or the crushed mass is centrifuged. Extn. can also be used.

E. SCHERUBEL

The presence of free fatty acids in palm oil. A. C. BARNES. *Mem. rapports mal.*

grasses Inst. Colonial Marseille 3, 269-87 (1928).—The ripe oil-palm fruit can be kept in a cool, dry, well-ventilated place for 7 to 9 days without any great increase in free acid. The free acid increases more rapidly in the picked fruit than in that which ripens and falls. This is more marked in unripe fruit than in ripe. The enzymes secreted by mold formation are able to hydrolyze the oil in the pulp. During the period of storage in casks hydrolysis continues if active enzymes are present. If the particles of vegetable matter are removed from the oil, hydrolysis diminishes. Hydrolysis is completely prevented if the oil is heated to 110° and filtered. The action of the enzyme in the pulp from the nut is completely checked if the fruit is heated for 10 min. in H₂O at 55°. Certain chem. products such as NaCl and tannic acid modify the activity of the enzymes in palm nuts.

E. SCHERUBEL

Behavior of oils under ultra-violet light. R. MARCILLE. *Ann. fals.* 21, 189-97 (1928).—Fresh virgin olive oil when examd. under ultra-violet light through a Wood screen has a light yellow color, sometimes highly opalescent; under the same conditions second-pressing oil has more of an orange color, which can even be brick red with very low-grade oils. On aging of the oil the color becomes either grayish white or lilac, while aged low-grade oils exhibit a more or less marked violet-blue fluorescence, which at times may equal that of seed oils. A study of the causes of these phenomena showed that the violet fluorescence of olive oils is accidental and is due to oxidation or to the action of heat, and that it is particularly marked in refined oils obtained either by pressing or by extn. With seed oils the violet fluorescence is natural in some cases, but in most cases results from the treatments they have undergone in the course of extn. or refining. This property cannot therefore be considered as an abs. characteristic of either group of oils. In practice, the use of ultra-violet light can furnish valuable indications for the preliminary examn. of olive oils; but even those having a normal reaction cannot be absolutely considered as pure, nor does an abnormal reaction positively prove adulteration. In the latter case, if chem. analysis gives normal consts and shows the absence of adulterants, if the acidity is high (over 3%) the oil is probably pure but of low grade, while if the acidity is low the oil is probably a pure refined olive oil. But the latter can also have been mixed with oils of high acidity, so that the interpretation of the results then becomes extremely difficult.

A. PAPINEAU-COUTURE

The decolorization of oils with fuller's earth. J. DAVIDSOHN. *Oil and Fat Ind.* (Russia) 1926, No. 7-8, 10-7; *Chem. Zentr.* 1927, I, 1537.—Following a brief survey of the production of fuller's earth, a comparative classification of earths based on their decolorizing power is given. The decolorizing power was detd. by the method of Eckart and Wirtzmüller (*Die Bleicherden*, 1926). The decolorizing factor varied from 1.18 (American fuller's earth) to 7.78 (Silhydrol) and 8.03 (Isarit), other earths lying between these extremes. The measurements were made on products of 1924 and with soy-bean oil. For oil satn. values, reference is made to data already published (*Seifensieder-Ztg.* 50, 665). Expts. on the fixation of acids by fuller's earth indicated a slight alk. reaction of the earths. An increase of the acid no. of oil during decolorization with fuller's earth does not therefore occur. Regeneration of fuller's earth by heating is possible only after completely extg. the oil, and in the purification the earth loses approx. 1/3 of its decolorizing power. Removal of oil is usually carried out through the agency of hot water or superheated steam, but this method does not thoroughly remove oil from the earth. It is recommended that the oil be sapond. with aq. NaOH (30° B_e), the soaps which contain fuller's earth then being mixed with other soap. C. C. D.

Adsorptive capacity of various decolorizing agents. A. M. MONOSON. *Papers Karpov Chem. Inst. Bach. Memorial Vol.* 1927, 169-73.—In the manuf. of ceresin the resins which are formed by treatment of ozocerite with H₂SO₄ are responsible for the appearance of a dark coloration and have to be removed by various decolorizing agents, such as floridin, fuller's earth, clays, silicas, charcoals, etc. To find the most suitable agent a study of the resin-adsorptive capacity of different agents under different conditions has been undertaken. Russian clays are apparently as effective as those of foreign origin and they can be used to advantage not only to discolor ceresin but also in the industry of animal and vegetable *fats and oils*. Preliminary pulverization of the adsorbers strongly increases their adsorptive power, and so does sometimes their treatment with acids. The most favorable temp. for drying adsorbers is 350-400°. Calcining adsorbers at high temp. does not improve them, whereas drying them at 105° even has a deteriorating effect.

BERNARD NELSON

Some sterols of the vegetable kingdom. KURT BONSTEDT. *Z. physiol. Chem.* 176, 269-81 (1928).—The crude phytosterol from soy-bean oil was brominated according to the method of Windaus and Hauth to effect a sepn. of stigmasterol and sitosterol. The stigmasterol content amounted to 25%, and the sitosterol obtained by reduction

of the readily sol. bromide appeared to be identical in all its properties with the sitosterol from wheat germs. Attempts were then made to prep. derivs. which would not be isomeric but identical with the corresponding cholesterol derivs. Heating 8 hr. in a sealed tube at 220° with Ni catalyst converted it into sitostanone which on oxidation yielded the same dicarboxylic acid as that prepd. from sitosterol. Addn. of HCl to sitostene in CHCl₃ soln. yielded *sitostene-HCl*, m. 132-3°, and this by boiling with alc. KOAc was converted into a *pseudositostene*, C₂₇H₄₆, m. 69°. Sitosterol forms a cryst. addn. product with HCl, which m. 155° with decompn. The analysis of this deriv. was not quite in agreement with the calcd. values, suggesting the presence of the dihydro-sitosterol obtained by Anderson (*C. A.* 18, 2134) from the endosperm of maize. By repeated recrystns. the m. p. of sitosterol remained practically const. but the *l*-rotation diminished very noticeably. From 50 g. crude sitosterol 0.4 g. dihydro-sitosterol, m. 144°, [α]_D 28°, was actually isolated. Repeated fractionation of the acetylated mother liquors gave an acetate, m. 143°, [α]_D -46.8°, which on sapon. yielded a sterol, m. 142°, [α]_D 44.8°. This differed considerably from Anderson's γ -sitosterol in m. p. and rotation, but had the same m. p. as the sterol obtained by Windaus and Welsch from beet oil, although a 10° difference in rotation. B. prepd. this beet-oil sitosterol and by numerous recrystns. lowered the rotation 5° without changing the m. p. Fractionation of the acetate, on the other hand, raised the m. p. 8° with very little change in rotation. Other derivs. prepd. from the γ -sitosterol of soy-bean oil were *sitostanol*, m. 143-4°, [α]_D¹⁶ 20.8°; by hydrogenation with Pd black; *sitostanol acetate*, m. 144-5°; *sitostanone* m. 163°, [α]_D¹⁵ 38°, by oxidation of sitostanol; *sitostane*, m. 87°, [α]_D¹⁵ 20.2°, by Clemmensen reduction of the ketone; *sitosteryl chloride*, m. 115-6; *sitostene*, m. 73°, [α]_D¹⁹ -59.2°, by reduction of the latter with Na and AmOH. Sitosterol is evidently an almost inseparable mixt. of several sterols which form mixed crystals. A. W. DOX

The use of sodium hydroxide in the preparation of catalyst for hydrogenation. E. MASHKILLEISSON. *Oil and Fat Ind.* (Russia) 1926, No. 4-5, 53; *Chem. Zentr.* 1927, I, 2868.—When on account of lack of Na₂CO₃, Ni catalyst for the hardening of fats must be pptd. with NaOH, the catalyst is less active than that prepd. with Na₂CO₃. This is attributed to the greater difficulty of washing out NaOH from the pptd. Ni(OH)₂, so that in the subsequent heating of the Ni(OH)₂ for the purpose of reduction, Na silicate forms and partially envelops the Ni. Furthermore the catalyst prepd. from NiCO₃ has a greater surface area, because of the swelling effect during the escape of the CO₂. The use of NaOH instead of Na₂CO₃ in the prepn. of Ni catalyst is therefore to be avoided.

C. C. DAVIS

Hydroxycitronellal in the soap industry. FELIX COLA. *Riechstoffindustrie* 1926, 201-22; *Chem. Zentr.* 1927, I, 822.—Hydroxycitronellal is an excellent ingredient for lilac, lily-of-the-valley, jasmine and other flower compns. and is used extensively in the perfumery industry. Though so well adapted to the latter industry, it is unsuitable in the soap industry, for like its derivs. it decomp. rapidly in soap, forming a rancid oily odor. According to expts. of C., this decompn. in soap paste can in many cases be prevented by combining hydroxycitronellal or its derivs. with the same quantity of methylanthranilate. Under these conditions an odor between sweet pea and furze is obtained. The application of such mixts. is illustrated by a formula. C. C. D.

The washing quality of soap. B. RAVICH. *Oil and Fat Ind.* (Russia) 1926, No. 6, 28-31; *Chem. Zentr.* 1927, I, 2868.—A survey is made of theories of washing, and recent views on the compn. of soap having a max. washing power are discussed. Such a soap must be as neutral as possible and should contain the highest practicable proportion of fatty acids of high mol. wts. Unsats. acids give soaps with less washing power than do satd. acids.

C. C. DAVIS

The influence of fat constants in a soap charge upon the hardness and solubility of the soaps. E. L. LEDERER. *Seifensieder-Ztg.* 55, 85-7 (1928).—Webb's method of calcg. the hardness and soly. of a soap from the difference of the sapon. no. and I no. (*I N S* factor, cf. *C. A.* 22, 879) holds true for such types as W. selected for illustration, but fails entirely for Marseilles curd soaps, which contain no non-drying fats; 14 examples of such fat charges are given and while the calcd. hardness approx. agrees in a few cases with actual figures, the calcd. soly. does not agree. A knowledge of the dependence of the *permanation coeff.* (cf. *C. A.* 20, 3829) upon the chem. constitution of the fats might lead to more dependable data.

P. ESCHER

Discoloring soap. A. RIZZINI. *Chimica Industria* 2, 420-2 (1927).—A general description is given of the methods used in discoloring soap. R. D. BUMBACHER

Washing powder. W. SHADIN. *Oil and Fat Ind.* (Russia) 1926, 10-23; *Chem. Zentr.* 1927, I, 822.—A survey of washing agents and soap powders now used in Russia

shows that in general they are of poor quality and are for the most part mixts. of Na_2CO_3 and worthless ingredients. Thus "Ukrainka" contains 99.1% Na_2CO_3 ; "Chosjaska" 26.8% Na_2CO_3 , 39.4% NaCl and 33.0% water; "Gloria" 11.8% Na_2CO_3 , 41.8% Na_2SO_4 and 46.6% water, and "Stirol Inosit" 1.4% fatty acids, 52% Na_2CO_3 , 6% water-glass and 40.6% water. Na perborate is not manufactured in Russia, and pure soap powder is available in insufficient quantities. In conclusion the most commonly used machines for producing soap powder are described. C. C. DAVIS

Experience and observations on apparatus for saponification under pressure. C. H. KRUTGEN *Chem. App.* 15, 133-6 (1928).—A rather detailed description of app. and method of operating in an English soap factory. J. H. MOORE

Soap in its relation to the degumming of silk. II. Factors controlling the process (Procter & Gamble) 25. Some useful matters contained in forest trees in Japan [fatty oils] (MIURA) 22. The manufacture of corn starch and obtaining the residue and the corn oil (KRIZKOVSKY) 28. Synthetic fixators for perfumery (POUCHER) 17.

DAVIDSOHN, J.: *Lehrbuch der Seifenfabrikation*. Berlin: Gebrüder Borntraeger. 731 pp. R. M. 36.

Detergent. THOMAS MOSS. U. S. 1,677,044, July 10. A mixt. of equal quantities of soap and $\text{Na}_2\text{S}_2\text{O}_4$ is used for laundry purposes, etc.

28—SUGAR, STARCH AND GUMS

F. W. ZERBAN

Modifications of sucrose. E. O. VON LIPPMANN. *Chem.-Ztg.* 51, 873 (1927).—Previous indications that sucrose may exist in several modifications are confirmed by the recent work of Helderman (*C. A.* 22, 705), showing that sucrose pptd. by MeOH has sp. gr. 1.5713, while that pptd. by EtOH has sp. gr. 1.5860. The heats of soln are -813 and -1095 cal., resp. The 2nd modification is more stable at moderate temp. (30°). All phys. consts. of sucrose published so far apply to undefined mixts. of its 2 or more modifications. F. W. ZERBAN

Detection and estimation of sucrose by the ammonium molybdate method. NORRIS W. MATTHEWS. *Maryland Acad. Sci. Bull.* 7, No. 3, 35-7 (1928).—To detect and det. sucrose in very dil. solns. such as condenser water in sugar factories, 5 cc. of the liquid to be tested is placed in a clean test tube, 3 drops of concd. HCl and 3 cc. of a 4% NH_4 molybdate soln. are added, and the tube is placed in a boiling water bath for exactly 6 min. If sugar is present a blue color develops, which is, however, not permanent. For quant. work standards are prepd. by dilg. a soln. contg. 1 g. pure sucrose per l. to convenient concns, and treating these solns. exactly as described for the test. Permanent standards may be made by dilg. blue-black ink to match the freshly prepd. primary standards. For concns. below 0.0125% of sucrose, dil. felding soln. must be used instead of ink to get a perfect color match. These secondary standards keep for 6 months. The conditions of the test must be strictly adhered to in quant. work, because even slight variations in detail may cause large errors. F. W. ZERBAN

The new baryta process in the manufacture of beet sugar. PAUL RIMAILHO. *J. fabricants de sucre* 1926, 15/5; *Chem. Zentr.* 1927, I, 195.—The new process overcomes the difficulties encountered in the decompn. of BaCO_3 , by means of a simple app. ("Paul Baud" process). BaCO_3 is heated in a rotary furnace not above 1150° with a mixt. of oxides, especially Fe_2O_3 . A kind of ferrite in the form of black pellets of the size of beans is obtained, which with water disintegrate with evolution of heat. The product is filtered and washed, a soln. of pure Ba(OH)_2 thereby being obtained. The filtration proceeds smoothly and the filter cake can be used again. C. C. DAVIS

The losses of sugar in the storage of sugar beets. I. I. DOKHLENKO. *Zapiski* 4, 77-86 (1926); *Expt. Sta. Record* 58, 432-3.—The investigation dealt with the control of the losses of sugar in sugar beets in storage, the loss in weight, the change in compn. of N compds., and other aspects of the storage problem. The results led to recommendations that areas infested with disease should be isolated and infected beets be destroyed to control the disease. A clean cut at the crown perpendicular to the axis will permit examn. for diseases. Infested fields should be plowed and seeded to some grain crop, and all litter in connection with the storage should be burned. It appeared advisable to det. the maturity of the beets before digging and to keep unripe beets separate.

Sprinkling the pits with Fe sulfate before storage of beets and maintaining a const. storage temp. are also suggested. H. G.

Acids of maple sugar "sand." E. K. NELSON. U. S. Dept. Agr. *J. Am. Chem. Soc.* 50, 2028-31 (1928).—Maple sugar "sand" is the deposit of the Ca salts of org. acids, chiefly Ca malate, which forms in the evap. kettle during the concn. of maple sap. The acids identified were: *l*-malic, formic, acetic, fumaric, succinic and citric; there was evidence of the presence of *d*-tartaric and tricarballic acids. A small quantity of an unknown acid, represented by a hydrazide, m. 173-5°, was found. C. J. W.

Acids of maple sirup. E. K. NELSON. U. S. Dept. Agr. *J. Am. Chem. Soc.* 50, 2006-8 (1928).—The approx. quantities of acids found in a sample of maple sirup from Vt. and Mich. in g. per l. are: formic, 0.134, 0.121; acetic, 0.150, 0.085; *l*-malic, 1.04, 0.81; citric, 0.095, 0.11; fumaric, 0.0056, 0.0063; a small quantity of succinic acid was found in the Mich. sample. There was evidence of the presence of a small quantity of an unidentified acid having a high m. p. Neither *d*-tartaric nor tricarballic acid could be found. C. J. WEST

Influence of humidity on the elastic properties of starch film. FREDERICK T. PEIRCE. *J. Textile Inst.* 19, 237-52T (1928).—The effects of humidity on torsional rigidity, flexural rigidity, dimensions, sp. vol. and tensile properties were detd. by special app. and the results were illustrated by curves. The treatment of the subject was largely mathematical. L. W. RIGGS

Adhesiveness of rice, corn and wheat starches in comparison with potato starch. E. PAROW, A. STIVNUS AND W. EKHAARD. *Z. Spiritusind.* 51, 23-4 (1928).—Rice starch prepd. by the alkali process and slightly alkaline showed decreasing Saare values with longer periods of heating. Neutralized rice starch gave values 3-4 times as great, which increased with the heating period. Rice starch prepd. without alkali gave intermediate values which did not change with heating. The values for corn starch were generally higher and increased with the heating period. Wheat starch values were between those of corn and rice. Potato starch values averaged lower than the cereal starches and tended to decrease as the heating period was prolonged. A. S.

The manufacture of corn starch, utilization of the residue and recovery of corn oil. I. O. K. A. KRIZKOVSKY. *Chem.-Ztg.* 52, 425-8 (1928).—Each state of the manufacture is described as it is carried out in Germany. A. L. HENNE

The vegetable gums—valuation of the commercial products. S. R. TROTMAN. *Chem. Trade J.* 82, 500-1, 525-7, 601-2 (1928).—True gums are classed as: (1) those consisting principally of arabin such as gum acacia, gum arabic, gum senegal and Indian gum; (2) those contg. cerasin and arabin such as the gum from the cherry, plum, almond or peach tree; and (3) gums consisting largely of bassorin such as gum tragacanth. Characteristics of arabin, cerasin and bassorin are noted and specific tests are described for the purity and the valuation for adhesive purposes of gum arabic. Other vegetable products giving colloidal solns. but not contg. arabin, cerasin or bassorin are often designated as gums. Examples are: Irish moss, Iceland moss, agar, algin and pectins. Means of prepn. and tests are given for gum tragacanth. The sources and properties of agar-agar and means of sepg. it from fruit products are noted, and Irish moss, Iceland moss and algin and alginic products, are briefly discussed. Four distinct forms of pectin exist, viz., protopectin, pectin, pectinic acid and pectic acid. Jellifying properties of pectin, extn. from raw materials and various analytical methods are discussed. W. H. BOYNTON

JAGT, H. A. C. VAN DER. **Tabellen ten gebruike in het scheikundig laboratorium van suikerscholen, beetwortelen, rietsuikerfabrieken.** 2nd ed., revised and enlarged. Dordrecht: G van Herwynen. 77 pp. Fl. 1.90.

McNAIR, JAMES B.. **Sugar and Sugar-making.** Chicago: Field Mus. 34 pp. Paper, 50 cents.

Sugar Manual. London: Cifra, Ltd. 2s. 6d., net.

Cold-swelling starch. JULIUS KANTOROWICZ (to William H. Fain). U. S. 1,677,348, July 17. In order to prevent formation of lumps when cold-swelling starch is added to water, the latter is added to a mixt. of the starch with a substance such as Na₃PO₄, alum, borax or MgSO₄ which retards the swelling.

Cold-swelling starch. EUGENE WULKAN (to Harberland Mfg. Co.). U. S. 1,677,314, July 17. A mass of starch is heated to a temp. (suitably about 100-110°) at which cold-swelling starch would be formed in the presence of water, and a reacting liquid such as water is introduced in small individual drops or particles, into the starch

mass, so that individual paste balls are formed, and the latter are then dried. A jacketed kettle provided with an agitator is suitable for the process.

Starch sizing. AUGUSTE BODIN and JEAN EFFRONT. U. S. 1,677,615, July 17. A neutral starch is subjected to the action of starch-liquefying enzymes such as described in U. S. 1,227,525 (C. A. 11, 2263) and the moisture content of the materials during this treatment is controlled so that the product will contain no more moisture than an air-dried product.

Sizing from starch. AUGUSTE BODIN and JEAN EFFRONT. U. S. 1,677,614, July 17. In prep. a sizing for textile material, starch material is directly subjected to the action of a starch-liquefying bacterial enzyme such as that described in U. S. pat. 1,227,525 (C. A. 11, 2263) until at least part of the starch has been liquefied and the action is then stopped, e. g., by heat or acid.

29—LEATHER AND GLUE

ALLEN ROGERS

Leather industry challenges chemical engineering. HAROLD J. PAYNE. Am. Leather Producers, Inc. *Chem. Met. Eng.* 35, 425-7 (1928).—Some of the chemical problems of leather manuf. are briefly presented. E. H.

Application of science to beamhouse operation. GEO. D. McLAUGHLIN. Cincinnati Univ. *J. Am. Leather Chem. Assoc.* 23, 336-44 (1928).—An address. H. B. M.

Further studies on the chemistry of liming. GEO. D. McLAUGHLIN, JOHN H. HIGHBERGER and E. KENNETH MOORE. Cincinnati Univ. *J. Am. Leather Chem. Assoc.* 23, 318-36 (1928); cf. C. A. 21, 3139.—It is shown that amines are formed in skin during curing, during soaking and to a slight extent during liming. Amines accumulate in lime liquors, being carried in from the soaks. Amine formation increases rapidly with temp. above 20°. Nine typical lime liquors contained from 0.0013 to 0.0024% volatile amine as CH_3NH_2 , $\text{C}_2\text{H}_5\text{NH}_2$, and other diamines have more marked unhairing properties than have monamines. Increasing temp. decreases the unhairing action of amines. Pretreatment of skin with satd. $\text{Ca}(\text{OH})_2$ alone decreased the subsequent effect of the amine. When skin is placed in a soln. contg. CH_3NH_2 (1 part skin to 4 parts soln.), the concn. of amine decreases to about 80% of its initial value in 24 hr. and is thereafter const. The combination of skin with $\text{Ca}(\text{OH})_2$ is accelerated by the presence of amine. It is suggested that this is due to activation of the carboxyl groups of the protein. H. B. MERRILL.

Re-use of salt in the curing of animal skins. GEO. D. McLAUGHLIN, IRVIN H. BLANK and GEO. E. ROCKWELL. Cincinnati Univ. *J. Am. Leather Chem. Assoc.* 23, 300-18 (1928).—NaCl once used for curing skins is heavily contaminated with bacteria, blood and other impurities. The re-use of salt increases the initial bacterial count of fresh steer hide by only 1-3%, but the bacteria introduced have a higher salt tolerance, and show proteolytic activity at higher NaCl concns. than do bacteria normally present in skin or present on fresh salt. The bacterial count of steer hide cured with old NaCl decreases slower than that of hide cured with fresh salt. H. B. M.

Hide damage and its prevention. A. GANSSEK. *Gerber* 54, 97-9 et seq. (1928); cf. C. A. 21, 1205.—The principal types of mech. damage are enumerated and illustrated, and methods for their prevention are discussed. H. B. MERRILL.

Synthetic tannins. M. HORI and H. KOMORI. *Repts. Imp. Ind. Research Inst. Osaka (Japan)* 8, No. 3, 1-38 (1927).—Synthetic tannins were prepd. by condensing sulfonic acids of $\text{MeC}_6\text{H}_4\text{OH}$, PhOH , C_{10}H_7 , $\text{C}_{10}\text{H}_7\text{OH}$ or $\text{C}_6\text{H}_4(\text{OH})\text{CO}_2\text{H}$ with HCHO , AcH , paraldehyde or BzH . Various factors in the synthesis and the efficiency of the products in tanning hide were studied. NAO UVEI.

The leaf of *Grewia polygama* and its tannin content. ALICE M. COVERLID. *Proc. Roy. Soc. Vict.* 39, 149-53 (1927), *Australian Sci. Abstracts* 7, 2. H. G.

Chrome tanning. VI. Properties and behavior of chromium sulfate solutions after different pretreatments. E. STIASNY and O. GRIMM. *Collegium* 1928, 49-71; cf. C. A. 22, 696.—A study similar to that on CrCl_3 solns. was made of the combined effect of aging, heat and acid on basic Cr sulfate solns. The changes in p_{H} which were found can be explained by hydrolysis, formation or breaking up of ol. compds., neutral salt effect or change of acid radicals into or out of the chromium complex. The sulfate differs from the chloride in that oxygen bridges do not form, the neutral salt effect is appreciable and the sulfate tends to enter complexes. The pptn. no. was influenced both by the p_{H} and the size of the chrome-complex mols. **VII. Sulfato-chromic sulfate, its behavior on hydrolysis and its tanning action.** E. STIASNY

AND D. BALANYI. *Ibid* 72-97.—Sulfate in the Cr complex (*i. e.*, SO_4 not existing as SO_4^{--} ion) and p_H were detd. in normal and basic $\text{Cr}_2(\text{SO}_4)_3$ solns. after various periods of aging. Ionized SO_4 was detd. by a modification of the benzidine method and SO_4 in the complex by the pyridine method of Gustavson. Sulfato-chromic sulfate is less hydrolyzed and therefore less acid than the hexaquoichromic sulfate (I). On boiling a soln. of I the soln. becomes more acid because a basic sulfato salt contg. ol compds. is formed. On aging the reverse process occurs, but if the boiled soln. is made basic at once the reversal is hindered. On aging or making I basic, SO_4 radicals enter the Cr complex. The Cr complex absorbed by hide powder was richer in SO_4 than the liquor, showing that the compds. richer in SO_4 have greater tanning action. Tanning requires the simultaneous presence of OH groups in the ol form and not in the ol form.

I. D. CLARKE

The fat absorption capacity of chrome leather as concerns sulfonated and unsulfonated fats. E. MEZEY. *Collegium* 1928, 209-13.—The absorption by chrome leather of sulfonated neatsfoot and train oils mixed with the unsulfonated oil or with mineral oil was studied. The greater the proportion of unsulfonated fat the greater was the absorption unless too little sulfonated oil was present to emulsify the unsulfonated oil. In the latter case little fat was taken up.

I. D. CLARKE

The variation in complex bound sulfate in chrome alum liquors. WILHELM SCHINDLER AND KARL KLANFER. *Collegium* 1928, 97-107.—Ionized SO_4^{--} was pptd. cold with BaCl_2 , filtered off and discarded. Then SO_4 held in the complex was detd. as BaSO_4 after boiling the filtrate with HCl. SO_4 held in the complex slowly decreased on aging boiled green Cr alum solns., it was decreased but not entirely replaced by addition of soda, it was entirely removed by $\text{K}_2\text{C}_2\text{O}_4$, and it is decreased greatly during tanning.

I. D. CLARKE

Artificial leather. HEINRICH WIESENTHAL. *Kunststoffe* 18, 128(1928).—There is described an artificial leather and a process of prepg. it. The base is nitro-cellulose or celluloid. The pure celluloid soln. is placed in an upright or horizontal, closed, 1000-2000-l. kettle adapted for stirring. There is then added as solvent 95% alc. with an admixture of small quantities of MeOH, Me_2CO , formic acid esters, amyl acetate, etc. There is usually prepd. a 20% soln., the celluloid and solvent being intermittently introduced into the kettle. The soln. is filtered through a fine brass sieve into a vacuum app.; it is then allowed to stand and ripen for some time. Mineral colors and castor oil are rubbed in. The resulting compn. contains about 25 parts celluloid, 35 parts castor oil and 40 parts mineral color. The objectionable odor is removed by the addition of oil of birch or other perfume. The machines for forming the product are described. The surface of the material is lacquered, or decorated with colors, the decorating being done in such a way that only the deepest colors are retained. Acetylcellulose and artificial resin may be used for the coloring. Processes have been devised whereby the volatile materials may be recovered.

B. H.

Glue testing. Report of the committee on glue testing of the German association for testing technical products. OTTO GERNGROSS. *Collegium* 1928, 130-43.—The results of tests of 10 glues by 4 labs. are given. The agreement was not always good and the various tests did not always give the same quality rating. A "chrome" glue having a high jelly strength was the poorest by the viscosity and adhesion tests. Further work is planned on chrome glues, on H_2O detn. by dissolving the glue to a gel and drying thin layers, on viscosity at different concns. and on adhesion strength of different glues at the same viscosity.

I. D. C.

Utilization of badan for tanning (IGNATIEV) 25. Some useful matters contained in forest trees in Japan [tannins] (MIURA) 22. Physiologic role of the pyrocatechol tannins (MICHEL-DURAND) 11D. Cellulose ester composition [artificial leather] (U. S. pat. 1,676,612) 23.

KOSTIN, N.: Die physikalisch-chemischen Grundlagen der Lederfabrikation in elementarer Darstellung. Vom Verf. bis zur Neuzeit erg. deutsche Ausg. Übers. von Leonid Keigueloukis u. Rudolf Schunck. Leipzig: Paul Schulze Verl. 128 pp. M. 8.

Drying leather. V. G. WALSH. *Brit.* 280,770, March 7, 1927. Leather is dried from the flesh side only while the grain side is covered to prevent evapn. The grain side may be preliminarily treated with a gelatin soln. to ppt. any excess of tanning reagent and the leather then may be stacked with alternate layers of anhyd. Na_2SO_4 spread on the flesh side. Sand may be mixed with the Na_2SO_4 .

Waterproofing leather. HENRY V. DUNHAM (to Van Tassel Co.). U. S. 1,677,435, July 17. Molten paraffin at a temp. of about 150° has incorporated with it about 5-50% of rubber to form a uniform smooth mixt. which if cooled to room temp. is a firm waxy solid. Leather is impregnated with this mixt. while hot, without use of volatile solvents.

Tanning compositions. RÖHM & HAAS, A.-G. Brit. 280,509, Nov. 13, 1926. Emulsions for use in tanning are made by treating oils and fats with freshly pptd. metal hydroxides such as $\text{Al}(\text{OH})_3$ and water. Urea also may be added and assists in dyeing.

Celluloid sheets superficially coated with embedded particles of granulated leather. MILTON H. COOK (to H. N. Cook Belting Co.). U. S. 1,677,125, July 17. A material is specified which is suitable for coating belt pulleys.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

Seasonal variations in the composition of the latex of *Hevea brasiliensis*. NORMAN RAE. *Analyst* 53, 330-4 (1928).—Monthly analyses show that the N, K and P_2O_5 contents reach a max. in Feb., decrease slowly till May, increase to July and then decrease to August. Since the leaf fall coincides with the decrease in March and the maturing of the seeds with the drop in July, it seems possible that latex is a food reserve to be used when the leaf and seed growths are most active. W. T. H.

Comments on a thesis (structure of rubber). J. DUGUÉ. *Rev. gén. caoutchouc* 1928, No. 41, 7-11, cf. *C. A.* 22, 2682.—Only when the properties of rubber are explained in terms of subatomic phenomena, the application of which is illustrated, will it be possible to obtain knowledge of rubber which can be applied systematically to the solution of technical problems. C. C. DAVIS

Plasticity determinations in crude rubber. V. Influence of different factors on the changes in plasticity when keeping the rubber. OTTO DE VRIES. Rubberproefstation Nederlandsch Indië. *Arch. Rubbercultuur* 12, 243-56 (1928) (In English 257-67); cf. *C. A.* 20, 124. A study of the varying compn. of latex and the different methods used in prepg. rubber failed to show that variations in the plasticity of the com. product can be explained by these factors (cf. *C. A.* 22, 2077). The plasticity of raw rubber therefore changes when the latter is kept, so a study was made of the influence of individual factors on these progressive changes in plasticity. The latter plasticity values were detd. when the rubber was new and after 1-2 yrs. When rubber contains below the normal proportion of serum substances, its plasticity increases more on keeping than does that of rubber with a normal quantity of serum substances. The greater the diln. of the latex when coagulated, the greater is the increase in plasticity of the resulting rubber on keeping. This may be a result of the extrn. of serum substances by the water. Since rubber which contains all the serum substances becomes harder when kept, and that which contains a deficiency of serum substances becomes softer, there must be an intermediate proportion of serum substances where the plasticity remains practically unchanged while the rubber is kept. This proportion of serum substances is within the range of that normally present in com. plantation rubber (cf. *C. A.* 22, 2077). The changes in plasticity on keeping are little influenced by the age of the trees from which the rubber was obtained, not even rubber from very young trees changing in any noteworthy manner. Neither does the nature nor the proportion of acid used for coagulation influence these changes in plasticity. Likewise mech. treatment (rolling, milling, sheeting, etc., under different conditions), heating during the drying operation and smoking fail to influence the plasticity in any definite way. On the other hand when a large dose of AcONa is added to the latex, the rubber becomes very weak on keeping, and finely cut, unwashed matured coagulum also becomes very weak in contrast to crepe from matured coagulum which becomes harder to about the same extent as does ordinary crepe. No definite influence on the plasticity on keeping could be attributed to coagulation by heating, whereas coagulation by EtOH tends to cause the rubber to become gradually softer. The plasticity of crepe from ammoniated latex changes in about the same way as that of crepe prepd. under the same conditions from fresh latex. Likewise films from ammoniated latex evapd. in the air become very hard on keeping, in the same way as films from fresh evapd. latex.

C. C. DAVIS

Cooling rubber mills. FRED. GROVE-PALMER. *Rubber Age* (London) 9, 141 (1928).

C. C. DAVIS

Rubber vulcanization accelerators in ultra-violet light from the Hanau analytical quartz lamp. RUDOLF DITMAR AND WILHELM DIETSCH. *Chem.-Ztg.* **52**, 388-9 (1928); cf. *C. A.* **22**, 2291; Kirchhof, *C. A.* **22**, 2291.—Exposure of various accelerators to filtered ultra-violet light showed that most of them are readily distinguishable by their characteristic fluorescence. When they are mixed in pale crepe without any other ingredient, the fluorescent colors of the mixts. are characteristic enough in some cases to distinguish the accelerators. Even when other ingredients, such as S, ZnO, MgO, PbO, etc., are present, it is possible in some cases to distinguish a characteristic fluorescence, though with several ingredients present, the fluorescent effect varies with the different combinations, and only by knowing the compn. of the mixt. does the particular fluorescence have any significance. C. C. DAVIS

Reclaimed rubber compounding. A review of progress made along lines of correct vulcanizing, aging and reinforcement in reclaimed rubber compounds. D. F. CRANOR. *India Rubber & Tire Rev.* **27**, No. 11, 30, 33-4 (1927); cf. *C. A.* **22**, 185 —A crit. review of recent scientific and technical research. Emphasis is laid on the fact that reclaimed rubber may be of inferior quality *per se*, and yet may give disproportionately good results when used as a component in rubber mixts (cf. Winkelmann, *C. A.* **21**, 511). The discussion deals particularly with papers by Vogt (*C. A.* **22**, 1058) and Bierer and Davis (*C. A.* **20**, 2092). C. C. DAVIS

Effect of various carbons in rubber. ELLWOOD B. SPEAR AND ROBERT L. MOORE. *Rubber Age* (London) **9**, 123-5 (1928); cf. *C. A.* **20**, 2095 —C blacks may for convenience be grouped in 4 classes, according to the properties imparted to rubber, the effects being relative only: (1) those which impart great stiffness, high tensile strength and moderate ultimate elongation (channel or gas blacks), (2) those which impart great stiffness, moderate tensile strength and low ultimate elongation (lamp blacks); (3) those which impart little stiffness, moderate tensile strength and moderate ultimate elongation (e. g., thermatomic C), and (4) those which impart little stiffness, high tensile strength and very high ultimate elongation (these blacks are in an exptl. stage, cf. *C. A.* **20**, 2095). Data are presented to illustrate the properties of cured mixts. contg. the different types of C blacks. The radical differences between blacks of classes (1) and (2) on the one hand and of (3) and (4) on the other are especially emphasized. Some C blacks retard the rate of vulcanization, whereas others (class (4)) have a pronounced accelerating action. These effects vary in turn with the type of rubber and with the particular accelerator. C blacks of class (4) are unique in that with certain accelerators, notably diphenylguanidine, and in certain proportions, e. g., 14 parts of C black per 100 parts of rubber by vol., they give mixts. with an ultimate elongation as great as, or even greater than, the basal mixts. contg. no C black. This lends support to the plastic film theory of Wilson applied by Spear to rubber-C black mixts. (cf. *C. A.* **18**, 1064). The ability to add high proportions of C blacks of classes (3) and (4) to rubber renders them particularly serviceable in formulating rubber mixts. resistant to heating. C. C. DAVIS

HAUSER, E. A.: **The Colloid Chemistry of the Rubber Industry.** London: Oxford Univ. Press, Humphrey Milford. 53 pp. 4s. 6d.

Coagulating latex. R. KOEPP & Co. Brit. 280,639, Aug. 18, 1926. A soln. of Na biformate is used as a coagulant, with or without other coagulants.

Compositions comprising rubber and fibrous material. WILLIAM G. O'BRIEN (to Goodyear Tire & Rubber Co.). U. S. 1,676,798, July 10. Rubber is pptd. on fibrous material and liquid from a suspension of the coated fibers is passed through a screen of sufficiently small mesh to retain the fibers and the latter are then treated with a rubber precipitating agent such as alc. which is passed through the screen.

Belt or rubber and rubberized fabric reinforced with twisted cords. AUSTIN A. TRISHER (to Goodyear Tire & Rubber Co.). U. S. 1,676,845, July 10.

Sheet material containing rubber and fiber. REED P. ROSE (to General Rubber Co.). U. S. 1,675,959, July 3. A material suitable for various purposes is formed by mixing a suspension of beaten fibers and an aq. dispersion comprising rubber and protective agent having a negative charge, in an alk. medium, such as a Na resinate soln. and then acidifying the mixt. to reverse the charge on the protective agent and effect deposition of the rubber on the fiber, and forming the material into sheets.

Rubber sheet material with fibrous backing. TON J. MELL (to B. F. Goodrich Co.). U. S. 1,677,284, July 17. Material suitable for use as a floor covering is formed of a rubber sheet with a backing comprising wool felt or other suitable fibrous material

consolidated with bituminous material or other binder which will absorb a rubber solvent such as gasoline without swelling.

Sheet rubber reinforced with wire netting. BERNARD A. RUHLING. U. S. 1,677,372, July 17. Sheets are described which are suitable for use in making automobile bodies, etc.

Apparatus and method for making rubber tubes. JOHN A. FLEISCHLI (to Cupples Co.). U. S. 1,676,776, July 10.

Coating metal with rubber. ALLAN B. MERRILL (to B. F. Goodrich Co.). U. S. 1,677,360, July 17. In making composite sheets, the metal is coated with a tough heat-plastic isomer of rubber such as that formed by heating rubber with phenolsulfonic acid, and a S-contg. rubber compn. is superposed on the coated metal with an intervening layer of material such as a rubber compn. or balata or gutta percha which will inhibit migration of S to the metal, the assembled material is subjected to vulcanization.

Rubber composition for golf-ball centers. PAUL S. SHOAFF (to Goodyear Tire & Rubber Co.). U. S. 1,676,841, July 10. A mixt. of balata resin and scrap vulcanized rubber is heated to reduce it to a gel-like consistency, PbO or other weighting material and S are added, and the product is vulcanized.

Apparatus for vulcanizing rubber articles. CLIFFORD H. OAKLEY. U. S. 1,677,200, July 17.

Apparatus for continuous vulcanizing of rubber heels, etc., under pressure. CLIFFORD H. OAKLEY. U. S. 1,677,201, July 17.

Vulcanizing rubber. ALBERT C. BURRAGE, JR. U. S. 1,677,169, July 17. Di-phenyl-*o*-tolylguanidine or other tri-substituted guanidine contg. phenyl and tolyl substitution radicals is used as an accelerator. Cf. C. A. 22, 2856.

Vulcanizing rubber. RALPH V. HEUSER. U. S. 1,677,235, July 17. *o*-Tolyl-di-*p*-tolylguanidine or other suitable substituted guanidine contg. an aryl group in each of the amino positions and a *p*-substituted aryl group in the imino position is used as an accelerator.

Vulcanizing rubber. BRITISH DYESTUFFS CORPORATION, LTD., C. J. T. CRONSHAW and W. J. S. NAUNTON. Brit. 280,661, Sept. 3, 1926. Rubber is given good aging properties by use of a condensation product of equal proportions of α - and β -naphthylamine with AcH formed in the presence of an acid such as HCl. About 15% of this condensation product may be added to rubber compns. before vulcanizing.

Vulcanizing rubber. LORIN B. SEBRELL (to Goodyear Tire & Rubber Co.). U. S. 1,676,838, July 10. The product of crotonaldehyde, acetaldehyde and aniline or other suitable reaction product of an unsatd. aldehyde, a satd. aldehyde and an amine is used as an accelerator.

CHEMICAL ABSTRACTS

Vol. 22.

SEPTEMBER 20, 1928

No. 18

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

Apparatus in the chemical industry. M. ARGANT. *Science ind.* 12, 43-89(1928).—An illustrated review of chem. app. and plant equipment. R. D. B.

A new watch glass. C. E. IRON. *Chemist-Analyst* 17, No. 3, 18-20(1928).—Four projections are made on the under surface of an ordinary watch glass so that the greater part of the lower surface does not touch the beaker when the watch glass is placed upon it. In this way, it is not necessary to use a glass triangle or glass hooks to raise the watch glass from the beaker when it is desired to accomplish the evapn. of liquid in the beaker. W. T. H.

Hand spectroscope. F. LOWE. *Rev. chim. ind.* 37, 194-6(1928).—The app. described permits the use of test tubes and can also be used to obtain photographs of spectra. P. THOMASSET

Distance thermometer. SCHULZE-MANITIUS. *Warme & Kälte Tech.* 28, 190(1923).—In thermometers in which the reading is carried to a distance by a Hg thread, errors due to expansion of the thread are avoided by providing another similar parallel thread, arranged to act on the dial in the opposite direction. ERNEST W. THIELE

A micro-Saybolt-type viscometer. STUART M. ROGERS AND LINDEN R. ADKINS. Vacuum Oil Co. *Ind. Eng. Chem.* 20, 742(1928).—The app. is an all-metal viscometer, with proportions similar to those of the Saybolt. It operates with as little as 8.5-cc. sample. T. S. CARSWELL

Carbon-resistor furnaces for laboratory use. H. C. KREMERS AND L. F. YNTEMA. Illinois Univ. *Ind. Eng. Chem.* 20, 770-1(1928).—A C-resistor furnace is made by mounting 2 aluminum tubes concentrically on a graphite bar. The space between the tubes is packed with granular C. An Fe collar, the pressure on which is variable, makes contact with the C. A temp. of 1200° may be reached. T. S. CARSWELL

Maintaining the efficiency of evaporators, cooling and condensation coils. S. SCHUTZ. *Wochschr. Brauw.* 45, 244-8(1928).—The common theories of the rusting of iron and its prevention by the use of different protective coatings are discussed. A paint contg. Cr has been found to be very effective against rusting. A. SCHULTZ

Number of plates in fractionating columns. W. L. McCABE. *Ind. Eng. Chem.* 20, 873(1928).—The method of Keyes, Soukup and Nichols (*C. A.* 22, 1875) for calcg. the no. of plates in a fractionating column may cause an error when a low reflux ratio is used, because as the reflux ratio is increased, the vol. of vapor per unit product and the necessary column cross section increase, although the height of the column decreases. T. S. CARSWELL

Number of plates in fractionating columns. D. B. KEYES. *Ind. Eng. Chem.* 20, 873.—Reply to McCabe (preceding abstract) stating that the difference is not great from a practical standpoint. T. S. CARSWELL

An improvised photomicrographic apparatus. CHAS. N. SHAW. *Chemist-Analyst* 17, No. 3, 16-7(1928).—In order to do some photomicrographic work without any of the standard app. available, an outfit was prepd. by mounting an ordinary Kodak camera directly over the eye-piece of the microscope. A complete description of this improvised outfit is given, a picture of the same and a photomicrograph of CuSO₄ crystals magnified about 200 times. W. T. H.

Apparatus for the micro-determination of dissolved oxygen. THOMAS G. THOMPSON AND ROBERT C. MILLER. Univ. of Washington. *Ind. Eng. Chem.* 20, 774(1928).—An all-glass-app. is described in detail, which requires as a sample from 5 to 10 cc. T. S. CARSWELL

Simple apparatus for use in colorimetric titration. EDWIN B. POWERS. University Tennessee. *Ecology* 9, 364(1928).—The app. consists of a 250-cc. Erlenmeyer flask, to the neck of which is sealed a test tube, and to the bottom of which is sealed a neck adapted to take a no. 10 stopper. The liquid being titrated is compared with color

standards while in the test tube portion of the app., and titrations may be carried out under gas pressure. T. S. C.

A continuous extractor. DOUGLAS HENVILLE. *Analyst* 53, 380-2(1928).—The app. was designed for the rapid extn. of as much as 50 g. of material. It is somewhat similar to the Soxhlet extractor but has the following advantages: Neither thimbles nor filter paper packets are necessary; the substance is always immersed in solvent; the "pressure" is directly on the solvent which is directly in contact with the material and the extg. liquid is always in motion; there is a continuous and rapid flow of solvent; if the app. is allowed to stand overnight, the substance remains constantly immersed and the extractor is started again as soon as a little condensate drops down; as soon as the solvent is circulating easily only very little excess solvent is necessary; the contents of the extractor are always visible. W. T. H.

New apparatus for extraction at high temperature. ST. REINER. *Chem.-Ztg.* 52, 529(1928).—This app. is suitable for Soxhlet extns. using inflammable solvents. The only novel feature is the replacement of a multiple place water bath by an elec. heating table capable of accommodating several extn. app. at one time. A. L. H.

Evils of the common cocks for liquid fuels. BRUNO MÜLLER. *Apparatebau* 40, 161(1928).—The Werner cock is recommended. J. H. MOORE

A valve for use in flowing gases. E. BLECHSCHMIDT. *Physik. Z.* 29, 441(1928).—This valve is built of glass very much like a glass stopcock, with no bore but with an opening along the side which gradually closes as the stopcock handle is turned. MALCOLM DOLE

An improved gas generator. V. T. JACKSON. *Florida Univ. Ind. Eng. Chem.* 20, 771(1928).—The app., constructed of bottles, acts much upon the principle of the Kipp generator. T. S. CARSWELL

Insertion of tight-fitting glass tubing into rubber stoppers. T. J. COCHRANE. *Chemist-Analyst* 17, No. 3, 20(1928).—After boring the stopper to the desired size, insert the next larger cork borer into the hole and then shove the glass tubing through the cork borer. Now on removing the borer the glass tube will be in place. W. T. H.

The behavior of rubber-plated apparatus toward organic solvents. A. BRESSER. *Kunststoffe* 18, 125-7, 160-2(1928); cf. *C. A.* 22, 335, 545.—Rubber-plated metals were tested by exposing them to the action of various org. solvents, including isobutyl alc., propyl alc., AcOBu, butyl alc., AcOMe, Me Et ketone, acetone, dichlorohydrin, triacetin, Et₂CO₃, etc. In most instances the coating on the samples became soft and useless. BONIFANT HAMILTON

The development of pipe-line construction. ANON. *Apparatebau* 40, 157-9(1928).—A special flange for high-pressure lines, and a special form of expansion bend are described. J. H. MOORE

Benzine and alcohol recovery equipment. R. W. MÜLLER. *Kautschuk* 1928, 136-7.—An illustrated description of the Sulzer process. C. C. DAVIS

Lead and articles manufactured from it (BRENTHEL) 9.

Filters. JEAN É. A. THILL. *Fr.* 633,092, Apr. 22, 1927. A filter of large capacity is described in which the liquid to be filtered passes through holes in the floor of a tank and is directed by tongues on to inclined filter cloths or gratings arranged as an endless band by passing under and over rollers at the bottom and top of a tank arranged underneath.

Air filter. EDWARD R. HEWITT and ALFRED F. MASURY (to International Motor Co.). U. S. 1,678,044, July 24.

Filter for liquids. VICTOR R. HEFTLER. *Fr.* 632,323, Apr. 7, 1927. A filter for liquids, specially for motor fuels, comprises a series of narrow disks with holes to form canals parallel to the axis of the pile, some of the disks having their peripheries cut away to form a communication between the canals and the exterior of the pile.

Rotary filter for treating coal fines or other materials. ILLINGWORTH CARBONIZATION CO., LTD., and S. R. ILLINGWORTH. *Brit.* 281,390, Sept. 1, 1926.

Filter for lubricating oils, etc. AC SPARK PLUG CO. *Brit.* 281,124, Jan. 24, 1927.

Filter (for edge filtration) for treating lubricating oil, etc. FREDERICK D. HERBERT, WALDO L. KRAEMER and JOSEPH E. GARABRANT (to Metal Edge Filter Corporation). U. S. 1,677,892, July 24.

Apparatus for separating dust from gases. NAAMLOOZE VENNOOTSCHAP MACHINE-RIJEN-APPARATEN FABRIEKEN. *Fr.* 633,268, Apr. 23, 1927. In a dust separator for

gases of the type in which V-shaped channels are placed in the path of the gas with the apex opposed to the current of gas, the angle between the walls of the channels is between 50° and 70° , while the width of the walls is less than 10 mm. and the distance between the channels is one row less than 5 mm.

Centrifugal device for separating dust from air, etc. E. DODSON. Brit. 281,088, Nov. 23, 1926.

Centrifugal apparatus for removing suspended solids from gases. J. THOMPSON (DUDLEY), LTD., AND R. D. WEST. Brit. 281,033, Sept. 10, 1926.

Distilling apparatus. ELIE LIANDIER. Fr. 632,904, Apr. 15, 1927. An app. is described for the distn. of fruit or other solid or pasty substances, in which the perforated plates of the distg. column are in two parts capable of being dropped automatically or by hand into a vertical plane.

Distilling apparatus. SEMET-SOLVAY COMPANY. Fr. 633,201, Apr. 6, 1927. A distg. app. is described which can be used in any distn. system but is particularly for distg. the light oils from the oil used for washing the gas from the destructive distn. of coal.

Distilling columns. ALFRED M. J. SORREL. Fr. 632,450, Apr. 8, 1927. The distg. columns are inclined and arranged so that the bubbling zone on one plate is not beneath the bubbling zone on the plate above.

Improvements in heating-baths. SOC. ANON. ANCIENS ÉTABLISSEMENTS FARGE. Fr. 632,859, Apr. 15, 1927.

Thermometer for indicating the temperature of oil circulating in automobile engines, etc. ARTHUR HOLMES (to Holmes Automobile Co.). U. S. 1,678,389, July 24, 1927.

Pyrometer. VICTORIN C. LOMBARD and JOANNY LOMBARD. Fr. 632,162, Apr. 5, 1927. Colored-glass screens of different thicknesses or prisms are movably mounted between an objective and an eyepiece. The objective is turned toward the source of heat to be measured and the screens are moved till complete extinction of light is obtained, the temp. being deduced from the position reached.

Ultramicroscopes. CHARLES SPIERER. Fr. 632,996, Apr. 20, 1927. An app. is described for illuminating objects for their ultramicroscopic observation by which the light rays reach the object from two different sides.

Apparatus for sublimation suitable for use in analytical work. FRANK A. PEARL. U. S. 1,678,442, July 24.

Air or gas purifier. PIERRE AMET. Fr. 632,551, July 29, 1926. An app. for filtering air or gas specially for engines is described.

Gas and air control and heating system, etc., for regenerative gas-fired furnaces of the reversible open-hearth type. W. SCHUCANY. Brit. 281,002, Aug. 23, 1926.

Apparatus for drying solids and gases. BAECHLER, KISER ET CIE. Brit. 281,664, Dec. 4, 1926. An app. is specified comprising a series of superposed truncated cones and fixed or rotating plates within a vertical cylinder through which the materials treated pass.

Treatment (involving vaporization of magnesium) for obtaining a high vacuum in vacuum tubes. S. LOEWI. Brit. 280,908, Nov. 16, 1926.

Valve for controlling the flow of gas through purifiers, condensers, etc. R. DEMPSTER & SONS, LTD., AND H. LUMB. Brit. 281,001, Aug. 23, 1926. Structural features.

Apparatus for storing radioactive liquids or other liquids containing gases. E. LEVOUX. Brit. 281,228, Nov. 29, 1926.

Vacuum tubes. JEAN B. J. M. ABADIE. Fr. 633,439, Aug. 26, 1926. To maintain a const. pressure in a vacuum tube through which a current is passing a salt is decomposed at the cathode in a manner just necessary to re-feed the tube.

X-ray tubes. N. V. PHILIPS' GLOBILAMPENFABRIEKEN. Fr. 633,598, Apr. 29, 1927.

Electrical treatments for degasifying radio tubes. FREDERICK S. MCCULLOUGH. U. S. 1,677,900, July 24.

Röntgen shield. RUDOLF MANNL. Fr. 633,597, Apr. 29, 1927. The protecting partitions of a Röntgen shield, directed radially toward a common center, are divided into sep. small plates.

Solutions for use in light-transmitting heat screens. C. S. MCNAIR. Brit. 281,066, Oct. 28, 1926. A soln. of alum and a Cu salt, to which Fe or Co salts and dyes also may be added, is used for filling glazed cells for use with optical projection app. or the like. Various structural features are described.

Apparatus for drying industrial products. SOC. IND. BRIQUETTERIE ET CERAMIQUE. Fr. 632,557, Jul. 30, 1926.

Device for delivering measured quantities of dyes or other materials in granular

form. I. G. FARBENIND. A.-G. Brit. 281,645, Dec. 1, 1926. A funnel is provided with spring blades and a slide which serve as measuring devices.

Centrifugal chargers. GABRIEL CLERMONT and ANDRÉ H. NARBONNE. Fr. 632,431, Mar. 14, 1927. The blades on the rotating wheel of centrifugal chargers, for instance, for charging a furnace with coal, are at different angles to the surface of the wheel to cause the coal to spread.

Apparatus for the automatic control of a reduced pressure in a vessel. EZECHIEL WEINTRAUB ET SOC. ALSACIENNE CONSTRUCTIONS MÉCANIQUES. Fr. 633,402, Aug. 17, 1926.

Mill for grinding paints, etc. R. J. DOREY. Brit. 281,062, Oct. 23, 1926.

Colloid mill (with rollers rotating in opposite directions). W. H. WHATMOUGH. Brit. 280,973, May 29, 1926.

Electric system for preventing corrosion of boilers, water heaters, etc. A. GOMEZ. Brit. 281,244, Nov. 26, 1926.

Cleaning textile-material boilers or other high-pressure boiling apparatus. GUSTAV ULLMANN. U. S. 1,678,089, July 24. At the same time that the boiler is blown off a cool liquid diluent such as water is introduced for diluting and cooling the soln. and sludge which are blown off from the boiler. App. is described.

Apparatus for cleaning or scouring tin plates. H. S. THOMAS and W. R. DAVIES. Brit. 281,007, May 24, 1927.

Apparatus for cleaning, scouring and polishing tin plates with bran, etc. R. THOMAS & CO., LTD., and R. A. JONES. Brit. 281,063, Oct. 25, 1926.

Apparatus for testing abrasion resistance of various materials. FRANK A. FAHRENWALD. U. S. 1,678,110, July 24.

Apparatus for regulating the outflow or output of liquids in accord with pressure or temperature conditions, etc. SOC. ANON. SOLEX. Brit. 280,879, Nov. 20, 1926.

Agitator (of the injector type) for mixing oil with purifying chemicals. JOHN W. KINCADE. U. S. 1,678,225, July 24.

Heat-exchange apparatus for cooling oil or other liquids. JAMES MOORE (to Buhmah Oil Co., Ltd.). U. S. 1,678,070, July 24.

Resistance viscometer with associated devices for actuating indicating or concentration-regulating apparatus. ZEILSTOLFFABRIK WALTHER and R. HAAS. Brit. 280,876, Nov. 20, 1926.

Viscometer. GEORGES L. WILLAINE. Fr. 632,339, Apr. 7, 1927. A viscometer is described which depends on the correlation between the viscosity of a liquid and the coeff. of transmission of heat to the liquid. A vessel dipping into the liquid is heated and the difference in temp. of the vessel and the liquid gives the viscosity.

Apparatus for extracting volatile products. AM. HYDROCARBON COMPANY, INC. Fr. 632,716, Apr. 13, 1927. An app. for extg. volatile products from solids comprises an annular vessel, the walls of which rotate and carry blades, the interior wall being cylindrical and the exterior a truncated cone.

Rubber tip for hydrometer syringes. MELVIN S. LOWER (to Sun Rubber Co.). U. S. 1,678,600, July 24. Structural features.

Perforating glass. G. GANZ & CO. (to B. Erber). Brit. 281,648, Dec. 1, 1926. A brass wire which may be first coated with graphite and then electroplated with Cu is sealed into glass and afterward withdrawn to leave a perforation.

Photomechanical screens. F. HAUSLEITER. Brit. 281,137, Feb. 15, 1927. A glass screen is provided with a metal frame around its edge which is applied directly to the glass, e. g., by metal spraying or galvanic plating.

Apparatus for testing tensile strength of various materials. FRANK A. VALENTINE and DAVID C. SCOTT (to Henry L. Scott Co.). U. S. 1,678,369, July 24.

Pulp forming and molding apparatus. ORANGE J. SALISBURY. U. S. 1,677,905, July 24.

Electric condensers. DUBILIER CONDENSER CO. (1925), LTD. Fr. 632,529, Apr. 9, 1927. The insulating bands of elec. condensers are made of rubberized fabric not vulcanized till after the completion of the condenser.

Cathode for thermionic valves. M.-O. VALVE CO., LTD., and M. THOMPSON. Brit. 281,060, Oct. 15, 1926. Cathodes such as those of Pt or W are heated in the vapor of an alk. earth metal such as Ba to form a deposit of the latter on the filament.

Thermionic cathodes for vacuum tubes. RADIOTECHNIQUE. Brit. 281,262, Nov. 26, 1926. Cathodes are formed with a core of W or other suitable refractory metal and an adherent sheath of insulating material such as MgO, BaO, SrO or CaO on which is mounted a helical wire or other suitable form of an electron-emitting material such as thoriated W. The sheath may be formed by heating a wire in MgO; its

m. p. should be between that of the core and the electron-emission temp. of the surrounding helix or the like.

Thermostat. JOHN A. SPENCER (to Spencer Thermostat Co.). U. S. 1,678,407, July 24.

Thermostats. FREDERICK W. MILLER. Fr. 632,938, Apr. 16, 1927. Bi-metal plates for thermostats are made by covering a plate of the metal of higher m. p. with a flux contg. the other metal finely divided, and heating to the m. p. of the second metal.

Thermostatic control system for heating apparatus of buildings. CHARLES L. FORTIER (to Johnson Service Co.). U. S. 1,678,213, July 24.

Electric-recording or thermostatic alarm or temperature-indicating apparatus. REPUBLIC FLOW METERS CO. (to Electroflo Meters Co., Ltd.). Brit. 281,341, Nov. 29, 1926.

Thermostatic electric switch. NICHOLAS J. LUTTRELL. U. S. 1,678,401, July 24.

Thermostatic cut-out for gas valves. RICHARD H. SHADRICK (to Andrew E. Carlsen). U. S. 1,678,169, July 24.

2—GENERAL AND PHYSICAL CHEMISTRY

GEORGE L. CLARK AND J. H. REEDY

The Institute of Chemistry and the American Chemical Society. S. W. PARR. Univ. of Ill. *Ind. Eng. Chem., News Ed.* 6, No 15, 1-2(1928).—Address delivered on the occasion of the opening of the A. C. S. Institute at Evanston, Ill., July 23, 1928.

Influence of chemistry on civilization. JAMES C. IRVINE. Univ. of St. Andrews Scotland. *Ind. Eng. Chem.* 20, 884-8(1928).
E. J. C.

Mongolian distillation apparatus. E. HUBER. *Chem. App.* 15, 145-7(1928).—Historical.
E. H.

Ernst Beckmann (1853-1923). G. LOCKEMANN. *Ber.* 61A, 87-130(1928).—Biography with portrait and bibliography.
J. H. MOORE

Ignác Mościcki, President of the Polish Republic, as technologist. JAROSLAV MILBAUER. *Chem. obzor.* 3, 1-3(1928).—A biography, with portrait, and a short description of his work.
E. H.

Count Rumford—scientist and philanthropist. LYMAN C. NEWELL. *Science* 68, 67-73(1928).
JAR. KUCERA

Color. E. W. PIERCE. *Proc. Am. Assocn. Textile Chem. Colorists* 1928, 200-2; *Am. Dyestuff Rept.* 17, 472-4.—The phenomena of color are discussed from the physicists point of view.
L. W. RIGGS

The atomic weight of cesium. THEODORE W. RICHARDS AND MARCEL FRANÇON. Harvard Univ. *J. Am. Chem. Soc.* 50, 2162-6(1928).—An analysis of CsCl, prepd. by the recrystn. of Cs alums, by comparison with Ag confirmed the at. wt. of Cs to be 132.81.
G. L. CLARK

The structure of atoms as a periodic property and its relation to valence and ion formation. A. A. NOYES AND A. O. BECKMAN. *Chem. Reviews* 5, 85-107(1928); cf. *C. A.* 22, 536-7.—This article presents a compilation of values, derived from recent spectroscopic studies, of the energies attending the removal of the sep. electrons from the atoms and ions of the first thirty elements. With the aid of these values and data as to quantum states, a periodic chart has been prepd. showing graphically the number, the quantum states, and the energies of removal of the electrons in the outer shells of these atoms and ions. These at. structures are discussed in relation to the periods and groups of the periodic system of the elements. The structures are also discussed in detail in relation to the formation of ions in crystals or solns. by the sep. elements, and in relation to the best defined valences which they exhibit. The first eight elements of the third period exhibit max. positive valences that correspond to a reactivity of the electrons outside of the completed $3s$ or $3p$ subshells. All of them beyond Sc form bivalent compounds, which indicates that the $3d$ subshell is an exceptionally stable configuration. The other irregular valences exhibited by these elements are not related in any apparent way to the structure of their atoms.
G. L. CLARK

The helix chemica. B. K. EMERSON. *Chem. Reviews* 5, 215-29(1928).—The original helix chemica of 1911 is a helical arrangement of the elements, the coils increasing in size and number according to the simple geometrical series, $2^{-\infty}$, 2^{-1} , 2^0 , 2^1 , etc., the interspaces increasing by the arithmetical series 1, 2, 3, 4, etc. This paper

is to show that the addn. of two small coils at the origin of the helix as originally published perfects it and that the full development of the series of the powers of 2 demands this addn. It requires one addnl. element, coronium, before hydrogen but this addn. completes the symmetry of the elemental series. The same symmetry suggests the existence of two new elements, between hydrogen and helium as well as the two, coronium and proto-hydrogen, preceding hydrogen. A novel interpretation is given to the occurrence and arrangement of the elements, as shown by charts, as well as criticisms of the at. and Mosely numbers and of the at. structure by Mosely, Langmuir and Lande. The similarity and differences of the helix chemica as compared with Rydberg's arrangement are thoroughly discussed.

Molecular diameters in gas reactions. RICHARD C. TOLMAN, DON M. YOST, AND ROSCOE G. DICKINSON. *Science* 67, 241(1928). Attention is called to a numerical error in a previous paper (*C. A.* 21, 2207), which, however, does not greatly alter the main conclusions.

The allotropic modifications and solid solutions of phosphorus. I. V. NICOLAEV. *Compt. rend.* 186, 1621-4(1928).—The 4 modifications of P (viz., white, purple, red-violet and black), announced by N. and Ipatieff, have now been sepd. mechanically by the laborious process of picking out, under a binocular microscope, individual crystals of the same color and appearance. The d., ignition temp., and vapor tension at 21° were measured for each modification. The results are correlated in a series of graphs for each of which ds. (from 1.8 to 2.7) are taken as abscissas. N. states the following conclusions: (1) The existence of 4 allotropic modifications of P, forming among themselves a continuous series of solid solus., has been demonstrated. (2) The vague idea of red P is replaced by that of 2 species, viz., purple P and ruby P (ruby by transmitted and slightly violet by reflected light). (3) The violet forms are solid solus. of the black and ruby. (4) The white and purple form a eutectic.

The vapor density and some other properties of formic acid. ALBERT S. COOLIDGE. Harvard Univ. *J. Am. Chem. Soc.* 50, 2166-78(1928).—Formic acid probably 99.99% pure was prepd. by vacuum sublimation. The f. p. was 8.26° and the d. 1.2456 at 0° and 1.2206 at 20°. The vapor d. was measured by the method of transferring known quantities of acid to containers of known vol. and observing the pressure developed at a series of temps., between 10° and 156°. A correction for wall adsorption was detd. and applied. The results can be satisfactorily interpreted upon the assumption that the vapor is an ideal mixt. of 2 gases, having single and double mols., resp., each of which deviates from the perfect gas laws in the same way as would a unimol. vapor of similar mol. wt.

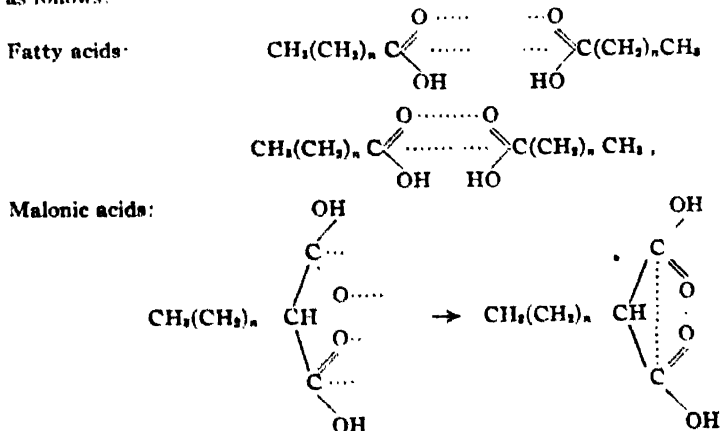

Molecular and atomic volumes. XVIII. The volume of ammonia in crystallized ammonium salts. WILHELM BILTZ AND GUNTHER BALZ. *Z. anorg. allgem. Chem.* 170, 327-41(1928).—The mol. vol. of NH₃ is detd. by measuring the vol. increase produced in monobasic acids when NH₄ salts are formed. In iodic, sulfamic, *p*-aminobenzoic, *β*-naphthalenesulfonic and *p*-aminobenzenesulfonic acids, the mol. vol. obtained for NH₃ is between 19 and 21, but with 1,4-naphthylaminesulfonic acid the mol. vol. of NH₃ in the salt is 28. In the NH₄ salts of the monobasic fatty acids, mol. vols. of 18, 18 and 19 are obtained for NH₃ in the formate, acetate and propionate, but in the butyrate, valerate and capronate, the mol. vol. of NH₃ is 28. In the case of dibasic acids, the introduction of the first NH₂ group results in a normal increase of vol. of about 18, but in the introduction of the 2nd NH₂ group a much smaller increase in vol. occurs, corresponding to a mol. vol. for NH₃ of only 11 in the case of (NH₄)₂SO₄ and 14 in the case of (NH₄)₂SeO₄. In the dicarboxylic acids, the mol. vol. of NH₃ varies around 17, for both the 1st and 2nd NH₂ group, until the higher acids are reached, when it increases, the mol. vol. of the 2nd NH₂ group being 21 in the salt contg. 9 C atoms and 28 in the salt contg. 10 C atoms. In the case of (COOH)₂, the mol. vol. of the 1st NH₃ is 21 and the 2nd 9.8. Density is given for various NH₄ salts of monobasic, dibasic and dicarboxylic acids.

Molecular and atomic volumes. XIX. The densities of uranium, tungsten, and molybdenum chlorides. WILHELM BILTZ AND CURT FENDLUS. *Z. anorg. allgem. Chem.* 172, 385-94(1928); cf. preceding abstract.—The difficulties in the prepn. of each of the chlorides are noted. In some cases the amt. of impurity was detd. and the d. extrapolated. The pycnometer detns. were accurate to several tenths of a percent. The following ds. were found at 25°: UCl₄ 4.854; UCl₃ 5.440; WCl₆ 3.520; WCl₅ 3.875; WCl₄ 4.624; WCl₃ 5.436; MoCl₅ 2.928; MoCl₄ 3.579; MoCl₃ 3.714. For compds. with more than 3 Cl. the at. vol. of Cl varies from 16.0 to 16.5, agreeing with that of free Cl, at. vol. 16.5. For lower chlorides the at. vol. is greater than 16.5, agreeing with the data for In and Ta halides. For the chlorides of W and Mo of mean compn.

the at. vol. is at a min., much the same as in homologous org. series, ammoniates, etc. Compds. in which the halogen at. vol. is the same as the free halogen at. vol. have ionic lattices, those in which the at. vol. is greater have mol. lattices. **XX. Density measurements of iodine chloride.** ERWIN BIRK. *Ibid* 395-402.—The measurements were carried out by an air displacement method, the app. being checked with KCl and *o*-nitrophenol. Values were about 1% low, probably because of gas absorption. Densities found are the following: d_0 β -ICl 3.66, mol. vol. 44.3; d_0 α -ICl 3.85, mol. vol. 42.1; d_2 , liquid ICl 3.10, mol. vol. 52.3. The labile form of ICl changes to the stable with contraction in vol. agreeing with observations on other substances. The mol. vol. of the α -form = $0.81 \times$ mol. vol. of the liquid near the m. p., agreeing with factor for AlI_3 . The d. of ICl_3 was detd. in a pycnometer with liquid chlorine as the fluid. The advantages are that ICl_3 is insol. in dry liquid Cl and that the compd. may be made from its components in the pycnometer; d_{-40° is 3.203, mol. vol. 72.84, corrected to zero point vol. 70.7. The mol. vol. calcd. by addn. is 73.8, hence a contraction occurs in the formation of ICl_3 .

ARTHUR FLEISCHER

An x-ray examination of saturated dicarboxylic acids and of amides of the fatty acid series. EDWARD HENDERSON Univ. of Edinburgh. *Proc. Roy. Soc. Edinburgh* 48, 20(1927-8).—In addn. to the C_6 , C_{10} , C_{12} , C_{14} and C_{16} normal satd. dicarboxylic acids previously investigated with x-rays (*C. A.* 21, 390, 2101), results are now reported for the C_2 to C_8 acids, inclusive. The lower members exhibit a considerable departure from the regularity of structure found for higher homologs. The d. spacing of the odd acids is nearer that of the next lower even acid than the next higher even acid until C_{12} and C_{14} show almost identical values (13.25 and 13.3 A U.). The d_1 and d_2 spacings of the higher odd acids are different from those of the even members, being higher and indicating a longitudinal contraction and lateral expansion. Next, a series of monoalkylmalonic acids were investigated with the following results for the principal spacing d_1 : C_2H_5 .CH(COOH) $_2$ 7.36 A. U.; C_3H_7 .CH(COOH) $_2$ 8.70; C_4H_9 .CH(COOH) $_2$ 9.83; C_7H_{15} .CH(COOH) $_2$ 12.78; $C_{11}H_{23}$.CH(COOH) $_2$ 25.50. The increase per CH_2 group indicates that there is only one mol. between successive reflecting planes. The explanation in terms of partial free valencies of the difference in this respect between the fatty acid series (2 mols. per layer) and the malonic acid series is graphically shown as follows.

The dialkylmalonic acids give similar results. The d_1 spacing of dioctadecylmalonic acid is the same as that of the mono-octadecyl deriv. In lower members, however, the spacing differs. Thus the diethyl is 1.34 A. U. shorter than the monoethyl; the dipropyl 0.80 and the dibutyl 0.63 A. U. shorter than the monoalkyl acids. Results on d_1 for amides are as follows: $CH_3(CH_2)_2$.CONH $_2$ 14.76, $CH_3(CH_2)_3$.CONH $_2$ 19.56, $CH_3(CH_2)_4$.CONH $_2$ 29.56, $CH_3(CH_2)_5$.CONH $_2$ 33.40. These values are similar to those of the acids, again indicating that bimol. layers in the crystals are due to the presence of incompletely satd. terminal groups in the mol. An interesting crit. discussion on the constancy of the increment $\partial d_1 / \partial n$ is given.

G. L. CLARK

Density of fused mixtures of cadmium chloride and potassium chloride. RICHARD LORENZ AND HANS ADLER. *Z. anorg. allgem. Chem.* 172, 372-4(1928).—D. is detd. by using a quartz sinker, weighted with Fe, and attached to a balance pan placed

about 1 m. above the oven contg. the fusion and protected from radiant heat. A linear relation is found between d. and temp. A mixt. comprised of 20 mol. % CdCl_2 and 80 mol. % KCl has a d. of 1.877 at 702° , 1.885 at 685° , 1.903 at 649° , 1.953 at 636° . With 40% CdCl_2 and 60% KCl , d. is 2.308 at 598° , 2.270 at 651° and 2.216 at 720° . With 60% CdCl_2 and 40% KCl , d. is 2.677 at 609° , 2.636 at 651° , 2.593 at 700° and with an 80-20 mixt., d. is 3.17 at 600° , 2.979 at 650° and 2.907 at 700° .

H. STOERTZ

Systematic relationships. XLVI. Measurement of the alternation of chemical relationship in crystallized dicarboxylic acids. WILHELM BILTZ and GÜNTHER BALZ. *Z. anorg. allgem. Chem.* 170, 342-6(1928).—An alternating variation in NH_4 dissoen. pressure with increase in C atoms in dicarboxylic acids is shown. This pressure is higher in the salts with an uneven no. of C atoms than in the salts with an even no. of C atoms on each side. Thus with glutaric acid P_{NH_4} in mm. for the acid NH_4 salt is 37, with adipic acid it is 0, with pimelic acid it is 182, with suberic acid it is 18, with azelaic acid it is 210 and with sebacic acid it is 25. Similar alternation in electrolytic dissoen. between even and uneven C atoms likewise is observed in the dissolved acids. In the NH_4 salts this alternation is observed in the increase in mol. vol. as NH_4 is substituted for H to produce the acid salt, but when the 2nd NH_4 is introduced no alternation in mol. vol. increase occurs. Alternation is also shown in the heat of combustion of dicarboxylic acids.

H. STOERTZ

The crystal form of ψ -yohimbine. T. ITO. *Z. Krist.* 65, 303-5(1927).—Crystals of ψ -yohimbine are holohedral orthorhombic, with axial ratio 1.042:1:1.690. The indices for Na light are α 1.571, β 1.642 and γ 1.655.

B. C. A.

The crystal form of methyl tetrathionoxalate. H. HIMMEL. *Z. Krist.* 65, 496-9(1927).—The *cis*-form is holohedral monoclinic, with $a:b:c = 0.8356:1:1.1684$, $\beta = 124^\circ 32'$; m p. 71.5. The *trans*-form is also monoclinic, with $a:b:c = 0.7919:1:0.6059$, $\beta = 99^\circ 48'$; m p. 101.5.

B. C. A.

The equation of state of a gas. KAMEKICHI SHIBA. *Proc. Phys. Mat. Soc. Japan.* 9, 157-62(1927).—Assuming that the mols. of a gas are similar, perfectly elastic, smooth spheres with cohesion which depends only upon their mutual distance, the following modification of van der Waals' equation has been found: $p + (a/v^2) + c(ab/v^3) = (RT/v)[1 + (b/v) + (5/8)(b^2/v^2)](1)$, in which c is a numerical coeff. detd. by the relation $a'/a = cb$, where a and b are the van der Waals' corrections due to cohesion and to mol. vol., resp. Letting the mass and the diam. of a mol. equal m and σ : $a = (2\pi/3m^2) \int_0^\infty r^2 f(r) e^{-2h \int_r^\infty f(x) dx} dr$ [$h = (N/RT)$]; and $b = 2\pi\sigma^3/3m$. Equation (1) may be reduced to: $p + (a/v^2) + c(ab/v^3) = (RT/v)[1 + (b/v)]$, which may be written as: $(p + \phi(T)/v - (c/2)b)(v - b) = RT$, which is very like Clausius' equation of state. Data calcd. with S.'s equation of state agree approx. with the results of Debye's theory.

J. H. PERRY

The validity of gas equations (of state). IV. W. HERZ. *Z. Elektrochem.* 34, 68-9(1928); cf. *C. A.* 21, 2206.—Tables contg. the satn. pressure and the d. of the satd. vapor for a no. of org. and inorg. compds. are compared. Ratios of the pressure and the d. with different fractions of the abs. crit. temp. (T_c) are given and it is indicated that the ratios are the smallest at the crit. temp.; at $2/3 T_c$ the ratio is equal to 2 to 2.5 and at $1/3 T_c$ the ratio remains about the same. The ratios increase with the crit. temp., at first very rapidly, then more slowly, pass through a max. and again decrease.

J. H. PERRY

The relation of liquid properties to orthobaric densities. W. HERZ. *Z. anorg. allgem. Chem.* 172, 414-6(1928); cf. *C. A.* 21, 1399, 2084, 3505.—From H.'s previous work and MacLeod's equation for the relation of surface tension to d., H. deduces 2 equations for the relation of heat of vaporization and for viscosity to the orthobaric d. of a liquid. The equation is shown to hold for nonassociated liquids. A. FLEISCHER

The theory of the liquid state of aggregation. E. N. GAPON. *J. Russ. Phys.-Chem. Soc.* 60, 249-64(1928).—Assuming that internal pressure $P = C\gamma(1 + fT)$ (1), where γ is surface tension and f its temp. coeff., G. substitutes from the b. p. equations $fT_s = 1.40$ and $P_s/\gamma_s = 75.3$ and finds $C = 31$. Equation (1) is now rewritten: $P = 3/\gamma(1 + 2.2\theta)$ (2), where θ denotes reduced temp. P calcd. from (2) for PhCl and PhNMe_2 shows a continuous decrease with the rise in temp. while $P(Mv)^{1/3}$ remains const. Also, for these two liquids $P = 114T_s/(Mv)^{1/3}$ (3), T_s being b. p. in $^\circ\text{K}$. Equation (3) combined with that of Herz (*Chem. Ztg.* 41, 183(1917)) gives $aP(Mv)^{1/3} = 50.0$, which can be extended to consider liquids under external pressure: $\alpha_p (P + p)V_p^{2/3} = \alpha_{p1} (P + p_1)V_p^{2/3} \dots = 50.0$. The relationship holds within 10% for CS_2 and Et_2O . If p is negligible, $P = p/(\alpha_1/\alpha_p - 1)$. Stefan's formulas lead to too

large values of P for associated liquids because exptl. λ is the sum of the heats of evapn. and dissociation. The connection between γ and P explains the variations of the Eötvös-Ramsay-Shields const., high values corresponding to P of 200–500 atm. Equation (3) is transformed into $\beta T_i/(\alpha(Mv)^{1/2}) = \text{const.} (= 1.28 \text{ at } 20^\circ)$. The av. exptl. value for 65 liquids is 1.20; the equation was applied to associated liquids by substituting xM for M , and x was calcd. for 13 org. liquids. G. observes that among alcohols and acids the higher homologs are less associated; addnl. OH groups and side chains also decrease x . For Hg, $x = 2.5$ at room temp. The equation $\gamma\beta(2.2 + T_k/T) = 10.6 \times 10^{-3}$ (T_k being crit. temp.) holds within 10% for 24 liquids, the exptl. value of the const. being 9.0×10^{-3} . The equation $\beta = 0.41 f/\gamma$, agrees with the behavior of 11 org. compds.

BASIL C. SOYENKOFF

The internal pressure of pure and mixed liquids. W. WESTWATER, H. W. FRANTZ AND J. H. HILDEBRAND. Univ. of Calif. *Phys. Rev.* 31, 135–44(1928).—Internal pressures were measured on the principle of a const.-vol. thermometer for 8 pure liquids and 12 mixts. of 50 mol. % compn. Values for the former are given at 15° , 20° , 25° and 35° and for the latter at 20° , 25° and 35° . The values of γ in atm. per degree at 20° are as follows: (1) heptane, 8.66; (2) acetone, 11.22; (3) CCl_4 , 11.47; (4) benzene, 12.58; (5) CS_2 , 12.67; (6) $(\text{CH}_2\text{Cl})_2$, 14.17; (7) $(\text{CH}_2\text{Br})_2$, 15.20; (8) CHBr_3 , 15.32. The values of γ for the mixts. at 20° are, designating the components by the foregoing nos. 1–2, 9.27; 1–3, 9.68; 1–4, 9.86; 1–5, 9.84; 1–7, 10.66; 1–8, 10.86; 3–4, 12.19; 4–5, 12.32; 4–6, 12.92; 4–8, 14.05; 2–5, 11.77; 5–7, 13.98. It was found further (1) that γ is a function of the sp. or molal vol. only; (2) that for each pure liquid $v_2 T \gamma$ is a const., a , v being the molal vol. and T the temp. at which the pressure is 1 atm. (a function of molal vol.); (3) that the values for the mixts. are less than additive, less than those calcd. from the equation of Biron, $\gamma = \gamma_1 \gamma_2 / (\gamma_1 N_1 + \gamma_2 N_2)$ where N_1 and N_2 are the mol. fractions of the components, here 0.5; (4) that they are given within 1 or 2% by the relation $a = (a_1 a_2)^{1/2}$ except in some of the mixts. of CS_2 , acetone and $(\text{CH}_2\text{Cl})_2$ —the first of these is in other respects irregular and the last two are polar; and (5) that a still better agreement is given by considering that γv is additive. The compressibility, β , can be calcd. by combining γ with the coeff. of expansion, $\alpha = \beta \gamma$. In most instances, the agreement with the directly detd. values is satisfactory.

BERNARD LEWIS

The determination of the vapor pressures of odoriferous substances. G. TAMMANN AND W. OELSEN. *Z. anorg. allgem. Chem.* 172, 407–13(1928).—The method consists in satg. air with the substance whose v. p. is being detd. and then dilg. the satd. air till the odor can just be detected. At the same time the threshold value is detd. for the persons used to detect the odor. The temp. at which a substance could be detected by odor was also detd. For a given person the variation was 1.7° , for seven persons the deviation from the mean temp. was 1.2° . For camphor at -40° and -18.5° the vapor pressures found were $0.842 \pm 0.133 \times 10^{-3}$ and $7.30 \pm 0.36 \times 10^{-3}$ mm., resp. These values agree with the values found by other methods. The threshold values for 7 persons varied from 6 to 13×10^{-9} g./cc. For butyric acid the v. p. at -78° and -22° were $1.13 \pm 0.20 \times 10^{-6}$ and $3.74 \pm 0.37 \times 10^{-3}$ mm., resp. The threshold values varied from 0.9 to 1.2×10^{-10} .

ARTHUR FLEISCHER

Unimolecular films. SHEPPARD AND KEENAN. *Nature* 121, 982(1928).—The thicknesses of unimol. films are measured as follows: A drop of a soln. of the compd. studied is allowed to spread upon a mercury surface, the film area being developed with talc powder and its area measured with a planimeter. From the area and the concn. of the compd. in the solvent the thickness is calcd. By plotting film thickness against concn. a point is reached where the thickness value becomes independent of concn. These values in A. U. for a few of the compds. studied are as follows: cellulose nitrate, 3 to 5; stearic acid 22 to 24; oleic acid 11.2; elaidic acid 12.2; *n*-caproic acid 13.6. The data are interpreted to agree with the present theories of polymerization and with atom-group orientation theory of colloid micelle formation. G. L. C.

Method for the measurement of interfacial tension of liquid-liquid systems. F. E. BARTELL AND F. L. MILLER. Univ. Michigan. *J. Am. Chem. Soc.* 50, 1961–7(1928).—A method based upon the capillary-tube principle was developed for the detn. of the interfacial tension of liquid-liquid systems, designed especially for systems where one of the liquids was colored. Two somewhat different types of app. were designed. The method is rapid; the app. can be cleaned easily; non-transparent liquids can be used, likewise liquids of any d. The app. can be placed in a H_2O thermostat and kept at a const. temp. while readings are being made. It is not essential that the diam. of the capillary be strictly uniform throughout. Calibration of capillary radius is necessary only for a given point on the capillary tube; also for work of ordinary

accuracy no capillary corrections for meniscus height readings are necessary. Results which have been obtained show a close agreement with what are believed to be the most accurate interfacial-tension data available in the literature. C. J. WESR

Phenomena occurring in the condensation of molecular streams on surfaces. J. D. COCKCROFT. *Proc. Roy. Soc. (London)* A119, 293-312(1928).—The rates of condensation of streams of Cd and Ag vapors at low pressure are studied (1) when the d. of the stream is approx. const. and the condensing surface has a known temp. gradient, (2) when the d. of the stream varies from point to point on a condensing surface of const. temp. and (3) when different materials are used for the condensing surface. A new app for measuring the phenomena under conditions (2) and (3) is described. At densities below a certain crit. value, no deposit is formed. The crit. d. for Cd on Cu varies with temp. in the range -150° to -90° according to the relation $\nu = 4.7 \times 10^{22} e^{-2840/T}$. This is of the form required by Frenkel's theory of adsorption (cf. C. A. 18, 3302). Numerical values for the energy required to remove one member of an at. "doublet" from the surface and for the mean life of the doublets are calcd. The theory also gives the correct relation between the time of appearance of a visible deposit and the stream d. If the latter is at least 4 times as great as ν , the proportion of atoms which re-evap. can be neglected. The value of ν is found to be the same within 1 or 2% for condensing surfaces of Cu and Ag (-137° and -170°), and a similar result is obtained with Cu and glass. When a fresh Ag surface is deposited immediately before condensation of Cd, and when other precautions are taken to remove contamination from the condensing surface, the d. required to form a deposit decreases by a factor of 10. This shows that the true surface forces were probably masked by adsorbed gases. The surface motion of condensed metal atoms required by the F. theory is verified by a photomicrographic method, and by observation of the optical properties of the condensed film. A magnetic field of 10,000 gauss has no effect on the condensation phenomena. F. A. JENKINS

The sorption phenomena and chemical processes. IV. Heterogeneous chemical reactions. S. LIPATOV. *J. Russ. Phys.-Chem. Soc.* 59, 969-80(1927); cf. C. A. 22, 1264.—The chem. reaction between nitroalizarin and $\text{Cu}(\text{OAc})_2$ bears an external resemblance to an adsorption process. Two samples of nitroalizarin were studied with a view to reproducing phenomena considered peculiar to adsorption. The time curve is much flatter in the case of coarse powder. The c_1/c_2 curve is convex toward the c_1 axis due to free AcOH formed, the effect becoming more pronounced on the addn. of more acid. The addn. of 0.5 N Na_2SO_4 straightens out the curve, and so does 0.5 N NaCl in dil. solns.; the extent of adsorption is decreased. The amt. of $\text{Cu}(\text{OAc})_2$ withdrawn is proportional to that of the solid phase. The colloid particles of nitroalizarin being aggregates of minute crystals, the solute probably diffuses among them until it reaches unaggregated units, whereupon chem. reaction begins. The compd. formed slides off the crystal, thus exposing a fresh surface. Although nitroalizarin is more sol. than BaSO_4 , the reaction with $\text{Cu}(\text{OAc})_2$ does not take place in the liquid phase only, since the equil. is not detd. by the final concns. of the reagents in soln. BASIL C. SOYENKOFF

The influence of structure, configuration and the degree of saturation of organic acids on the extent of their adsorption from solutions on charcoal. E. V. ALEKSEEVSKIĬ. *J. Russ. Phys.-Chem. Soc.* 59, 1033-42(1927).—An activated sample of Merck's animal charcoal was shaken with an acid soln. for 10 min., allowed to stand for a day and filtered, aliquot portions being titrated. $\text{MeCH}:\text{CHCOOH}$ is adsorbed more than PrCOOH , possibly because of the greater soly. of the latter (de Tzaguirre). $\text{Me}_2\text{CHCO}_2\text{H}$ is less adsorbed than PrCO_2H although it is also much less sol. in H_2O . A. therefore concludes that a straight-chain acid occupies less surface in an adsorbed layer. Fumaric acid is adsorbed from H_2O and MeOH to a greater extent than maleic, again possibly because of the difference in soly. In EtOH , however, the more sol. maleic acid is the one better adsorbed. The less sol. $(\text{CH}_3\text{CO}_2\text{H})_2$ is adsorbed from H_2O to a greater extent than maleic acid; the latter is preferentially adsorbed from EtOH , although it is also the more sol. one. A. concludes that a double bond decreases the adsorbability from H_2O and increases that from EtOH . BASIL C. SOYENKOFF

Adsorption phenomena in solutions. X. The relation between adsorption and the p_H value of solutions. SOPHIE PEVSNER. *Z. physik. Chem.* 133, 122-8(1928).—The effect of variable p_H values of buffer solns. on the adsorption of weak electrolytes or nonelectrolytes has been studied: (1) (with phosphate buffer) glucose, HCHO , arsenic acid, $\text{C}_6\text{H}_5\text{OH}$, $(\text{CH}_3)_2\text{CO}$, HCN and H_3BO_3 and (2) (with acetate buffer), $\text{CO}(\text{NH}_2)_2$ and $\text{C}_6\text{H}_5\text{NH}_2$. Graphs of p_H (abscissa) vs. amts. adsorbed (ordinate) show either 2 min. or 2 max. at p_H values lying between 5 and 7. J. H. PERRY

Adsorption phenomena in solutions. XIII. Adsorption from mixed electrolytes. MICHAEL DUBININ. *Z. physik. Chem.* 135, 24–35 (1928).—Adsorption from solns. of mixed electrolytes and non-electrolytes by wood and sugar charcoals was measured. The electrolyte pairs were $\text{HCl} + \text{HNO}_3$; $\text{HCl} + \text{H}_2\text{C}_2\text{O}_4$; $\text{HBr} + \text{HNO}_3$; $\text{HCl} + (\text{CH}_3)_2\text{CO}$; $\text{CH}_3\text{COOH} + (\text{CH}_3)_2\text{CO}$; $\text{NaCl} + \text{NaNO}_3$; $\text{NaCl} + \text{NaNO}_2$; $\text{NaCl} + \text{Ba}(\text{NO}_3)_2$; $\text{BaCl}_2 + \text{NaNO}_3$; $\text{BaCl}_2 + \text{Ba}(\text{NO}_3)_2$. The ratio $(b - y)/x$, where b = the amt. of one constituent adsorbed, from a soln. of that constituent only, y = the amt. of the same constituent adsorbed in the presence of a second constituent and x the amt. of second constituent alone adsorbed, was found to be const. over a range of 5-fold variation in concn. of one of the constituents. From this equation there can be calcd. a value representing the ability of one component to displace another from the adsorbent.

R. L. DODGE

The dehydrogenation theory of Wieland. K. TANAKA Dairen Hospital. *J. Oriental Med.* 4, 4 (1925); *Chem. Zentr.* 1927, I, 225.—In the reaction of methylene blue, EtOH and Pd, the H does not come from the EtOH as assumed by W., but is previously adsorbed on the Pd. Pd first treated with O is inactive. HCN arrests the oxidation by O but not the reduction of methylene blue. The dehydrogenation theory is not sufficient to explain the facts.

C. C. DAVIS

The primary action of chromic acid on animal fiber. M. A. IL'INSKIĬ AND D. I. KODNER. *J. Russ. Phys.-Chem. Soc.* 60, 193–207 (1928).—Samples of wool were placed in 0.05 N H_2SO_4 contg. 0.09–0.49 g. $\text{K}_2\text{Cr}_2\text{O}_7$ at 17–19° for 0.25–6 hrs. and solns. titrated for CrO_3 . After 30 min. 50% of $\text{H}_2\text{Cr}_2\text{O}_7$ is absorbed, and equil. is reached before 6 hrs. The amt. absorbed is greater in the presence of H_2SO_4 than without it, both approaching the limit of 10.8% with increasing concn. Further increase is very slow and probably due to the hydrolyzing and oxidizing action of $\text{K}_2\text{Cr}_2\text{O}_7$. Temp. rise does not affect the absorption of $\text{K}_2\text{Cr}_2\text{O}_7$ but accelerates the oxidation of wool as a secondary reaction. For a given concn. of $\text{H}_2\text{Cr}_2\text{O}_7$ absorption increases with the amt. of H_2SO_4 toward a sp. limit beyond which the addn. of H_2SO_4 does not influence the reaction between $\text{H}_2\text{Cr}_2\text{O}_7$ and wool. $\text{H}_2\text{Cr}_2\text{O}_7$ displaces quant. H_2SO_4 and HCl from wool except after long interaction between the latter and H_2SO_4 , in which case the amts. liberated are slightly below the theoretical. The difference probably remains in combination with the weaker NH_2 groups. The chromates formed in silk and wool are very slowly and slightly washed out with water. Wool probably forms a compd. $[\text{R}(\text{CO}_2\text{H})\text{NH}_2]_2\text{H}_2\text{Cr}_2\text{O}_7$. Treatment of woollen fabrics with $\text{K}_2\text{Cr}_2\text{O}_7$ in the cold followed by dyeing, instead of the reverse, results in heat economy. The Cr-wool complexes remain stable and insol. after reduction with NaHSO_3 preliminary to the use of easily oxidizable dyes.

BASIL C. SOYENKOFF

Chemical fogs. H. O. ASKEW. *Trans. Proc. New Zealand Inst.* 59, 165–207 (1928); cf. *C. A.* 21, 2829.—Clouds produced by phys. means have been studied in connection with the condensation of H_2O vapor on ions formed from Ra or by thermal or elec. methods. The chief chem. fogs studied have been those formed by O_3 and reducing agents; NH_3 and HCl; org. bases and HCl; H_2SO_4 , HCl and HNO_3 with H_2O ; Ra and ultra-violet light; during electrolysis; "smoke fogs," etc. The ease with which suspended matter may be removed from a gas varies greatly according to the substance in suspension; thus certain materials are removed by concd. H_2SO_4 when not by H_2O . With SO_3 clouds formed by rapid cooling are more difficult to remove than those formed by slower cooling, probably because of the smaller size of the former. In chem. warfare it has been found that there is a min. efficiency for a filter at a certain crit. size of particle. With COCl_2 led through alcoholic NaOH, fogs occurred only when hydrolysis had split off HCl. Similarly, with POCl_3 and HCl fogs were formed only when free HCl occurred in the gas and when free alkali was present. If EtOH, Me_2CO , Et₂O, AmOH were present also, the fogs are much more dense. Expts. with COCl_2 , HCl and HBr were conducted, the purification, concn., partial pressure, etc., of the gas being carefully regulated, and the sizes of the orifices and their depths of immersion in various liquids, sizes of the bubbles, rate of flow, intensity of the fog, its absorptive qualities, the quantity of alkali present, the influence of gelatin, gum arabic, iso-AmOH, saponin, $\text{C}_6\text{H}_5(\text{OH})_3$, sucrose, safranin, methylene blue, Congo red, suspensions like kaolin, aquadag and clay, and of alc., pyridine, etc., studied. By the Stokes-Cunningham equation radii of fog particles were calcd. from their rates of fall, giving values near 9×10^{-4} cm. for fogs from aq., 7.6% and 35% alc., pyridine and HBr solns., the radius remaining const. at all stages of the neutralization, but increasing during the time of settling. With fogs from solns. of dyestuffs, colloids, suspensions, etc., the radii were smaller (approx. 0.7 to 2.6×10^{-4} cm.). It appeared that the original size of the particles is of the same order as for fogs from other reactions

viz., 5×10^{-5} cm., but these are unstable and increase rapidly to perhaps 2×10^{-4} cm. Apparently an equil. state is reached by the particles, since vapor pressure and concn. of acid in the droplets remain const. and independent of the conditions of formation, no matter whether HCl or HBr is used. Electroscopic examn. for charges on the particles gave no deviations of more than 2 or 3% from the "natural value;" the amt. of charge is, therefore, zero or too small to be measured by this means. Quant. data on concns. show that there is a logarithmic relation between alkali concn. and fog formation in aq. solns.; with small quantities of colloids and suspensions this is also true. If the alkali concn. is kept const. and the concn. of added substance is varied, each substance has its own specific effect. That surface tension is not the controlling factor so far as fog formation is concerned is shown by the fact that, although AmOH causes a great reduction in the surface tension, it is not very active as regards fog formation. If a gas contg. HCl vapor be passed through aq. NH_3 , fogs are formed in all cases, because even in very dil. solns. NH_3 has an appreciable partial pressure. If the vapor from even concd. NH_3 be passed through fairly strong HCl solns., no fog is formed until the partial pressure of the chlorides rises above the infinitesimally small value in more dil. solns., *i. e.*, only above about 18% acid, and even here the partial pressure of the acid vapor is merely a fraction of a mm. For any pair of jets studied the ratios of the radii and times of contact are practically the same; hence the amts. of fogs obtained in simple alkali solns. do not vary a great deal, a result in harmony with the two-film theory of gas absorption. All considerations lead to the conclusion that the alkali film is the cause of the decrease in the absorption of an acid by the solvent. The alk. film, with its adsorbed material, appears to act as a membrane which is more permeable to water vapor than to other gases or ions. Much more work is necessary before condensation and the stability of particles can be explained satisfactorily.

W. C. EBAUGH

The adsorption of excess ions by positive and negative silver halide, and thiocyanate silver sols. A. LOTTERMOSER AND W. PETERSEN. *Z. physik. Chem.* 133, 69-121 (1928).—The amt. of adsorption increases with decreasing soly. of the salt. The adsorption of Br^- and I^- ions by negative AgBr and AgI sols is greater than the adsorption of Ag^+ ions on the corresponding positive sols. The negative AgCNS sol has a much smaller adsorption for CNS^- ions than the negative AgBr sol possesses for Br^- ions, although they are only slightly more sol.

J. H. PERRY

Preparation of gold sol. N. KEULEMANS. *Pharm. Weekblad* 65, 647 (1928).—In a 1-l. flask which has been thoroughly cleansed with aqua regia and freshly distd. H_2O , dissolve 0.05 g. AuCl_3 in 500 cc. freshly distd. H_2O , add 0.12 g. K_2CO_3 and heat to boiling. Remove the flame, add 0.125 g. glucose and shake vigorously until a bright purple-red color develops. The colloidal soln. is preserved in amber bottles that have been thoroughly cleansed. Au sol has been prescribed for internal treatment of certain skin diseases.

A. W. DOX

Colloidal gold solution. The preparation of gold solutions and their titration with permanent hydrogen-ion concentration standards. VINCENT CHRISTINA AND CLARA S. GREEN. *J. Lab. Clin. Med.* 13, 678-81 (1928).—A slight modification of Zsigmondy's method of prepn. of colloidal Au is described, wherein cond. water, instead of triply distd. water, is used, in addn. to an increased amt. of alkali. The titration of the soln. is accomplished with phenol red as an indicator, and the p_{H} is detd. with permanent inorg. standards.

ETHEL W. WICKWIRE

Gelatin as an emulsifying agent. I. I. ZHUKOV AND I. N. BUSHMAKIN. *J. Russ. Phys.-Chem. Soc.* 59, 1061-9 (1927).—Gelatin of isoelec. pt. 5.27 was used. The surface tension of solns., measured with a Donnan pipet, is a function of p_{H} . It reaches a min. at the isoelec. pt. When 2 parts of C_6H_6 by vol. are shaken with 1 part gelatin soln. an unstable emulsion of the soln. in C_6H_6 results; the phases are reversed when 2 parts of the soln. are shaken with 1 part of C_6H_6 . A stable emulsion of C_6H_6 in gelatin soln. results from equal vols.; its viscosity increases on addn. of C_6H_6 until a virtual solid is obtained contg. 95 parts C_6H_6 . The reversal of phases does not take place. The max. stability of C_6H_6 emulsions in gelatin solns. coincides with the isoelec. pt., *i. e.*, min. surface tension and viscosity. Two min. points on the stability curve correspond to viscosity max. at p_{H} 2.5 and 9.5. Non-hydrated and undissocd. gelatin mols. thus serve best as emulsifying agents.

BASIL C. SOYENKOFF

The science of colloids and its applications. HENRI BRAIDY. *Ind. chimique* 15, 294-6 (1928).—The first article of a review on colloids. This article deals with the meaning of the word colloid and also with their structure.

P. THOMASSET

Combined water of colloids. JULES AMAR. *Compt. rend.* 186, 1147-9 (1928).—The H_2O of ovalbumin consists in 2 parts, an indifferent part and a combined part.

For 3 cc. of dry ovalbumin there are 8 cc. combined H_2O and 9 cc. indifferent H_2O . Likewise it has been found that gelatin, cellulose and kaolin also contain a small amt. of H_2O seemingly united.

E. G. VANDENBOSCHE

Coagulation through agitation and vibration. TADEUSZ KUCZYNSKI. *Przemysł Chemiczny* 9, 84-93(1925); *Chem. Zentr.* 1926, II, 2883-4.—The effect of vibration on the settling of fine Berlin blue ppts. was investigated. Under the influence of vibration, Berlin blue ppts. settle much more rapidly than when allowed to stand undisturbed, a difference which is attributed to a more rapid coagulation of the sols. Likewise the clarification and crystn. of a Ca ferricyanide soln. is accelerated by vibration. A high-speed motor mounted on an elastic support was used to obtain the necessary vibration. As a further explanation of the influence of vibration on coagulation, the behavior of dialyzed Fe hydroxide, colloidal Au, etc., was studied. The expts. show that vibration alone does not bring about coagulation, the latter occurring rather at the point of contact with other media.

C. C. DAVIS

Hysteresis in the coagulation and sedimentation of suspensions, emulsions and colloidal solutions. B. II'IN. *Inst. Physics Biophysics, Moscow. Zhurnal expl. biol. med.* 1926, 1-28; *Chem. Zentr.* 1926, II, 3090; cf. C. A. 20, 3606.—By sedimentation or coagulation hysteresis is meant the varying rate of sedimentation, which can be quant. measured, which is observed when suspensions or colloidal sols. treated with a sedimentation agent are allowed to settle after different intervals of time following the addn. of the agent. The phenomenon can be explained by adsorption or other reactions.

C. C. DAVIS

The distribution of hydrogen ions between gelatin and water. I. SHUKOV, S. SICHUKAREV AND I. BUSHMAKIN. *Univ. of Petrograd. J. Russ. Phys.-Chem. Soc.* 58, 639-58(1926); *Chem. Zentr.* 1927, I, 408-9.—A part of the work has already been published (C. A. 19, 1518). The p_H values of gelatin sols. in the presence of H_2SO_4 + Na_2SO_4 , $AcOH$ and HCl were detd. potentiometrically at 30° . At the isoelec. pt. p_H was 5.25. The discrepancies in the data of various investigators probably depend upon the variations in com. gelatins.

C. C. DAVIS

Effect of previous history on the viscosity of gelatin solutions. CLARKE E. DAVIS AND HENRY M. SALISBURY. *Ind. Eng. Chem.* 20, 829-31(1928)—Viscosity measurements over a p_H range from 1 to 9 were made at 40° with 1% sols. of pig-skin and ossein gelatin prepd. by both acid and alkali cooking. Below p_H 4.7, the p_H -viscosity curves of all the samples were similar but the shape of the alk. side of the curve depended on the previous history of the gelatin.

J. J. McNALLY

The cataphoretic migration velocity of large particles in sols and gels. II. H. FREUNDLICH AND H. A. ABRAMSON. *Z. physik. Chem.* 133, 51-68(1928); cf. C. A. 21, 3517.—The cataphoretic migration velocity of large particles is independent of their form, from a study of quartz particles in pure H_2O , in H_2O -sols. of sugar and $NaCl$, and in serum, as well as for glass and kaolin particles in H_2O . Proteins like gelatin, albumin and hemoglobin in very dil. suspensions (10^{-7} g. per l.) decrease the migration of quartz particles in H_2O , while other hydrophyllic colloids (starch, Na oleate) do not do this. At higher protein concns., 10^{-4} g./l. of egg albumin, 10^{-3} g./l. of gelatin, the migration velocity of the quartz particles is independent of the protein concn. The particles then behave exactly as if they are covered completely with proteins, i. e., like protein particles. It is therefore possible that the cataphoresis of proteins is a function of the p_H of the soln. Not all solid surfaces behave like particles of quartz, ZnO , and air bubbles; for example, erythrocytes in serum have about twice the cataphoretic migration velocity of quartz particles, the velocity of which is as large as that of the leucocytes in spite of the large concn. of Fe in the serum. In mixts. of serum with gelatin, which contain so little gelatin that the whole is a soft gel, the erythrocytes migrate twice as rapidly as quartz particles and leucocytes. Particles may migrate through a gel, without any change in the velocity due to the gel structure.

J. H. PERRY

The speed of absorption of sulfur dioxide by magnesium hydroxide. PAUL RIOU AND A. P. BEWARD. *Compt. rend.* 186, 1465-7(1928).— SO_2 is absorbed almost as readily by H_2O as by a soln. of $Mg(OH)_2$; the greater the amt. of solid $Mg(OH)_2$ present the greater the speed of soln.; the speed is decreased with rise in temp. Increasing the amt. of solid $MgSO_4$ present in a soln. of $MgSO_4$ decreases the speed of soln.

E. G. VANDENBOSCHE

What is osmosis? ORTON K. STARK. *Science* 67, 556-7(1928).—The inexact nature of the terms employed in describing osmosis is discussed. "Osmosis, then, can be defined briefly and accurately as diffusion through a membrane, the direction of the major movement being from a region of high concn. to a region of low concn."

of the thing diffusing. Such a definition will apply to all cases of the phenomenon, no matter how complicated."

L. W. RIGGS

Determination of the specific gravity of van't Hoff equilibrium solutions at 83°. F. SEROWY. *Mitt. Kali-Forschungsanstalt* 1921, 53-69; *Chem. Zentr.* 1927, I, 491-2.—Two precisely detd. values of the sp. gr. in the range of the van't Hoff equil. point are used to interpolate and extrapolate and thus obtain the desired sp. gravity. This is possible because the latter is a continuous function of the mol. differences of the analyzed and of the original prepd. solns. (The solns. were prepd. according to the van't Hoff directions and were analyzed after 24 hrs. at 83°.) Almost all of the analyses are in terms of % by wt., mols. per 1000 mols. of water, mol.-% and g. per l.

C. C. DAVIS

Determination of the specific gravity of saturated magnesium chloride solutions between 20° and 100°. QUEISNER. *Mitt. Kali-Forschungsanstalt* 1921, 75-8; *Chem. Zentr.* 1927, I, 558.—From detns. of the d. of satd. $MgCl_2$ solns. at 20, 30, 60 and 80° a continuous curve was constructed. The values for 40, 50, 70, 90 and 100°, which lay slightly above or below the curve, varied from the exptl. values only in the 4th place of decimals or at the most by 1 unit in the 3rd place of decimals. Similarly by plotting the mols. of $MgCl_2$ per 100 mols. of water, calcd. from the analyses, a curve was obtained which conformed to that of the mean satn. nos. of van't Hoff, and which approached the values of Dawson for low temps., but which was at all temps. considerably different from the data of Classen

C. C. DAVIS

The solubility of gases and the coefficient of dilatation by absorption. I. JURO HORIUCHI. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 119 72(1928); [English Ed. 1, 11-7].—The following data refer to gases dissolved in CCl_4 ; the solute, the temp., the soly. (γ), the crit. temp. of the solute and $\ln \gamma P_k$ (P_k = crit. pressure) are given successively: H, 25°, 0.085, 33.2, 0.037; air, 25°, 0.198, 132.5, 0.867; CO_2 , 25°, 2.668, 304.1, 2.289; N_2O , 25°, 4.285, 309.6, 2.487; SO_2 , 25°, 18.51, 430.2, 3.158; SO_2 , 40°, 12.49, 430.2, —. The following data are first the temp., then the soly. of N_2O in C_6H_6 , $ClPh$, CCl_4 , $MeOAc$ and Me_2CO : 1.41° , —, —, —, 9.30; 10°, 4.453, 3.891, 5.26, 8.035, 7.64; 15°, —, 3.636, 4.89, —, —; 20°, —, 3.382, 4.57, —, —; 25°, 3.686, 3.174, 4.285, 6.27, 5.95; 30°, —, 2.981, 4.005, —, —; 35°, —, 2.801, 3.775, —, —; 40°, 3.123, 2.650, 3.565, 4.05, 4.73; 45°, —, 2.520, —, —, —; 50°, —, 2.400, —, —, —; 55°, —, 2.279, —, —, —. The next figures indicate: the solute, the temp., the coeff. of dilatation by absorption, the calcd. soly. and the observed soly.; soly. in Me_2CO : N_2O , 0°, 0.00180, 8.48, 9.08; N_2O , 10°, 0.00189, 5.85, 7.64; N_2O , 25°, 0.00202, 3.75, 5.95; N_2O , 40°, 0.00211, 3.08, 4.73; CO_2 , 10°, 0.00190, 10.3, 9.0; CO_2 , 25°, 0.00199, 6.17, 6.295. Soly. in CCl_4 : N_2O , 10°, 0.002022, 5.28, 5.26; N_2O , 25°, 0.02130, 4.12, 4.57; N_2O , 40°, 0.002176, 3.81, 3.56; CO_2 , 25°, 0.00229, 3.04, 5.668; soly. in C_6H_6 : N_2O , 10°, 0.00206, 3.90, 4.453; N_2O , 25°, 0.00219, 3.07, 3.69; N_2O , 40°, 0.00223, 2.54, 3.12; CO_2 , 0°, 0.00200, 7.84, —; CO_2 , 25°, 0.00219, 3.50, 2.425; H_2 , 0°, 0.00170, 0.0166, 0.048. The following figures indicate the solvent, the solute, the temp., the coeff. of dilatation on absorption, the calcd. and the observed solubilities: $MeOAc$, N_2O , 25°, 0.00202, 4.80, 6.27; $MeOAc$, CO_2 , 25°, 0.00199, 7.31, 6.494; $ClPh$, N_2O , 25°, 0.00203, 3.19, 3.17; $ClPh$, CO_2 , 25°, 0.00201, 5.55, 2.265; $CHCl_3$, CO_2 , 0°, 0.00188, 7.75, 5.0; Et_2O , CO_2 , 0°, 0.00200, 8.94, 7.330; Et_2O , N_2 , 0°, 0.00184, 0.024, 0.1115.

A. L. HENNE

The solubility of chromic anhydride in aqueous sulfuric acid. A. V. RAKOVSKII AND D. N. TARASENKOV. *J. Russ. Phys.-Chem. Soc.* 60, 7-12(1928).— CrO_3 interferes with the detn. of H_2SO_4 as $BaSO_4$; titration with $Ba(OH)_2$ also gives results in error by 7.7%. The acid mixt. is made alk. with $NaOH$ and the excess titrated back in the presence of Congo red. CrO_3 was detd. by the I method. The error rarely reached 0.5%. The soly. of CrO_3 in H_2O was 61.94% at 0°, 60.54% at 100°. The system $CrO_3-H_2SO_4-H_2O$ was studied at 0, 20, 40 and 100°. The soly. curves are continuous, proving the existence of a single solid phase confirmed by Schreinemaker's method of residue. Brownish yellow crystals sep. from satd. soln. of CrO_3 in 90% H_2SO_4 whose compn. is best represented by $CrO_3 \cdot SO_3$, CrO_3 is split off in contact with air of 1.7% relative humidity at room temp.

BASIL C. SOYENKOFF

Solutions of salts in pure acetic acid. I. Preliminary paper. ARTHUR W. DAVIDSON. Univ. of Kansas. *J. Am. Chem. Soc.* 50, 1890-5(1928).—A qual. study is made on the soly. of salts of inorg. bases in $AcOH$ (I). The halides and nitrates were generally more sol. and the sulfates much less so. Double decompn. reactions readily occurred as detd. by the soly. of the salts formed. Na_2CO_3 was the only salt noticeably solvolyzed by I liberating CO_2 ; $CaCO_3$ was not affected. The soly. of $Zn(OAc)_2$ in I was markedly increased by the addn. of 5 mol. percent of $NaOAc$ and the soly. of $Cu(OAc)_2$ was improved by NH_4OAc .

D. H. POWERS

The solubility of potassium bromide in acetone as related to the inter-ionic attraction theory. A. L. ROBINSON. *J. Phys. Chem.* 32, 1089-93 (1928).—An attempt is made to verify the factor $(DT)^{1.5}$ of the Debye and Hückel equation for the activity coefficient of an ion: $\log f_i = -\frac{e^2 N^2 (\pi/R)^{0.5} z_i^2 (\sum c_i z_i^2)^{0.5}}{R(DT)^{1.5}}$ by measuring the soly. of KBr

in acetone and acetone plus other solvents giving both heterionic and homoionic solvents. A plot of $\log S/S_0$ against the square root of the ionic strength is given and explained, along with the exptl. method. The Debye and Hückel theory is closely checked, the failure to check exactly being attributed to traces of water in the acetone.

G. L. CLARK

The formal and real concentration of solutions. M. LEVAT-EZERSKII. *J. Russ. Phys.-Chem. Soc.* 59, 1019-28 (1927).—A review of L.'s previous papers on the osmotic and vapor pressures of solns. An attempt is made to det. the phys. meaning of factor $i = (\Delta t \text{ observed} / \Delta t \text{ calcd.})$, the salts NaNO_3 , AgNO_3 and KNO_3 being chosen because they are presumably not hydrated in soln. Arrhenius' i is calcd. from the data of Kohlrausch (iI) and L.'s $i = N(p/p_1 - 1)/n$, denoted by iII , from the b. p. and f. p. data. These values obtained at different temps. are comparable because p/p_1 changes appreciably with temp. only for more concd. solns. than 3 M. In the case of NaNO_3 , iI decreases and iII increases with the increasing concn.; the only explanation lies in the hydration of undissocd. mols. The iI for AgNO_3 is slightly larger than iII , probably as a result of mol. compd. formation (double etc., mols. of AgNO_3). iI and iII for KNO_3 solns. differ negligibly over the range of 5-28%. L. concludes that neither hydration nor compd. formation takes place. BASIL C. SOYENKOFF

Hydrogen-ion concentration and p_H —an explanation. A. LEE CALDWELL. *J. Am. Pharm. Assoc.* 17, 136-8, 529-34 (1928).—An attempt to explain the relationship between H-ion concn. and p_H . Some of the applications of p_H values to pharmacy are mentioned. Directions for the prepn. of buffer solns and indicator solns. are given. The technic of making the p_H detn. is described. L. E. WARREN

A simple, cheap and rapid method for measuring hydrogen-ion concentration. LEOPOLD POLLAK. *Gerber* 54, 99-100 (1928).—The "Folienkolorimeter" is described. The indicator is adsorbed by a membrane permeable to water. The p_H value of a soln. is estd. from the color assumed by the membrane after immersion for 1 min. The app. is especially adapted to turbid solns. H. B. MERRILL

A prevalent error in the derivation of the freezing-point and boiling-point laws for dilute solutions. A. W. DAVIDSON. *J. Phys. Chem.* 32, 1080-5 (1928).—The prevalent error in the derivation of the freezing- and boiling-point laws, according to the reversible cycle of van't Hoff, of the failure to take into consideration the heat equiv. of the osmotic work is pointed out. No changes occur in either of the final equations, however. The derivations are corrected and a new derivation is presented, following the same scheme, for the approximate form of the freezing-point equation for ideal solns.

G. L. CLARK

The dissociation constants of diphenyl- and di-*o*-tolylguanidine. LUDWIG METZ. *Z. Elektrochem.* 34, 292-4 (1928).—The dissocn. consts. calcd. from cond. measurements of dil. solns. at 18° are 6.09×10^{-5} for diphenyl- and 4.72×10^{-5} for di-*o*-tolylguanidine. J. G. McNALLY

The hydration of ions and molecules. II. Hydration and ionic mobility. E. N. GAPON. *J. Russ. Phys.-Chem. Soc.* 60, 237-48 (1928); cf. *C. A.* 22, 526, 1082.—The following empirical equation holds for 100 org. ions within about 10%: $u\sqrt{n}$, where u is ionic mobility and n the no. of atoms composing the ion. Similarly, for 14 complex ions contg. 1 metallic atom $u\sqrt{n} = 154$ (1). The no. of H_2O mols. in the inner coordination sphere, $m = (n - 1)/3$, obtained from u for Li-Cs, Cl-I, Tl and Ag agrees with the generally accepted values. From (1) it follows that diffusion coeff. of a binary electrolyte $D = 6.907 [1 + 0.0034(t - 18)]/(\sqrt{n_+} + \sqrt{n_-})$. The diffusion equation (cf. *Ukr. Chem. J.* 2, 459, 1926) is used in considering the addn. of a chem. inert component to the soln.; the following deductions agree with the expt. The effect of such addn. on diffusion velocity is independent of the amt. of diffusate, being sp. for the solvent. If the diffusate reacts with the new component, the diffusion is accelerated thereby. Since the velocity of soln. $K = D/\delta_0$, it similarly follows that the change in K on the introduction of a chem. inert component depends not on the nature of the dissolving substance but on that of the solvent. The no. of solvated mols. of the component is expressed in terms of the initial and final K and properties of the solvent and the new component. (K_2/K_0) depends on the change in viscosity resulting from the addn. of a new substance as well as the extent of its solvation. K_1 and D_1 are max.

when 2 components are present in their combining proportions; min. K_1 and D_1 correspond to max. disson.

BASIL C. SOYENKOFF

The influence of the so-called higher terms in the Debye-Hückel theory of solutions of strong electrolytes. T. H. GRONWALL, VICTOR K. LA MER AND KARL SANDVED. *Physik. Z.* 29, 358-93(1928).—The fundamental equation of the Debye-Hückel theory (C. A. 17, 2665) is

$$\frac{1}{r^2} \frac{d}{dr} \left(r^2 \frac{d\psi_i}{dr} \right) = - \frac{4\pi e}{D} \sum_{i=1}^s \frac{N n_i z_i}{V} e^{-\frac{ze\psi_i}{kT}}$$

and with the limiting conditions of $\psi_i = 0$ when $r = \infty$, $\frac{d\psi_i}{dr} = -\frac{ez_i}{D} \frac{1}{a_i^2}$, when $r = a_i$ det. the electrostatic potential ψ_i of an ion of the i th kind. The symbols denote: V = the vol. of soln. which contains n_0 mols. of solvent and n_i mols. of ions of the i th sort ($i = 1, 2, \dots, s$) of valence z_i and apparent diameter a_i cm., D = the dielec. const. of the soln. which may depend on the abs. temp. T and also on the mol. fractions, N = Avogadro's no., k = the Boltzmann const., e = the electronic charge in electrostatic units. For elec. neutrality $\sum_{i=1}^s n_i z_i = 0$. Development of the exponential function according to powers of ψ_i leads to the equation

$$\frac{d}{dr} \left(r^2 \frac{d\psi_i}{dr} \right) - \kappa^2 r^2 \psi_i = \kappa^2 r^2 \Phi(\psi_i) = \kappa^2 r^2 \sum_{\nu=2}^{\infty} \frac{(-1)^{\nu-1}}{\nu} \left(\frac{e}{kT} \right)^{\nu-1} q_\nu \psi_i^\nu$$

where $\kappa^2 = (4\pi N e^2 / kTD) \sum_{i=1}^s (n_i z_i^2 / V)$ and $q_\nu = \sum_{i=1}^s n_i z_i^{\nu+1} / \sum_{i=1}^s n_i z_i^2$. In order to calc. ψ_i Debye and Hückel neglect the higher powers of ψ_i and use the equation $(d/dr)[r^2(d\psi_i/dr)] - \kappa^2 r^2 \psi_i = 0$, from which they obtain $\psi_i = [ez_i/D(1 + \kappa a_i)] / [\epsilon(\kappa a_i - r/r)]$. In this paper an integration method is developed for the calc. of ψ_i from the unabridged fundamental equation. In the case of very small concns. asymptotic expressions are found which result in the conclusion that the limiting law of Debye is not merely the basis of the Debye approximation but is entirely general. Expressions for free energy and activity coeff. are obtained in the form of infinite series in powers of $1/D$. For the case of electrolytes whose positive and negative ions have the same valence the numerical values of the functions occurring in the series up to terms in $1/D^5$ inclusive are given in tabular form. Comparison of the derived formulas with exptl. data shows excellent agreement even in cases of small ionic diam. where the Debye approximation fails to work. Assumptions supplementary to the Debye-Hückel theory, such as the association hypothesis of Bjerrum (C. A. 22, 1263), are superfluous.

EDGAR R. SMITH

Velocity of reaction between two liquid phases. W. FRAENKEL, E. WENGEL AND L. CAHN. Univ. Frankfurt A. M. *Z. anorg. allgem. Chem.* 171, 82-97(1928); cf. C. A. 18, 1774.—F. and W. have studied the reactions occurring when various acid solus. are in contact with many amalgams of Ca, Sr, Ba, Li, Na, K, Be, Mg, Al, Cs, Rb and Zn. Reproducibility of the results was difficult to obtain, since many variable factors were involved. Potential measurements of the reactions were made against a N calomel electrode and were found to be capable of duplication if platinized Pt was used as the other electrode; smooth Pt gave varying results. This work gave indications that the overvoltages of the metals were intimately related to their behaviors. Constancy of the reaction velocity rates is well ascertained in the data given. The rates parallel the potentials of the various metals and are dependent upon the H-ion concn., rate of stirring, vol. and surface area of the amalgams; a linear relationship exists in many cases. F. and C. have examd. the rate of reaction between a bromoform soln. of diazoacetic ester and aq. HNO_3 solns., the N_2 produced by hydrolysis affording a method of measurement. Variation of the concn. of ester over the exptl. range had no effect. Decrease in the concn. of the catalyzing acid lowers the reaction rate while decrease in the speed of stirring has the same effect. Many tables are given. W. E. V.

The reactivity of solid substances. E. KORDS. *Zement* 17, 94-8(1928).—The mobility of atoms and mols. of cryst. solids is shown by metathetical reaction, diffusion, m. p. lowering of mixts. and recrystn. On the abs. scale the temps. of these reactions bear the following relation to the melting temps.—metals = 0.33-0.40, inorg. salts = 0.57 and mol. compds. = 0.9. The more complex the compds., the nearer the m. p. before activity begins. M. p. lowering is greater for high-temp. reactions than lower

ones. Thus CaSiO_3 (m. $1785^\circ\text{K}.$) lowers the m. p. of CaF_2 ($1651^\circ\text{K}.$) about 250° but that of CaCl_2 ($1045^\circ\text{K}.$) only 6° . Many silicate reactions are governed by this reactivity. Quartz plus BaCO_3 reacts, at 700° to 800° , while quartz plus BaCO_3 plus Na_2CO_3 begins to react at 400 – 450° . The speed of reaction of solids only is slower than in the presence of a flux. H. F. K.

The kinetics of chemical reactions, between a solid and a gaseous component, which form complex compounds. A. PREDVODITELEV AND A. WITT. *Z. physik. Chem.* 132, 47–54 (1928).—A microbalance is described by means of which the reaction kinetics of solid CuSO_4 and gaseous NH_3 ($\text{CuSO}_4 + 5\text{NH}_3 = \text{CuSO}_4 \cdot 5\text{NH}_3$) have been measured. This reaction takes place according to the equation: $dc/dt = qp(B - C)/(C_0 - C)$. Where C is the concn. of the ammoniate, p is the pressure, and q , B and C_0 are constns. J. H. PERRY

Carbon dioxide cleavage from acetonedicarboxylic acid. E. O. WING. *J. Phys. Chem.* 32, 961–81 (1928).—This paper is an interpretation of exptl. facts to explain the mechanism of decompn. of acetonedicarboxylic acid. The exptl. evidence may be briefly summarized as follows. The decompn. of acetonedicarboxylic acid is a first-order reaction, the reaction rate being practically independent of the nature of the walls of the reaction flask. Acetone, a product of decompn., has practically no effect on the velocity of decompn. The effect of catalysts dissolved in water, aniline and alcs. on the rate of reaction has been detd., after the reaction rate had been detd. in each of the pure solvents. Observations were made on the effect of HCl salts and colloids on the rate of decompn. in water. The temp. coeffs. for the various alcs., for water and for the various catalysts in alcs. and in water have been calcd. Measurements of the completeness of decompn. in various solvents, with and without catalysts have been made at temps. varying from 0° to 60° . A complete discussion is given of the results and a mechanism has been proposed, postulating the formation of an unstable intermediate compd. of the formula: CH_3COOH

CO Catalyst

CH_3COOH

G. L. CLARK

The velocity of formation of an insoluble anhydride. P. P. BUDNIKOV. *J. Russ. Phys.-Chem. Soc.* 59, 881–9 (1927).—The influence of time and temp. on the formation of insol. CaSO_4 was studied. A sample (0.6 g.) of finely powd. $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ was heated to 140 – 200° for 2–40 hrs. and quickly introduced into a cond. cell contg. 200 cc. H_2O . Cond. measurements at 20° with rapid stirring gave the concn. of sol. CaSO_4 . Insol. CaSO_4 first appears when the hydrate is heated at 140° for over 17 hrs., while after 40 hrs., 16.7% is formed. When the hydrate is heated at 160° , the insol. gypsum appears after 5 hrs. and its content reaches 20.7% after 40 hrs. At 200° the insol. CaSO_4 appears immediately, its content at the end of 40 hrs. being only 15.7% (possibly due to a difference in particle size). At 220° the amt. of the insol. anhydride reaches 22.6% after 40 hrs. Protracted heating is, therefore, detrimental to the mech. properties of gypsum plaster. BASIL C. SOYENKOFF

The velocity of oxidation of alcohols, ethers and esters by potassium permanganate and chromic anhydride under various conditions. B. V. TRONOV AND A. A. LUKANIN. *J. Russ. Phys.-Chem. Soc.* 59, 1157–72 (1927).—To a H_2O soln. of the oxidizing agent (KMnO_4 , $\text{KMnO}_4 + \text{KOH}$, $\text{KMnO}_4 + \text{H}_2\text{SO}_4$, CrO_3 , $\text{CrO}_3 + \text{H}_2\text{SO}_4$) in a thermostat was added an equiv. or a large excess of the alc. or ester. The reactions being assumed to be bimol., the constns. were calcd. The oxidation of EtOH , PrOH and EtCHO by CrO_3 is represented satisfactorily by a second-order equation; Me_2CHOH less so. Consistent values of k were obtained with $\text{CrO}_3 - \text{H}_2\text{SO}_4$ and Me_2CHOH , EtOH and Et_2O . The latter is scarcely oxidized in the absence of H_2SO_4 , while esters are apparently hydrolyzed by CrO_3 soln. Expts. with KMnO_4 gave good values for k except in the case of Me_2CHOH . PrOH reacts more rapidly with CrO_3 , Me_2CHOH with KMnO_4 . KMnO_4 acts about 100 times faster in alk. than in neutral media. The oxidizing capacity of CrO_3 increases in presence of H_2SO_4 in a similar ratio; the reaction goes to completion in acid media, while in neutral soln. only 30% of the available O is utilized. Esters and ethers are oxidized by CrO_3 much more slowly than the corresponding alcohols, the difference being less marked in the case of acid and neutral KMnO_4 , while alk. KMnO_4 acts about equally well. Apparently only alk. KMnO_4 attacks the alkyl radical. BASIL C. SOYENKOFF

The velocity of oxidation of alcohols by chromic anhydride and nitric acid in aqueous solutions. B. V. TRONOV, V. F. UDODOV AND M. I. CHIZHOVA. *J. Russ. Phys.-Chem. Soc.* 59, 1149–56 (1927).—Equiv. amts. of aq. CrO_3 were added to the alcohols at room

temp., the resulting concns. being 0.3 *M*. Samples were titrated at intervals with $\text{Na}_2\text{S}_2\text{O}_3$. In the expts. with HNO_3 , 67 or 39% acid was added to an equiv. of alcohol; samples were titrated with NaOH . Me_3COH is not acted on, EtOH is oxidized more readily than MeOH , esp. by HNO_3 ; susceptibility of the primary alcohols to oxidation increases with the length of chain. The Ph or the $\text{CH}_2\text{:CH}$ group favors oxidation. PhCH_2OH reacts more readily than $\text{CH}_2\text{:CHCH}_2\text{OH}$. Secondary alcohols are more active towards HNO_3 and Br_2 , less active towards CrO_3 , than the primary. B. C. S.

The velocity of oxidation of alcohols by potassium permanganate. B. V. TRQNOV, A. A. LUKANIN AND I. I. PAVLINOV. *J. Russ. Phys.-Chem. Soc.* 59, 1173-97 (1927).—The initial concns. of the alc. and KMnO_4 were 0.03 *M*. Each expt. was carried out at 16, 18, 21 and $24 \pm 0.05^\circ$. Difficultly sol. alcohols (iso-AmOH , $\text{C}_7\text{H}_{15}\text{OH}$, PhCH_2OH , $\text{Me}(\text{CH}_2)_{11}\text{CH}_2\text{OH}$) were shaken before and during the reaction. The oxidation of primary alcs. follows the second-order equation until large amts. of reaction product accumulate. $\text{Me}(\text{CH}_2)_{11}\text{CH}_2\text{OH}$ shows increasing values of the const., probably because its oxidation products are more sol. than the alc. itself. With the secondary alcs., *k* is not a const. $(\text{CH}_3\text{OH})_2$ gives consistent values, $\text{MeCH}(\text{OH})\text{CH}_2\text{OH}$ less so. With glycerol *k* increases as the reaction progresses. Monohydric alcs., except $\text{CH}_2\text{:CHCH}_2\text{OH}$, decrease the valence of Mn ion from 7 to 4, while polyhydric alcs. carry the reduction farther. The following results were obtained in alk. media. The oxidation *k* of MeOH was fairly const. until 10% of the available O was utilized, whereupon it decreased twice, *k* of PrOH decreased to a const. value at 10% O; *k* of $\text{Me}_2\text{CHCH}_2\text{OH}$ decreased to 20% O; Me_2CHOH gave consistent values of *k*. Following are the av. values of *k* in neutral soln. at 21° : MeOH $3.0438, 3.0280 \times 10^{-5}$; EtOH , $3.2261, 3.3371 \times 10^{-5}$; PrOH $2.9213, 3.1867 \times 10^{-5}$; BuOH $4.0975, 4.1332 \times 10^{-5}$; $\text{Me}_2\text{CHCH}_2\text{OH}$ $3.8261, 4.1567 \times 10^{-5}$; iso-AmOH $5.1977, 5.3821 \times 10^{-5}$; $\text{C}_7\text{H}_{15}\text{OH}$ $4.0937, 3.2620 \times 10^{-5}$; $\text{Me}(\text{CH}_2)_{11}\text{CH}_2\text{OH}$ $10.5360, > 3.0000 \times 10^{-5}$; $\text{CH}_2\text{:CHCH}_2\text{OH}$ 5×10^{-5} ; PhCH_2OH $1.7483, 1.5202 \times 10^{-5}$; Me_2CHOH 5.0616×10^{-5} ; MeEtCHOH 8.0430×10^{-5} ; $\text{C}_6\text{H}_5\text{OH}$ $10.66488, 9.3454 \times 10^{-5}$; Me_2COH 0; Me_2EtCOH 9.2759×10^{-5} ; pinacol 2.8912×10^{-5} ; $(\text{CH}_3\text{OH})_2$ $5.3789, 6.1826 \times 10^{-5}$; $\text{MeCH}(\text{OH})\text{CH}_2\text{OH}$ $11.3817, 8.0146 \times 10^{-5}$; glycerol 9.4638×10^{-5} ; erythritol $> 36.3850 \times 10^{-5}$; adonitol $> 4.8585 \times 10^{-5}$; mannitol $> 4.5387 \times 10^{-5}$. In alk. media, (before 5% O) MeOH 2.4×10^{-4} ; PrOH 9.2×10^{-4} ; $\text{Me}_2\text{CHCH}_2\text{OH}$ 1.2×10^{-3} ; Me_2CHOH 1.1×10^{-3} ; Me_2COH 2.5×10^{-3} . Secondary alcs. are oxidized more rapidly than the primary. Lengthening the chain, the introduction of Ph or a double linkage increases the reaction velocity. An OH group in glycols and glycerol is not oxidized faster than in monatomic alcs. BASIL C. SOYENKOFF

The mechanism of the hydrolysis of saccharin and *o*-sulfaminobenzoic acid. KURT TAUFEL, CARL WAGNER AND WILHELM PREISS. *Z. Elektrochem.* 34, 281-91 (1928); cf. C. A. 21, 78.—Saccharin is stable in boiling water but hydrolyzes to *o*-sulfaminobenzoic acid in the presence of acid or alkali. The alk. hydrolysis is bimol., the rate being proportional to the concn. of saccharin and OH ions. The velocity const. at 100° is 0.020 (time in min.). The reaction proceeds no further in neutral or alk. solns., but in acid solns., the *o*-sulfaminobenzoic acid is hydrolyzed to acid NH_4 *o*-sulfohenzoate. The rate of this reaction is independent of the concn. of the catalyst (perchloric acid) and the monomol. const. at 100° is 0.045. The dissoen. consts. of saccharin were found to be 9.86, 8.32, 5.76 and 4.53×10^{-3} at mol. vols. of 100, 200, 400 and 800 l., resp. The second dissoen. const. (NH_2 group) of *o*-sulfaminobenzoic acid is given as 2.1×10^{-2} at room temp. and the second const. of *o*-sulfohenzoic acid as 1.9×10^{-3} . The ionic equilibria of the system are given in a chart. J. G. MCN.

The kinetics of the hydrolysis of diketopiperazine. ARNE ÖLANDER AND HANS V. EKLUND. *Z. physik. Chem.* 134, 381-6 (1928).—The basic dissoen. const. of diketopiperazine in 0.01 *N* NaOH was so small that it could not be measured electrometrically. The acid dissoen. consts. at 20° were measured by the kinetic method. They were $K_1 = 7 \times 10^{-3}$ and $K_2 = 2 \times 10^{-14}$. Measurements of the rate of hydrolysis in alk. solns. of various OH^- concns. between 0.042 *N* and 0.476 *N* gave for the reaction velocity const. data that could be represented by the formula $k = (rg) / \{ [K_2' / (K_1 K_2 \text{OH}^{-2})] + [K_2' (K_2 \text{OH}^{-2})] + 1 \}$ where $(rg) = 0.249$. R. L. DODGE

Double decomposition between saline vapors; fumes formed from gaseous salts. A. TIAN. *Compt. rend.* 186, 1840-2 (1928); cf. C. A. 21, 3301.—Study is continued of the analogy between the reaction of salts in the vapor phase and in soln. The law corresponding to Berthollet's law is: The mixt. of 2 saline vapors can give a fixed salt by the exchange of their constituents and a decrease in volatility tends to det. the pptn. of the salt in fumes. By neglecting the actual vaporization of the salt occurring before the apparent vaporization, a simple law develops. The mixt. of 2 saline vapors

which gives by double decompn. a salt of a strong acid and base, tends to det. the pptn. of this salt in fumes. This conclusion was checked with the C_6H_5N , NH_3 , C_6H_5NH and Me_2NH salts of $HOAc$, $ClCH_2CO_2H$, HCO_2H and HCl . D. H. POWERS

The action of carbon dioxide on glass at high pressures. O. K. BOTVINKIN. *J. Russ. Phys.-Chem. Soc.* 60, 221-8 (1928).—One g. of powd. glass contg. 50.84% SiO_2 , 27.94% PbO and 15.19% Na_2O besides Al , K , Ca , Mg and Fe was covered with 10 cc. H_2O , subjected to 0-15 atm. of CO_2 for 1-24 hrs., filtered, and the filtrate titrated with HCl . Amts. of alkali plotted against time for 0, 5, 10 and 15 atm. gave almost parallel curves rising steeply at the origin and asymptotic to the time axis. The Na_2O -pressure curves are practically parallel to the axis of pressures. The action of H_2O and Na_2SiO_3 is accelerated by temp.; the amt. of alkali liberated after a given time interval is proportional to the temp. The total surface of the powder has a large influence on the velocity of hydrolysis. The CO_2 reaction const. decreases with time, probably because of diffusion through the carbonate formed followed by rhythmic pptn. The max. amt. of alkali dissolved was 10% of the total alkali. BASIL C. SOYENKOFF

Cryoscopic determination of the molecular equilibria of resorcinol and pyrocatechol in aqueous solution. F. BOURLON AND CH. TUTTLE. *Compt. rend* 186, 1124-6 (1928).—The equil. const for the change $nC_6H_6O_2 \rightleftharpoons (C_6H_6O_2)_n$ was studied. For resorcinol, from 0.75 to 3 M , and for pyrocatechol, from 0.375 to 1.25 M , $K = 3.5$ at 0° . This shows that there is equil. between single and triple mols. in each case ($n = 3$), just as at 100° $n = 2$ at low concn. and $n = 3$ at higher concn. The heat of assocn. is calcd. to be +600 cal./g. for resorcinol and -2400 cal./g. for pyrocatechol. Also in *J. chim phys.* 25, 485-96, 1928). E. G. VANDENBOSCHE

Equilibrium between metals and salts in fusion. VIII. Tin, lead, tin chloride, lead chloride. RICHARD LORENZ AND GEORG SCHULZ. *Z. anorg. allgem. Chem.* 170, 320-3 (1928); cf. *C. A.* 22, 2308.—The equil. is studied over the entire range of concn. at 500° and 600° , results being shown graphically. From calcns. based upon Lorenz' law of mass action, the following values of L and L' are obtained: at 500° $L = 0.0735$, $L' = 0.0949$; at 600° $L = 0.7732$, $L' = 0.3431$. The av. value obtained for the new const. are for 1, $k = 0.241$ and for 2, $k = 0.474$. IX. Zinc, cadmium, zinc chloride, cadmium chloride. *Ibid* 324-6.—This equil. is studied at 600° . The hygroscopic nature of both $ZnCl_2$ and $CdCl_2$ made the quantitative work difficult. From the results obtained and Lorenz' law of mass action, $L = -5.5938$ and $L' = -0.4421$. X. Establishment of equilibrium in fusions with aluminum as one component. *Ibid* 171, 258-60.— Al and the double chloride of Mg and K are heated at 700° but no reaction occurs, as is also the case with Al and $CaCl_2 \cdot 2NaCl$ at 800° . The reaction, $4Al + 3(Na_2SiF_6) + 6NaF = 4Na_3AlF_6 + 3Si$, is studied at 950° to 1000° , and proceeds quantitatively to the right. Sufficient Al was present to take up all the sepd. Si as the 10% eutectic, but this was not accomplished because some of the Na_2SiF_6 is always decomposed into NaF and SiF_4 , part of which is lost by vaporization. The failure to obtain equil. is attributed to the large difference in the heat of formation between $MgCl_2$ and $AlCl_3$ (21.4 cal.), $CaCl_2$ and $AlCl_3$ (41.5 cal.) and AlF_3 and SiF_4 (23.1 cal.). XI. Tin, cadmium, stannous chloride, cadmium chloride. RICHARD LORENZ, W. FRÄNKEL AND PAUL WOLFF. *Ibid* 355-63.—The effect of the addn. of Bi and alkali chlorides to the equil. $Sn + CdCl_2 \rightleftharpoons Cd + SnCl_2$ is studied. In the

equil. with addition of Bi , the relation $\frac{Bi}{Sn + Cd}$ in g.-atoms is taken as the measure of Bi , and 3 series are studied in which this relation is 6, 2 and 1. The equil. curve in which mol. % $CdCl_2$ is plotted as ordinate against atomic % Cd as abscissae, is displaced to the right with increasing addition of Bi . Addn. of an equimol. mixt. of $NaCl$ and KCl is studied at 650° . The equil. is displaced in the opposite direction to that produced by Bi , the max. displacement being obtained with the relation $\frac{NaCl + KCl}{SnCl_2 + CdCl_2} = 2$. With $LiCl$ the max. displacement is obtained with

$\frac{LiCl}{SnCl_2 + CdCl_2} = 1$ and is in the same direction as with $NaCl + KCl$. H. STOERTZ

Solid solution and compound formation. ALEXANDER LEHRMAN. *Chem. News* 136, 401-3 (1928).—In many cases, it is not realized that the compn. of a solid phase in equil. with solns. of varying compn., varies also, because ordinary analytical methods are not nice enough to make the distinction. The argument is presented from the point of view of the phase rule and is accompanied by diagrams. Numerous references are given, criticized and explained in the light of the failure to det. the min. soly. of a liquid phase in a solid phase. G. L. CLARK

The activation of hydrogen by the catalytic action of metals. M. V. TOLYAKOV. *J. Russ. Phys.-Chem. Soc.* 59, 847-9(1927); cf. *C. A.* 22, 1522.—"Catalysis at a distance" takes place when H_2 at 3 mm. is passed over hot Pd, Fe or Ni. On meeting a stream of air from a capillary a violet luminescence develops and heat is evolved, or H_2 flame appears in an excess of O_2 . The effect is most marked in the case of Pd. A very faint luminescence may appear in the absence of the metal. B. C. S.

Catalytic activity of titania in the reduction of nitro compounds. G. ETZEL. *J. Phys. Chem.* 32, 852-60(1928).—The reduction of $C_6H_5NO_2$ with titania as a catalyst has been thoroughly studied. The catalyst was prepd. by pptg. Ti hydroxide at the b. p. with NH_4OH from a soln. contg. 150 cc. of a 15% soln. of $TiCl_3$ dild. to 1000 cc. It was then reduced by H_2 at 302° . The rate of flow of H_2 was 14 l. per hour for a half-hour period. Reduction products formed were $C_6H_5NH_2$; $C_6H_5N.NC_6H_5$; $C_6H_5NHNHC_6H_5$; NH_3 and cyclo compds., $(C_6H_5)_2NH$, etc. Higher yields were obtained with 14 g. than with 6.8 g. of catalyst. The max. yield of $C_6H_5NH_2$ (94.4%) was obtained at about 282° with a non-ignited catalyst reduced at 302° . The optimum temp. of ignition of $Ti(OH)_3$ for production of $C_6H_5NH_2$ (from $C_6H_5NO_2$) was 100° . Catalysts ignited previously at 415° formed traces of $C_6H_5N.NC_6H_5$ and $C_6H_5NHNHC_6H_5$ from reduction of $C_6H_5NO_2$ at 245° and 266° . With the non-ignited catalyst none of these latter products was formed and less of NH_3 and cyclo compds. The best yield of $C_6H_5NH_2$ resulted with a flow rate of H_2 at 14 l. per hour with 14 g. of catalyst. A gradual drop occurred as the vol. of H_2 increased and a more sudden drop when it decreased. The optimum flow rate of $C_6H_5NO_2$ was 4.05 g. per hour (over 14 g. of catalyst). Continuous or intermittent flow of $C_6H_5NO_2$ made no difference in yield of $C_6H_5NH_2$. Activity of the catalyst increased by passing H_2 over it for 1 hour at 410° . The color of $C_6H_5NH_2$ varied from yellow to cherry-red as temps. increased from 260° upward. The asbestos support caused no change in the activity of the catalyst. Mn (5%) added to the catalyst did not increase the yield but improved the color of $C_6H_5NH_2$. A. J. CURRIER

Catalytic action of neutral salts. Effect of normal alkali sulfates on alkali acid sulfates in the ketonic splitting of ethyl acetoacetate. E. A. GOODHUE AND H. I. DUNLAP. Univ. of Missouri. *J. Am. Chem. Soc.* 50, 1916-22(1928).—An app. is described for accurately measuring the velocity of reactions at higher temps. and over a long period of time with substances evolving a gas. The effects of K_2SO_4 and Na_2SO_4 on their corresponding acid sulfates in the hydrolysis of $AcCH_2CO_2Et$ have been studied at 80° , 90° and 95° . The effect of the neutral salt on the rate of hydrolysis may be shown by calcg. the ratio of the time required with the acid sulfate plus the neutral salt for producing 75 and 150 cc. of CO_2 to the time required with the acid salt alone for producing the same quantity of CO_2 . For 0.2 N $KHSO_4$ and N KSO_4 , the av. ratio is 0.487 (75 cc.) and 0.483 (150 cc.); for 0.4 N $KHSO_4$, the av. values are 0.477 and 0.499. C. J. WEST

Catalysts for the formation of alcohols from carbon monoxide and hydrogen. Decomposition of methanol by catalysts composed of copper and zinc. PER K. FROLICH, M. R. FENSKE AND D. QUIGGLE. *Ind Eng Chem.* 20, 694-8(1928). A study of the catalytic decompn. of CH_3OH at 360° and 1 atm. with mixts. of ZnO and CuO in varying proportions indicates that the max. decompn. and formation of CO occur when the ZnO is present in excess. At 40-50 mol. % ZnO, the mols. CO formed per mol. CH_3OH increase about 350%. The addn. of a small amt. of ZnO to CuO very markedly increases the decompn. of CH_3OH . A catalyst consisting of 3 mols. % ZnO and 97% CuO decomposes 26% of the CH_3OH , while pure Cu decomposes only 9% under similar exptl. conditions. A mixt. containing 98.6 mols. % ZnO and 1.4 mols. % CuO decomposes 41% of the CH_3OH , whereas pure ZnO decomposes 33% under similar exptl. conditions. Cu promoted with ZnO favors formation of $HCOOCH_3$; and CO formation is favored by ZnO promoted with Cu. J. H. PERRY

Acid and salt effects in catalyzed reactions. XII. Water catenary ($H^+ - H_2O - OH^-$) in the ionization of acetone. HARRY M. DAWSON AND ARTHUR KEY. *J. Chem. Soc.* 1928, 543-51; cf. *C. A.* 22, 716. — The rate of reaction of acetone with I in isohydric buffer solns. has been detd. with an acetone concn. of 20 cc./l., I concn. initially of 0.001 M, and H-ion concns. between 18.5×10^{-5} and 0.065×10^{-5} . The velocities due to the different catalytic constituents of H_2O have been calcd. by means of the equation: $V_0 = k_1(H^+) + k_{OH}(OH^-) + k_w(H_2O)$. H_2O mols. accelerate the reaction rate although k_w is small. The ratio k_{OH}/k_w is approx. 5×10^{10} . The velocity due to the combined effect of H^+ and OH^- agrees with the values calcd. from the formula $r = \cosh \log n$, where r = reduced ionic velocity and n = reduced H^+ concn. XIII.

Inert salt effects in the catalytic action of acids. HARRY M. DAWSON AND ARTHUR KEY. *Ibid* 1239-48.—Measurements are reported on the velocity of the acetone-iodine reaction when catalyzed by HCl, dichloroacetic, monochloroacetic and acetic acids in solns. of NaCl of 0-4 molar. The character of the influence of the NaCl (inert catalytically) depends upon the strength of the acid. By assuming that the increase of the rate of reaction caused by adding inert salts to a strong acid is due to a change in the catalytic activity of the H^+ ion, it is shown that the ionization const. of a weak acid is first increased and then decreased with progressively higher salt concns. The study of the catalytic properties of mixts. of weak acids and their corresponding salts is not affected by such inert salts as the alkali chlorides. XIV. **Influence of inert salts on the catalytic catenary for acetic acid-acetate mixtures.** *Ibid* 1248-57.—The influence of catalytically inert salts on the velocity of the acetone-I reaction has been studied in the presence of a weak acid and in the presence and absence of the corresponding salt. The relations in the NaCl solns. from 0.1 to 4.0 *M*, are very similar to those obtained with pure aq. solns. The coeffs. detg. the catalytic activity of the AcOH mol. and the AcO^- ion are only slightly affected by the presence of NaCl. But the catalytic activity of the H^+ ion and the degree of ionization of the AcOH vary considerably with the salt concn. The velocity- p_H curves are all catenaries for, although the isocatalytic activities vary with the salt concns., the variations are small. J. H. PERRY

The catalytic decomposition of oleic acid. B. M. MARKS AND H. C. HOWARD, JR. *J. Phys. Chem.* 32, 1040-8 (1928).—As a preliminary in the study of the hydrogenation of sunflower-seed oil which consists of glycerides of oleic and related acids, the catalytic activity of Ni toward oleic acid was studied through a temp. range of 200° to 490°. The decarboxylating catalysis of Ni has been demonstrated for oleic acid, the products of catalytic decompn. being, mainly, CO, water and hydrocarbons. Analytical data are given for the products of reaction as well as an explanation of the observed data. G. L. CLARK

The electrodynamics of surface catalysis. A. K. BREWER. *J. Phys. Chem.* 32, 1006-17 (1928).—This paper is a summary and conclusions drawn from exptl. material previously published. Certain observed facts, namely, the emission of ions during various surface-catalyzed chem. reactions following an equation of the Richardson type, and the concn of the ions increasing as the inverse cube of the distance upon approaching the surface, have been made the basis for the proposed mechanism of surface catalysis. The mechanism of catalysis as brought out is briefly that the image and intrinsic surface forces combined with kinetic energy of agitation dissociate the gas mols. on the surface into ions; the ions thus formed are driven from the surface by kinetic agitation with a probability distribution of velocities; and that chem. action results from a rearranged combination of the ions whose velocity components perpendicular to the surface are sufficient to carry them out to a region of weak surface forces—the chemically active region. Thus it is possible to treat chemical action as a special case of thermionic emission. The equation for the rate of the forward reaction developed from the thermodynamic point of view is: $dC'/dt = A'T^{3/2} e^{-b'/T}$, where A is the combination factor and b is the complete chemical work function. Equilibrium is expressed by: $K = (A'/A'')T^{(n''-n')/2} e^{-(q-b')/T}$. G. L. CLARK

Further remarks on the method proposed by Swietosławski for the correction of the older thermochemical data. P. E. VERKADE AND J. COOPS, JR. *Rec. trav. chim.* 47, 701-8 (1928).—The authors criticize the methods proposed by S. for correcting the thermochem. data of the older investigators (Zubow, Swarts, Richards, Berthelot and Matignon) using correction coeffs., on the ground that only one comparison substance is used. S. gives a correction coeff. for all of Zubow's data (Zub. = 0.9903) derived thus: heat of combustion of naphthalene, 9706 cal. per g. (air) (Zubow) and 9612 15°-cal. per g. (Swi.) 9612/9706 = 0.9903. S. corrects all of Zubow's data by this one coeff. The authors maintain that if the data of an investigator are to be reduced to the international standard, the comparison substances chosen should be well distributed over the entire work of the investigator. A. J. CURRIER

The ratio of the heats of combustion of benzoic acid and salicylic acid. P. E. VERKADE AND J. COOPS, JR. *Rec. trav. chim.* 47, 709-14 (1928).—The heat of combustion of salicylic acid (previously detd. by the authors), viz., 5241.9 15°-cal. per g. (air) has been redetd. The new value is 5241.3 15°-cal. per g. (air). The ratio of 6324/5241.0 = 1.2064 (air) for the old value is stated, using 6324 cal. as the heat of combustion of benzoic acid (international standard). The lower value obtained by Berner, 5237.3 15°-cal. was thought to be due to a small systematic error and confirmed by the authors by data obtained from naphthalene and from two substances previously investigated by Berner, the heats of combustion for which were found to be too low. A. J. CURRIER

The true temperature scale of carbon. C. H. PRISCOTT, JR., AND W. B. HINCKE. Calif. Inst. Tech. *Phys. Rev.* 31, 130-4(1928).—The spectral emissive power of Acheson graphite for the wave length 0.660μ has been detd. for the temp. range from 1250° K. to 2700° K. The observations were made on a small tabular graphite resistance furnace with a hole in the wall and are best summarized by the relation: $\epsilon = 0.984 - 5.8 \times 10^{-6}T$. Measurements of the temp. distribution along the furnace afford detns. of the ratio of resistivity to thermal cond. at 3 temps. BERNARD LEWIS

The thermal and electrical conductivity of fused quartz as a function of temperature. HERMAN E. SEEMANN. Cornell Univ. *Phys. Rev.* 31, 119-29(1928).—The thermal cond. as a function of the temp. has been detd. for clear fused quartz by a radial flow method from 235° K. to 1225° K. The specimen was in the form of a hollow cylinder closed hemispherically at one end. Energy to maintain a steady temp. gradient was supplied by means of an electrically heated filament mounted axially inside the specimen. Thermal contact with the specimen was made with Hg inside and outside at the lower temps. and with the Sn-Pb eutectic at higher temps. Inside and outside temps. were obtained with thermocouples. A guard-ring scheme was used to prevent heat loss or gain at the open end of the cylinder and correction was made for the heat flow through the hemispherical end cap. The results may be represented by the linear equation: $K = 3.83 \times 10^{-6}T + 0.00163$. An abrupt change in the thermal cond. was noted in the vicinity of 1140° K. which is attributed to heat treatment *i. e.*, annealing or partial crystn. An attempt was made to measure the sp. elec. resistance as a function of the temp. by the same method at the same time. The results were not conclusive because of the small no. of data taken but there is every reason to believe that the method would be entirely successful for the detn. of both quantities. The sp. resistance was measured for a small piece of the original specimen. The modified Königsberger formula was verified, *i. e.*, $\rho = A\epsilon(Q/RT + aT)\rho = A\epsilon(Q/RT + aT)$. The results indicate the presence of both electrolytic and dielec. polarization. Certain peculiarities in the polarization were noted at about 1140° K. as well as a general change in the resistance-temp. curve due to heat treatment. The interpolated results are:

Temp. °K.	550	750	950	1150
Sp. resistance	4.46×10^9	2.09×10^7	1.35×10^6	2.89×10^5

BERNARD LEWIS

A new method for the measurement of the temperature of gases. MARCEL CHOPIN. *Compt. rend.* 186, 1830-2(1928).—To avoid errors in temp. measurement of gases the flow of gas through an orifice at two temps. is used to det. the temp. accurately. The formula $Q = SK\sqrt{p/T}$ is used where Q is wt. of gas passing through the orifice, S is the cross section of the orifice and K is a coeff. dependent on the given gas. A gas is first passed through an orifice at a given temp. and is then passed through an orifice in the region where the temp. is desired. With an equal wt. of gas passing through both orifices: $SK\sqrt{p/T} = S_1K_1\sqrt{p/T_1}$. After heating these values become $SK\sqrt{p_1/T_2} = S_1(1 + at)^2K_1\sqrt{p_1/T_2}$ and $T_2 = pT_1/p_1T$. $p_1/p_2(1 + at)^2T_2$. The term pT_1/p_1T is const. and $(1 + at)^2$ is very close to unity. D. H. POWERS

The latent heat of fusion of naphthalene from new solubility data. A. A. SUNIER AND C. ROSENBLUM. *J. Phys. Chem.* 32, 1049-55(1928).—The soly. of naphthalene has been detd. in $(\text{CH}_2\text{Cl})_2$, $(\text{CH}_2\text{Br})_2$, MeCHCl_2 and MeCHBr_2 and the slopes of the upper portion of log N vs $1/T$ curves have been calcd. These indicate that the molal heat of fusion of naphthalene is 4440 cal. G. L. CLARK

A critical study of the experimental investigations on the heat of formation of liquid water and of carbon dioxide. MORRIS W. TRAVERS. *J. Inst. Fuel* 1, 279-87(1928).—The available data are critically reviewed. The heat of formation of liquid water is concluded to be 68,485 15° -calories at 0° and 68,345 15° -calories at 18° . The heat of combustion of carbon in coke is taken to be 94,750. LESLIE B. BRAGG

Contribution to the theory of the melting process and of the specific heat of liquid metals. A. MAGNUS. Univ. Frankfurt a/M. *Z. anorg. allgem. Chem.* 171, 73-81 (1928).—M. discusses several theories advanced to elucidate the melting of solids, such as the kinetic interpretation of Lindeman (*C. A.* 4, 2593) and the quantum expositions of the phenomenon. A question arises as to whether the lattice is completely disrupted at the m. p., or whether "fragments of the lattice" remain, this debris disappearing upon further rise of temp. of the melt. M. applies quantum considerations to the change of internal energy with temp. by use of the formula for the energy of N atoms (or oscillators) with 3 degrees of freedom, $U = 3N[h\nu/(e^{h\nu/kT} - 1)] + U_0$. Tests of the theoretical material with the data for Hg (liquid) reveal a fair

agreement. The discrepancies may be attributed to the incomplete destruction of the lattice at the m. p., more than the theoretical amt. of energy being required for C_p of the liquid since addnl. energy for the disruption of the lattice fragments must be supplied. Theoretical corrections, applied on the basis of this assumption, are in accord with expt.

WILLIAM E. VAUGHAN

Measurement of the true specific heat of nickel by a direct electrical method. (MME.) CH. LAPP. *Compt. rend.* 186, 1104-6 (1928).—A pure Ni wire, 2 mm. in diam. was placed in an oven at uniform temp. and then heated for a short time; from the energy furnished the wire and its rise in temp. the sp. heat is easily calcd. The sp. heat at 175° is 0.0550 and this rises to 0.1557 at 353.3°, corresponding to the Curie magnetic point; then there is a sudden drop to 0.1252 at 360.5° and rise again to 0.1288 at 460°, the latter rise in the paramagnetic region.

E. G. VANDENBOSCHE

Attempt of a quantum theory for gases and solutions. N. BARBULESCU. Univ. of Cluj. *Bul. soc. stiinte Cluj* 4, 62-74 (1928).—The difficulty in establishing a quantum basis for the theory of liquids and gases has existed in the idea that the energy of translation of the mols., as opposed to that of vibration and rotation, is continuous as required by the principle of equipartition. For actual matter, however, B. shows that there exists a force of cohesion which tends to hold the mol. in the position which it occupies at the time of the arrival of the energy wave. The intensity of the field of cohesion varies with the state of aggregation. For liquids and gases the movement of translation of the mols. represents a vibratory movement of an extremely small frequency. On the basis of this idea, assuming as a first approximation that the vibrations are monochromatic, an equation of state for gases is derived. The active mass of a gas is shown to be the product of the concn. into a term involving the vibrational frequency. A new formula for sp. heat is also derived. By applying the same ideas to solns., equations which have a greater validity are derived for osmotic pressure, etc. The idea of Longinescu and Chaborski (*C. A.* 21, 3004), that mol. assocn. is due to the accumulation of mols. into a given vol., is supported.

H. F. JOHNSTONE

Calculation of the energy of dissociation of diatomic molecules. A. CARRELLI. *Nuovo cimento* [N. S.] 5, 9-13 (1928).—A math. discussion of the sign of the terminal corrective in the formula for the energy of dissociation of a diat. mol.

L. T. F.

The theory of Born-Landé lattice forces. ALBRECHT UNSÖLD. *Naturwissenschaften* 15, 681-2 (1927).—A short review is given of the author's work (*C. A.* 21, 2096, 22, 536) on the detn. from quantum mechanics of the Born-Landé b/r^n repulsive force between atoms at short distances. The potential of this force (energy of perturbation) in its general form is found to be $(e^2Z/a)c^{-r}[(8/r) + 6 + 2r + (r^2/2)]$ for r = nuclear distance times Z_{eff} /hydrogen radius a . As appears from the derivation the repulsive force has no directional effect. This approx. equation represents the exptl. data on the Born factors n satisfactorily; it makes them rise with increasing ratio of ion radius to ion distance.

B. J. C. VAN DER HORVEN

The internal pressure and thermal oscillations of solids. E. N. GAPON. *J. Russ. Phys.-Chem. Soc.* 59, 933-49 (1927).—By assuming that only $1/3$ of the heat energy is used in overcoming internal pressure, the Richards formula is made to read $P = C_p(dT/dV)/3$ (1). Since $(dV/dT) = \alpha V$, the equation of Traube $(\alpha V/\Phi) = 1/3n$ is obtained if $C_p = 6$. According to Grüneisen, $\alpha = \text{const.} \times C_p$. By neglecting the difference $C_p - C_v$ from (1): $[d(PV)/dT] = 0$. Another equation of Grüneisen leads to $P = 588.7\lambda_0/v$ (2). P being in atm. per sq. cm., $PV^{1/3}$ is termed mol. internal pressure. G. points out that $PV^{2/3} = 600T_0$ (3) (where T_0 m. p. in °K.) quite closely for the metals, P being obtained from (2). P increases with the at. wt. in Ga-Tl, Fe-Os, Co-Ir, V-Ta; declines with the increasing at. wt. in Be-Ba, Zn-Hg, B-La, C and Si, Ti-Th. Other groups show min. or max. From $P\Phi = RT$, where Φ is the covol. ($v - b$), and (1) the following relationship is obtained: $(\alpha V/\Phi) = (14.13 C_v/RT)$. Or, the coeff. of expansion of Φ is proportional to at. heat. If $P\beta = \text{const.}$ (4), $(\beta T_0/v^{1/3}) = \text{const.}$, where β is the compressibility. The value of the const. for metals actually varies between 0.00021-0.00030, the mean being at 0.000265. If a mol. contains n atoms, equation (3) becomes $P = 600T_0/(nV^{1/3})$. Combining it with (2), G. has $n = 1.029[T_0V^{1/3}/(M\lambda)]^{3/2}$, from which n is computed for the alkali metals (Li 10.5, Na 2.3 etc.). Equation (3) is modified to apply to binary salts: $P = n^{1/2}T_0/v^{1/3}$. P of the alkali halides declines in the series Cl-I and Na-Cs. The covols. of salts follow roughly the additive law. The following relationship holds within 5%: $\sigma_K \times \sigma_A \times P_{KA} = 8.6 \times 10^4$ where σ is ionic diam. From (1) and (4) results $[\alpha V/(\beta C)] = 90.6$ (5), which has been obtained by Mie from different premises. α of complex compds. deviates little from the mean of 0.0038. Ice is a complex of the formula $(H_2O \dots H)_xO$. From the expression of Lindemann for ν , and Guldberg's

$\lambda_g = [E/(40d)]$, G. deduces $\nu = 5 \times 10^{11} \sqrt{E/M}$ besides the following empirical relationships: $\nu = 10.5 \times 10^{12} (C_p/M) \sqrt{d(C_p - C_v)} = 6.24 \times 10^{15} / (DM^{1/2})$. E denotes the modulus of elasticity, D diffusion coeff. of the metal into Hg at room temp., M at. wt., ν frequency of at. vibration. From (5) and $C_p = C_v + TV\alpha^2/\beta$ follows $C_p = C_v(1 + 2\alpha T)$, or C_p/C_v is a linear function of temp. G. obtains $\lambda_g = 0.074 \sqrt{\beta/n}$ where λ_g is wave length in the ultra-violet; the equation holds for Na, K, NaCl and KCl within 5%. For binary compds. $P = 1.05 \times 10^{-6} \times V^{1/2} (C_{11} + C_{12} + C_{44}) / (Z_1 Z_2)$ where Z_1 and Z_2 are the mol. fractions.

A generalization of the third principle of thermodynamics. N. A. KOLOSOVSKIĬ
J. Russ. Phys.-Chem. Soc. 59, 741-53 (1927).—See *C. A.* 22, 1069, 1267, 2090.

B. C. SOYENKOFF

The second law of thermodynamics in chemistry. R. C. CANTELO. *J. Phys. Chem.* 32, 982-9 (1928).—A clear, concise statement is given of the second law of thermodynamics. The concepts and the mathematical expressions are developed from the point of view of classical thermodynamics; then their application to chemistry is simply and thoroughly presented and discussed.

G. L. CLARK

Thermodynamics of air separation. BARNETT F. DODGE AND CHEVOWETH HOU. *Trans. Am. Inst. Chem. Eng.* 19, 117-51 (1927).—The theoretical work necessary for the sepn. of air into O_2 and N_2 by a reversible liquefaction process is equal to 2.60 h. p. hrs. per 1000 cu. ft. O_2 . It is shown by thermodynamic analysis that the present low energy efficiency (10%) of liquefaction processes is due to the multiplication of a no. of high and moderate efficiency terms and that any great increase in the overall efficiency is not to be expected over perhaps to 13-15% efficiency. This apparently small increase, however, should reduce the cost of O_2 very materially.

J. H. P.

The study of the specific resistance of bismuth crystals and its change in strong magnetic fields and some allied problems. I. The growth of crystal rods with a definite orientation of the crystal planes and the specific resistance of bismuth crystals. P. KAPITZA. *Proc. Roy. Soc. (London)* A119, 358-86 (1928).—During the growth of Bi crystals, a small strain in the material influences greatly the orientation of the trigonal axis of the crystal lattice. According to the character of the strain, the perfect cleavage plane is changed from one of the pseudo-octahedral planes to one of the 3 remaining planes of the same pseudo-octahedron. In order to obtain crystal rods with the perfect cleavage plane having any desired orientation relative to the axis of the rod, no strain must be set up in Bi during crystn., and a method is described by which this is effected. During growth, cracks and imperfections are developed in the lattice, which account for the variations in the sp. resistance of Bi previously observed. For a perfect crystal, the sp. resistance along the trigonal axis is $1.38 \times 10^{-4} \pm 1\%$, and perpendicular to the axis $1.07 \times 10^{-4} \pm 1\%$ at 16° . The cracks are produced during cooling at a temp. very near the solidification point, and their character depends chiefly on the temp. gradient at the point where the Bi is crystallized. A perfect Bi crystal at room temp. probably has no well-defined cleavage plane and is very flexible. To explain the origin of the cracks, it is proposed that Bi exists in 2 modifications. The one now unknown (probably cubic) changes to the ordinary rhombohedral form at a temp. slightly below the melting point. The transition involves a change in shape which produces the cracks. This hypothesis, together with the observed phenomena, leads to an explanation of several physical properties of Bi. **II. The method and apparatus for observing the change of resistance of bismuth in strong magnetic fields.** *Ibid.* 387-401.—A method is described for measuring the change of resistance of a conductor when placed in a magnetic field which exists for $1/100$ sec. For such a short time, larger c. ds. can be used without heating and specially sensitive app. is not required. The measurements can be made with an oscillograph. The design of a special switch is given, which permits the current to be sent through the conductor for the short interval during which the field is applied, the time adjustment being very accurate. The exptl. arrangements for studying the change of resistance of Bi crystals in a magnetic field at different temps. are described, and the elimination of errors due to heating by induction discussed. **III. The change of resistance of bismuth and the time lag in magnetic fields.** *Ibid.* 401-43.—Exptl. results are given for the change of the resistance of Bi crystals at 290° , 193° and 91° K. when the current is perpendicular to the magnetic field, for different orientations of the crystal axis relative to the field. Impurities and imperfections in the lattice have a large effect on the change of resistance, particularly with low temps. and strong fields. In an ideal perfect crystal, the change of resistance in weak fields follows a square law, and in strong fields a linear law. The latter is almost independent of the orientation of the crystal axis. The

change of resistance when the current is parallel to the magnetic field, with different orientations of the crystal, is also measured, and a "satn effect" is found. In this case, the resistance change is small and depends only slightly on temp., but is strongly affected by imperfections in the crystal. The observed resistance change may be due entirely to imperfections and lack of complete alignment of the current and magnetic lines of force. An unsuccessful attempt to make perfect Bi crystals by condensation of the vapor in vacuum is described. By studying the change of resistance in strong magnetic fields of the deposits obtained, certain phenomena previously observed in thin Bi layers are explained. The residual e. m. f. which occurs in Bi in a magnetic field when a current is passing, and which accounts for the time lag, is roughly detd. The ratio of this e. m. f. to the resistance is independent of the strength of the field, but depends greatly on the orientation and perfection of the crystal. A general discussion is given of the failure of the present theory of metallic conduction to account for the phenomenon of the change of resistance in a magnetic field, and various suggestions are made in this connection.

F. A. JENKINS

The decomposition of carbon dioxide at low pressures under the action of an electric current. PIERRE JOLIBOIS, HENRI LEFEBVRE and PIERRE MONTAGNE. *Compt. rend.* 186, 1119-21 (1928); cf. *C. A.* 21, 1914.—With currents up to 0.002 amps. the disson. of CO_2 at 3.4-mm. initial pressure is 42% and independent of the current, though equil. is reached more readily with a high current. The initial pressure affects the disson. (54% at 0.8 mm. and 31% at 8 mm., around 2300°). The efficiency of the d. c. is much less than that of the discharge from a condenser.

E. G. VANDENBOSCHE

Temperature variation of the electrical conductivity of crystals. N. USSATAJA and B. HOCHBERG. *Z. Physik* 46, 88-92 (1927); *Science Abstracts* 31A, 293.—For NaNO_3 , CaI_2 and NaCl the elec. cond. decreases regularly with increasing temp., and the consts. are practically equal. For mica the cond. diminishes much more slowly.

H. G.

Salt-like hydrides. IV. I. KAZARNOVSKII. *Z. anorg. allgem. Chem.* 170, 311-9 (1928). The normal potential of the negative H ion (O^{H}) in hydrides such as LiH is calcd. from the heat of formation, soly and free energy of the ions, and is found to be 2.38 v. It is thus the weakest of the metalloids. The hydration energy is given by the expression $W_{\text{H}^-} = (\text{O}^{\text{H}} - \text{O}^{\text{Na}})23 + S'_{\text{Na}} + I'_{\text{Na}} + D'_{\text{H}_2\text{O}} - E'_{\text{H}} - W_{\text{Na}^+}$, in which D'_{H} is the free energy of H disson. = 47 kg.-cal., E'_{H} is the electron affinity of H and = 0, O^{Na} is the normal potential of Na = -2.712 v., S'_{Na} is the free energy of sublimation of Na = 19 kg.-cal., W_{Na^+} is the energy of hydration of Na = 99 kg.-cal., I'_{Na} is the energy of ionization of Na = 117 kg.-cal. The value obtained for W_{H^-} = 91.5 kg.-cal. The hydrides are completely hydrolyzed by H_2O : $\text{NaH} + \text{H}_2\text{O} = \text{NaOH} + \text{H}_2$. Calcn. of the heat of formation of the hypothetical hydride NH_2H gives 196 kg.-cal., while that of MgH_2 is found to be about 0. The lattice energy in kg.-cal. is given for LiH —calcd. 234, observed 234, for NaH —calcd. 211, observed 210; for RbH —calcd. 169, observed 178; for BaH_2 —calcd. 551, observed 526.

H. STOERTZ

The limiting potential of solutions of glucose. RENE WURMER and JEAN GELOSO. *Compt. rend.* 186, 1842-4 (1928); cf. *C. A.* 21, 1467. In studying the potentials of glucose (I) solns. with various dyes it was found that these dyes have a catalytic effect on the speed of establishing the potential, and if the measurements are sufficiently prolonged the final potential reaches the same limit in a soln. of I with or without the dye. A limiting potential of p_{H} 7 was obtained after 30 days at 40° , 9 hrs. at 75° or 2 hrs. at 90° . The temp. coeff. of p_{H} of I with a phosphate buffer is $(500/T) - 8.8 \pm 0.5$. The curves indicate that the dye has no effect on the final potential. The leuco form of Janus green and phenosafranine whose potentials are more neg. than I are reoxidized by it, as if I yielded a true reversible form.

D. H. POWERS

The oxygen electrode as a quasi-quantitative instrument. W. T. RICHARDS. *J. Phys. Chem.* 32, 990-1005 (1928).—The methods of prepn. of an O-Pt electrode capable of giving reproducible results is discussed along with the types of solns. in which it works best. The operation and construction of a convenient cell chain having a flowing junction and requiring only small vols. of liquid is described. Although far below the thermodynamic value for the O-H chain, it has been demonstrated that, under suitable conditions, O electrode potential const. to a millivolt for many days may be obtained. The potential of the O electrode has been shown to vary quant., but not thermodynamically, with the partial pressure of O gas between 0 and 1 atm. A method is described for measuring *OH-ion activities* with the O electrode which is capable of some accuracy. It is hoped that this method will prove useful in biochem. work. In order to explain the results it is necessary to attribute electromotive activity

to O gas, and to consider the measured potential of the electrode a compromise between this and the oxidic potential.

G. L. CLARK

The preparation of the hydrogen electrode and the removal of a common source of trouble in connection with its use. S. POPOFF, A. H. KUNZ AND R. D. SNOW. *J. Phys. Chem.* **32**, 1056-60(1928); cf. *C. A.* **21**, 3807.—The following technic in the prepn. and use of the H electrode is established as good practice: (1) Equil. is attained more quickly in a Bovie titration cell than in an open beaker. (2) A preliminary plating of gold on the electrodes does not affect the time required for the attainment of equil. but causes a more adherent coating of Pt black to be deposited which is more easily removed in cleaning. (3) A thinly coated electrode is more desirable than a heavily coated one, and should be deposited from a soln. of 0.5 cc. of 0.1 N Pb acetate soln. in 100 cc. of 3% H_2PtCl_6 soln. (4) Poisoning due to HgCl_2 can be removed by treatment with HNO_3 or dichromate cleaning mixt. Directions are also given for plating the electrodes

G. L. CLARK

The electrochemical behavior of silicate glasses. V. J. B. FERGUSON, M. J. MULLIGAN AND J. W. REBBECK. *J. Phys. Chem.* **32**, 1018-30(1928).—When a glass sample is electrolyzed at moderate temps. with a difficultly sol. anode material like Hg, the current decreases as the electrolysis proceeds. This decrease is caused by the setting up of counter e. m. fs. and by an increase in the true resistance of the glass sample. At low voltages the counter e. m. f. tends to assume a const. value. The min. voltage which is required to give this nearly const. value increases as the electrolysis proceeds. The true resistance of a Hg-containing anode glass layer has been found to be many times that of the original glass and to change with temp. in accordance with the rule of Rasch and Hinrichsen. The smaller counter e. m. fs. const. values which are noted when glass samples are electrolyzed with a sol. anode and a mercury cathode have been attributed to chem. origin. The manner in which the elec. measurements are affected by current reversal has been indicated for glass samples having Hg-contg. anode glass layers. Hopkinson's expt. on residual charge was repeated under different conditions.

G. L. CLARK

A new method of measurement of the dielectric constants of liquids. P. V. GOLUBKOV. *Ber. Saratower Naturforscherges.* (Russia) **1**, No. 4, 37-51(1925); *Chem. Zentr.* **1927**, I, 144.—The method is based on the resonance principle, but instead of detg. the max. amplitude of the galvanometer in its resonance cycle, the throw of the galvanometer ϕ is detd. when the condenser is filled with air ϕ_0 , with a liquid of reference ϕ_1 , and with the liquid to be tested ϕ_2 . From these values the dielec. const. ϵ_2 can be calcd. from the relation: $\epsilon_2 = (\epsilon_1 - 1)[(\phi_2 - \phi_0)/(\phi_1 - \phi_0)] + 1$, where ϵ_1 is the dielec. const. of the liquid of reference. This is in the range where the throws of the galvanometer are directly proportional to the capacity of the condenser. C_6H_6 was chosen as the liquid of reference. The values for CS_2 were 2.6606, 2.6608 at 11° and 2.6587 at 12°. For the mixt. CS_2 20 + C_6H_6 80 (by wt.) it was 2.3713; for CS_2 40 + C_6H_6 60 it was 2.4396, for CS_2 60 + C_6H_6 40 it was 2.5041, for CS_2 80 + C_6H_6 20 it was 2.5950; and for pure CS_2 it was 2.6739 (at 11°).

C. C. DAVIS

Thermomagnetic study of the sesquioxide of iron attractable by a magnet. J. HUGGETT AND G. CHAUDRON. *Compt. rend.* **186**, 1617-9(1928).—The method of prepn. has great influence on the properties of the magnetic form of Fe_2O_3 originally discovered by Malaguti. Details of prepn. are given for 2 specimens which were subjected to thermomagnetic analysis. In one the magnetism reached a max. at approx. 350° and then fell to practically zero at about 600°. The process was accompanied by a liberation of heat between 350° and 450°. Since on cooling the magnetism is not recovered, this is interpreted as a transformation of the Malaguti form into the ordinary Fe_2O_3 . The other specimen showed a more or less steady rise in magnetism up to approx. 450°, then a more rapid increase to a max. a little below 550°, followed by a rapid drop to zero at about 620°. On cooling the magnetism increases rapidly to about 500° and then more slowly, the final value at room temp. being approx. $2\frac{1}{2}$ times the initial. If heated to 700° this form is transformed, with evolution of heat, into ordinary Fe_2O_3 . The variations in behavior of the two specimens are ascribed to impurities. Cf. *C. A.* **22**, 1934.

W. W. STIFLER

A study of the nightly fluctuations of atmospheric ozone. DANIEL CHALONGE. *Compt. rend.* **186**, 1856-8(1928).—Detns. of the ozone content of the atmosphere were made spectroscopically by photographing the moon, using the spectral region 3100-3250 Å. U. The results indicate that the upper atmosphere never contains less ozone at night than in the day time. The concn. at night shows no marked seasonal variation over the period studied, from October, 1927 to April, 1928. Creation and fluctuation of ozone at a high altitude must then be explained by other causes than solar ultra-violet radiation.

D. H. POWERS

Valency and refraction equivalents. K. v. AUWERS. *Ber.* 61B, 1041-9(1928).—The following new exptl. detns. are used as a basis to discuss the influence of the N valency on the refraction exhaltation.

	M_a	M_D	$M_D - M_a$

3—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

S. C. LIND

Secondary variations in cosmic radiation. AXEL CORLIN *Naturwissenschaften* 16, 512(1928); cf. *C. A.* 21, 2218. —Irregular variations in cosmic radiation are discussed; they are of an amplitude occasionally double that of the variations with stellar time.

B. J. C. VAN DER HOEVEN

The quantum postulate and atomic theory. F. J. SELBY. *Nature* 121, 828(1928). — A discussion of Bohr's paper (cf. *C. A.* 22, 2313), in which it is emphasized that the duality of observed phenomenon and observing mechanism is connected with a third factor, the conscious mind of the observer. It is shown that the origin of the quantum can be explained in these terms.

F. A. JENKINS

Temperatures of melting and of boiling of homopolar compounds considered as a function of the distribution of electrons in the molecule. A. DUBROVA. *Ukrainskii Khim. Zhurnal* 3, No. 1, Sci. Pt. 1-38 — On the basis of the ideas of N. Bohr on the structure of atoms and on the ideas of Remy on the structure of mols. of homopolar compds., D. affirms that the properties of homopolar compds. can be represented in the form of the function $q = f(N_m, N_a, N, K)$, where q is the magnitude of the property, N_m the no. of electrons in the system of mol. union, N_a the no. of electrons remaining unaffected by the chem. process at the at. nuclei, N the no. of charges of at. nuclei, and K a magnitude wholly dependent on external conditions. To prove this assertion D. takes the temps. of melting and boiling of homopolar compds., preferably of homologous series, and establishes for them formulas which have the following general appearance: M (or b). p. = $f(N, P)(N_a/\sqrt{N_m})$, where P stands for pressure. It thus becomes evident that the temps. of m . p. and b . p. of homopolar compds. are really functions of distribution of electrons in the mol. between the system of mol. union and the systems of at. centers. When $P > 0$ and $P = \text{const.}$, $f(N, P)$ is in homologous series a linear function which, though not exactly always equal, differs but little for various compds. In absence of association of mols. the magnitude $f(N, P)$ is below 40 for the b . p. and below 30 for the m . p., P being not above 760 mm. When $P = 0$, the m . p. and b . p. of homopolar compds. are only directly proportional to the multiplication factor of repartition (distribution) of electrons in the mol., $N_a/\sqrt{N_m}$, since in that case $f(N, P) = \text{const.}$ For the b . p. it is approx. equal to 20. When P is variable $f(N, P)$ has, for the b . p., rather the appearance $f(N, P) = a[(b - N)\sqrt{P} + d]$, where a , b and d are consts. characteristic of the homologous series given, $a \cdot d = \text{const.} = \text{about } 20$. The nos., N_m and N_a were detd. not only on the basis of the theory of valency, but also by taking into consideration the properties of elements and their compds.

BERNARD NELSON

The production and measurement of molecular beams. THOMAS H. JOHNSON. Yale Univ. *Phys. Rev.* 31, 103-14(1928); cf. *C. A.* 21, 2422. — A new method for studying mol. beams has been developed in which the beam is detected and its intensity measured by the increase in pressure which is produced in an ionization gage when the gage is moved to allow the beam to enter it through a narrow slit. This method has the advantage over other methods in use in that it is applicable to beams of mols. of non-condensable and chemically inactive gases. Many details of the construction of the new beam detector have been described and the characteristics of its operation have been studied both experimentally and theoretically. Simple kinetic theory fails to explain the observed pressure changes unless adsorption on the inner walls of the gage is taken into account. A satisfactory hypothesis for interpreting the observations is that gas is adsorbed by the walls at a rate which is proportional to the mol. d. in the vol. of the gage and liberated at a rate proportional to the no. of adsorbed mols. A value of 10^{-4} per collision is found for the probability of adsorption of a Hg mol. on glass. The sensitivity of the gage method of detecting a beam, although seriously impaired by adsorption still compares favorably with that of other methods in use.

A study of the relation between the beam intensity and the pressure in the source chamber has been made in which the ionization-gage method has been used for the measurements.

BERNARD LEWIS

Some experiments on the separation of the isotopes of chlorine by chemical methods. TSUNEKICHI NISHIMURA AND TORINOSUKE TOYAMA. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 98-108(1928); *Abstracts* 1, 6-8.—N. and T. tried to sep. the isotopic forms of Cl by taking advantage of the soly. of HCl in aq. FeCl_3 solns. and also by forming solid salts of Mg oxychloride and carnallite. No success was obtained.

A. L. HENNE

Some experiments attempting to separate the isotopes of magnesium by chemical methods. TSUNEKICHI NISHIMURA, TAKEMARO YAMAMOTO AND MASAE ARAI. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 237-56(1928); *Abstracts* 1, 19-22.—The sepn. of the Mg isotopes was tried with the following compds.: (a) $\text{MgCl}_2 \cdot 3\text{Mg}(\text{OH})_2 \cdot n\text{H}_2\text{O}$, (b) MgHCO_3 and (c) carnallite, $\text{MgCl}_2 \cdot \text{KCl} \cdot 6\text{H}_2\text{O}$. In case (a) no difference was detected in the at. wt. of Mg of the various fractions; (b) gave a 0.11 difference; (c) gave 0.15. The detn. of the at. wt. offered a probable error of 0.12.

A. L. H.

The spectrum of "nebulium." A criticism. ADOLFO T. WILLIAMS. *Contrib. estudio de las ciencias fis. y mat., La Plata* 4, 45-51(1926); *Chem. Zentr.* 1927, 1, 21.—It is shown that the conclusions reached by Lemon (*Nature* 113, 764(1924); *Phys. Rev.* [2], 23, 766(1924)) on a basis of purely empirical graphical representation are erroneous. According to W., the lines of nebulium correspond to definite states of ionization of known elements (cf. Rosseland, *C. A.* 19, 774), e. g., highly ionized He in a medium of low d.

C. C. DAVIS

The photographic plate in the service of the spectral analysis of the nucleus of the atom. F. KOHLRAUSCH. *Phot. Korr.* 62, 113-9(1926).—A simple explanation of the detn. of the frequency of γ -rays by means of the energy of the electrons they liberate from various substances. This energy is detd. from the so-called "magnetic spectra" of the electrons, which are recorded on a photographic plate by the impact of the electrons. γ -Rays necessarily have their origin in the nucleus of the atom.

M. W. S.

Extraction and recovery of radium, vanadium and uranium from carnotite. H. A. DOERNER. *Bur. of Mines, Rept. of Investigations*, No. 2873, 12 pp (1928).—A modification of the HNO_3 extraction process of the U. S. Bur. of Mines is proposed. The ore is first roasted. After grinding in a pebble mill and Na_2CO_3 leach the usual HNO_3 leach is given in counter-current equipment. A high recovery of all 3 elements is made.

L. D. ROBERTS

Recovery of radium from old luminous paints. I. YA. BASHILOV. *J. Chem. Ind. (Moscow)* 4, 425-7(1927); cf. *C. A.* 21, 2436.—Luminous paints consisting of ZnS which has been calcined at 1000-1300° for its transformation into a cryst. modification and of a very slight addn. (50-250 mg. per kg.) of Ra salt lose their luminosity in the course of time, but their Ra content remains practically unchanged and can be recovered. A method for the recovery of Ra from these paints has been given by A. Francis (cf. *C. A.* 16, 3030), but it is rather complicated and laborious. B. proposes a simple method which is based on the circumstance that the radioactive ingredient is disposed on the surface of ZnS and can be extd. by comparatively weak agents, which hardly affect the other elements. The scraped-off paint in powder-form is first calcined at low temp. to destroy the gum and then treated with dilute HCl. Ra dissolves, the soln. is concd. by evapn., a few mg. of BaCl_2 and a few vols. of concd. HCl are added and the ppt. of BaCl_2 is allowed to settle for several hrs., after which it is pressed out, washed with concd. HCl and dried to absence of HCl odor. An aq. soln. of this BaCl_2 ppt. which contains most of the Ra, can be used for activation of fresh ZnS . On account of the slight soly. of BaCl_2 in concd. HCl, part of this salt remains in soln. together with some Ra. The amt. of the latter which remains dissolved may reach up to 25%; it can be recovered after pptn. of BaCl_2 by evapn. the filtrate to dryness to remove HCl, dissolving in water and using the soln. for activation of ZnS . By this method B. easily extd. 73.5% of Ra contained in old luminous paints scraped off from dials used in aviation. The new Ra paint thus obtained possessed a high degree of luminosity.

BERNARD NELSON

The chemical composition of the uraninite of Karelien and its lead-uranium ratio. K. NENADKEVICH. *Acad. Sciences Leningrad. Bull. Acad. St. Petersburg* 1926, 767-74; *Chem. Zentr.* 1926, II, 3029.—Four samples of uraninite, which contains, besides U and Pb oxides, rare earths, Th oxide, Si, Ca and Cl, were analyzed to det. their Pb/U ratio. This ratio is evidently influenced by secondary chem. changes in the mineral; it was max. in one sample contg. 63.4% UO_2 but no UO_3 . In the best preserved sample the ratio was about 0.3, which indicates about 2×10^9

ys. for the age of this mineral. It was proved by at. wt. detns. (206.06) that the Pb originated by transformation of the U. The Pb was weighed partly as sulfate and partly as nitrate, a method to which attention is particularly called. C. C. DAVIS

The age of uranium minerals in pegmatite veins. A. FERSMAN. Acad. Sciences Leningrad. *Bull. Acad. St. Petersburg* 1926, 775-80; *Chem. Zentr.* 1926, II, 3029; cf. preceding abstr.—The detn. of the age of minerals by the Pb/U ratio can lead to erroneous conclusions, if the mineral has during its formation absorbed Pb salts from the magma, or if U compds. or Pb compds. are dissolved to different extents.

C. C. DAVIS

The yield on β recoil of thorium B. K. DONAT AND K. PHILIPP. *Naturwissenschaften* 16, 513(1928).—Recently (C. A. 22, 538) a recoil yield of 2 to 6.5% of the theoretical value was found for Th B on β emission. The explanatory assumption then made of evapn. of the recoil atoms from the receiving plate *in vacuo* was now tested by cooling the plate by liquid air. The yield was found to increase to 9 to 11% at -90° , to 33% at -170° . Contamination of the plate by active material was negligible. Apparently many atoms can during β emission overcome the surface forces holding them.

B. J. C. VAN DER HOEVEN

The visibility of β -scintillations. HANS PETTERSON AND GERHARD KIRSCH. *Naturwissenschaften* 16, 463(1928).—To the note of Bothe and Franz (cf. C. A. 22, 1902) on the results of scintillation count the authors reply that the effect of β scintillation on a ZnS screen is very small. Several reasons are advanced to support P.'s contentions.

B. J. C. VAN DER HOEVEN

The radioactivity of the water of Cluj and its origin. G. ATHANASIU. *Bull. sect. sci. acad. roumaine* 10, No. 6, 1-2; *Chem. Zentr.* 1927, I, 3182; cf. C. A. 22, 725.—The radioactivity of Cluj water is 1.11 millimicrocuries ($\pm 5\%$), and in all the tests the variation was not over 10%. The radioactivity is not confined to the Cluj springs, but is prevalent in the springs of the entire region. The springs of Magura-Marisel show the highest radioactivity of any yet measured in Roumania. The granite of the region is weakly radioactive and is probably the source of the radioactivity of the springs.

C. C. DAVIS

The radioactivity of the sediment of springs. G. NUSSBERGER. *Erweiterter Jahresber. Nahr. Ges. Graubündens Feier ihres 100-jähr. Bestehens, Neue Folge* 64, 1926; *Chem. Zentr.* 1927, I, 1813.—The sediments of the springs of Val Sinestra, Andeer, Val and Mauritius (St. Moritz) were examd. for their radioactivity. In the Grison schist region, the mineral springs are more radioactive than the fresh-water springs of the region.

C. C. DAVIS

Investigations of the radioactivity of some mineral waters and of the drinking water of the Somes and Cris valleys (Roumania). G. A. DIMA. *Bull. sect. sci. acad. roumaine* 10, No. 6, 21-9; *Chem. Zentr.* 1927, I, 3182.—Various springs were examd. with a view to detg. whether the radioactivity varies with the rate of flow at different times of the yr. It was found that the greater the flow the smaller was the radioactivity. The radioactivities varied between 0.1 and 12.85 millimicrocuries per l.

C. C. DAVIS

A possible explanation of the double sign of Hall's coefficient. VITO GIAMBALVO. *Nuovo cimento* [N. S.], 5, 41-52(1928).—G. has stated and tested the hypothesis that the concn. of free electrons in metals depends upon the magnetic field. The field produced by the primary current engenders a difference of potential that is in excess of that demanded by the usual electronic theory. The two differences of potential have opposite signs so that the double sign of the Hall effect should explain the prevalence of one or the other of two partial effects.

L. T. FAIRHALL

Observed relative intensities of the Stark components of $H\alpha$. J. STUART FOSTER AND M. LAURA CHALK. McGill Univ. *Nature* 121, 830-1(1928); cf. C. A. 21, 359.—New photographs of the Stark components of $H\alpha$ have been taken by the Lo Surdo method. A microphotometric record, which is reproduced, shows that the relative intensities agree with those calcd. by Schrödinger by the wave mechanics. They are not in agreement with the theoretical predictions of Kramers (correspondence principle) and Epstein (wave mechanics), or with the exptl. results of Stark by the canal-ray method.

F. A. JENKINS

Statistical experiments on the motion of electrons in gases. R. D'E. ATKINSON. *Proc. Roy. Soc. (London)* A119, 335-48(1928).—The interpretations given by Townsend for the results of his recent expts. on the cond. of gases are criticized, and an attempt is made to reconcile these results with the quantum theory. The low values obtained by T. for the ionization potential of He are due to the fact that metastable 2^1S He atoms ionize the mols. of impurity gases by collisions of the second kind. The

resulting ionization current would be independent of the amt. if impurities present over a considerable range. This explanation could be verified by positive-ray analysis of the ions produced. With Ne, ionization of the impurity mols. by the absorption of Ne radiation probably plays a large part. The exponential increase of the current at potentials above 60 volts may be accounted for partly by direct collisions of electrons with mols. of the impurities, but principally by the diffusion of the metastable atoms between the time of their formation and the collision of the second kind. The distance of this diffusion may be sufficient to bring the metastable atom to a point in the field at which the energy of the electron produced on collision may differ considerably from that of the original exciting electron. The quantum theory is not easily applied to such statistical high-pressure expts., but A. is able to show by an approx. calcn. that the results of T. are at least not in disagreement with the theory. No reliable estimate of the ionization potentials can be obtained from these expts. In discussing certain objections raised by T. to the results of direct electron impact expts., it is emphasized that the elastic collisions which occur in these expts. below the first crit. potential do not take place without loss of energy, but involve the definite, though small, loss required for conservation of momentum.

F. A. JENKINS

Theory of normal cathode fall in glow discharges. K. T. COMPTON AND P. M. MORSE. Princeton Univ. *Phys. Rev.* 30, 305-17(1927).—From the principle of min. energy dissipation it is shown that the actual potential distribution in the fall space must be that one which is most favorable to ionization, subject to limitations imposed by Poisson's equation. With the aid of this principle, taking as known quantities of the N cathode fall V_n and Townsend's ionization const. N and V_0 , expressions are derived for the potential distribution the thickness of the fall space d_n , the distribution of ionization n_z and the c. d. j_n , which agree with exptl. values. The most important results are given by the equations: $pd_n = 0.85 (V_n/NV_0)[1 + (V_0/0.97V_n) + \dots]$ and $j_n/p_2 = 1.85 (10)^{-4} (L/M)^{1/2} [(kN)^{1/2} V_n^{3/2}/(1 - (n_0/n_d))]$ in which L , M and p are the mol. mean free path, mol. wt. of positive ions and gas pressure. It appears that the N cathode fall is found when the potential is distributed in the manner most favorable to ionization, without restriction by space-charge considerations. When the c. d. exceeds the N value, space-charge considerations require a less favorable potential distribution and hence a larger cathode fall, which is the abnormal case.

BERNARD LEWIS

The interaction between radiation and electrons. ARTHUR H. COMPTON. Univ. of Chicago. *Phys. Rev.* 31, 59-65(1928).—The production of recoil electrons is an example of the action of radiation on free electrons, whereas the photoelec. effect with x-rays is an example of the action of radiation on a pair of positive and negative charges. In both effects expt indicates that the whole momentum absorbed from the radiation is imparted to the electron that is set in motion by the radiation, showing that the duration of the radiation is short compared with the natural period of the electron in the atom. It is assumed that the action is instantaneous. In contrast with the prediction of Lorentz's force equation, which would predict an impulse imparted to an isolated electron almost in the direction of the elec. vector, the expts. show that the preferred direction of motion of the recoil electrons is perpendicular to the elec. vector. An impulse on a free electron in the direction of the elec. vector would not be consistent with the conservation of momentum. The photoelectrons on the other hand have the elec. vector of the incident wave as their preferred direction of motion (neglecting radiation pressure), though the expts. show that the impulse imparted to the electron by the radiation may make a considerable angle with the elec. vector. In this case the conservation of linear momentum permits motion in any direction, since equal and opposite impulses are applied to the positive and negative parts of the atom by the elec. vector; but the conservation of the angular momentum of the system requires that the impulse shall be imparted in a direction detd. by the instantaneous position of the electron in the atom. Expts. are consistent with this requirement, but indicate that Lorentz's force equation is only statistically valid in defining the direction of the action of the elec. vector on the photoelectron.

BERNARD LEWIS

The free electron in the homogeneous magnetic field according to Dirac's theory. I. I. RABI. *Z. Physik* 49, 507-11(1928).—Highly mathematical. W. W. STIFLER

The electronic theory of metals. A. SOMMERFELD. *Naturwissenschaften* 16, 374-81(1928); cf. *C. A.* 22, 1538.—A review is given on the basis of the new quantum and electron theories of the present status of the metallic conduction theory. Contrary to classical statistical mechanics and due to a typical condition of the electron gas at ordinary temps. (Pauli restriction) the Fermi Dirac distribution law gives an av. electron velocity independent of temp.; it is related to the electron energy by $E_e = mv^2/2$

and is practically equal to the zero point energy. The electron waves are in the range of soft x-rays (λ of 10^{-8} cm.). The exit work of electrons from a metal W_e is due to electrostatic effects of the surrounding charges; it is usually higher, sometimes lower than W_i , the internal energy of the electron gas. By powerful elec. field the latter case can be realized. The Volta potential between 2 metals can be expressed by $eV_{12} (W_{e1} - W_{i1}) - (W_{e2} - W_{i2})$ on the basis of the assumption that thermal equil. is established between electrons in a narrow "Hohlraum" between the 2 metals. Actual soldered contacts need a different treatment. The "Hohlraum" disappears. Only the internal work functions det. the thermo-elec. effect. Cond. has been brought to a basis of dispersion of electron waves by the field of atoms and their mutual interference. From the free path analog of an electron is then found that $l = \text{const}$

$\frac{A^2 \theta v^2}{dII(c)\phi(x)}$, with $II(c) = \int_0^1 \frac{u^2 du}{(u+c)^2}$, $\phi(x) = \frac{1}{x^3} \int_0^x \frac{\xi d\xi}{(\xi^2 - 1)}$ for $c = \left(\frac{\lambda}{4\pi b}\right)^2$, $x = \frac{\theta}{T}$ in which A is the at. wt. of the metal ion, θ the Debye temp. for the lattice vibrations, v the electron speed, b the parameter detg. the decrease in d. of the electron atm. of the ions. The const. is equal to $\frac{k}{24\pi e^4 L^2}$. For multivalent ions z^2 has to be added in the

denominator. The temp. dependence of ρ , the sp. resistance, follows from $\phi(x)$; for $x < 1$ (high temp.) ρ is proportional to T , a significant result. For very low temps ρ appears to decrease proportionally to T^2/θ^3 in good agreement with exptl. data on Au (Grüneisen). Calcns. of the pressure influence on ρ also give results in agreement as far as the order of magnitude (10^{-17}) with expts.; likewise anisotropic conduction effects.

B. J. C. VAN DER HOEVEN

Theory of the electrical conductivity of metals. II. ST. PROCOPIU. *Bull. sect. sci. acad. roumaine* 10, 93-5(1926); *Chem. Zentr.* 1927, I, 859; cf. *C. A.* 21, 1746.--Objections to the theoretical basis of the Grüneisen equation ($\rho = KCT$) are discussed. It is concluded that as yet it has not been established on a sound theoretical basis.

C. C. DAVIS

The Saha theory and the conductivity of flames containing alkali metal vapors. H. A. WILSON. *Proc. Roy. Soc. (London)* A119, 1-11(1928).—A derivation of an equation for calcg. the equil. const. of the reaction $M = M_+ + e$ is given in which a certain fraction of the salt introduced into the flames is reduced to the metallic state and only a fraction of the carriers of the negative electricity consists of free electrons. Results show that at high temps. these fractions are near unity and are nearly const. at 2000° K. They are also nearly independent of concn. of the metal in the flame. Relative condns. from various sources agree well with Saha's theory.

R. H. L.

Gas absorption as influenced by the electric discharge; clean up and related phenomena. ERICH PIETSCH. *Ergebnisse der exakten Naturwissenschaften* 5, 54 pp. (1926); *Chem. Zentr.* 1927, I, 16-7.—P. gives a comprehensive crit. review of clean-up expts. in Geissler tubes, incandescent cathode tubes and incandescent lamps. In the case of Geissler tubes the question of absorption is discussed in its relation to cathode disintegration, cathode fall, cathode material and the glass wall; in x-ray tubes the phenomena of so-called high vacuum is discussed. In incandescent cathode tubes, the work of Campbell and his collaborators shows that absorption is associated with the lower limit of glow-potential. Glow-potential diminishes with increasing mol. wt. of the gas (investigated in the case of H_2 , CO, N_2 , P). The double role of Hg vapor is discussed at length. According to the mol.-wt. rule, Hg lowers the glow potential and thereby favors absorption, on the other hand with Hg. discharge is accompanied by the evolution of gas from the glass walls (counter-effect). The part played by the walls of the vessel in absorption remains in dispute. The present work does not point conclusively to a polarity between the walls of the vessel and the gas. Clean-up in incandescent cathode tubes is investigated, particularly in the case of the noble gases, O, N, H and CO. N and H show clean-up of their atomic modifications. According to Schwab and Pietsch, in the presence of small quantities of O (oxide cathode) water is formed, and this is then absorbed by PbO_2 , WO_3 , SiO_2 , Cr_2O_3 , I_2O_5 , P_2O_5 , H_2SO_4 and $FeCl_3$ to various extents. Increasing the water-vapor const. in the reaction chamber lowers this clean-up. The possibility of an absorption of atomic H is excluded by the inertness of the gas toward WO_3 , oleic acid and indigo- H_2SO_4 . Clean-up in incandescent lamps is of great technical interest as a means of rapid and effectual evacuation. P. strongly aids absorption, but the nature of this phenomenon is not clear. Certain salts (given in the original) show a similar effect. The reactions, investigated by Langmuir, occurring in incandescent lamps at low pressures and those reactions resulting in a decrease of pressure within the system are treated briefly. Typical reactions in,

clude the reaction between the charged gas and an incandescent wire (W and O_2 or Cl, and also C and O_2), the reaction between the gas and the vapor given off by the wire (W and N_2 or CO_2 , also Mo and N_2 , Pt and O_2), the reaction between an incandescent wire and the gas which has been changed because of the discharge, catalytic reactions. The meaning of these phenomena, which are not explainable through chem. reactions, is to be reached through a comprehensive theory of absorption when the problem is more systematically investigated and when the phenomena of absorption are distinguished from associated phenomena. C. C. DAVIS

Influence of anode heating on the ignition of metal arcs. H. ALTERTHUM AND H. EWEST. *Z. tech. Physik* 9, 221-3(1928).—By measurements on arc formation between two heated W spirals it was found that in 10^{-3} mm Hg vacuum the c. d.-voltage characteristics are independent of the anode temp. However, in 760 mm. N_2 the ignition potential for hot anode (1670°) was 120 v., for cold anode more than 220 v., in A + 20% N_2 at 50 and 141 v., resp. The influence is attributed to longer free paths of the electrons. Lower pressure reduces the potential from 90 v. at 760 mm. to 35 v. at 360 mm. The results, also including the influence of electrode distance, are represented in several graphs B. J. C. VAN DER HOEVEN

The ignition potential of a glow discharge. H. ALTHERTHUM, M. REGER AND R. SEELIGER. *Z. tech. Physik* 9, 161-72(1928).—A review. The elec "respiration" of vacuum tubes (diodes, 10^{-2} to 10^{-4} mm Hg), i. e., the appearance of anodic glow at 440 v, 10 milliamps. and subsequent disappearance, is due to small amts. of impurities in the hydrogen filling, particularly org. vapors (stopcock grease, etc.). For measurements of actual ignition potentials (point where potential begins to decrease with rising c. d.) the lamps were carefully heated at 350° in *vacuo* and the W filament degasified with 8 amps., the exptl. current being 6 amps. Characteristic *i*-V curves for several gases are shown, also curves of ignition potential as a function of pressure (up to 10 mm.) and of gas compn. (H_2 , A, Ne, N_2). With increasing pressure it has a min. between 0.1 and 1.0 mm. Hg below 100 v.; the same holds for H_2 - N_2 , H_2 -A and N_2 -A mixts. The min. is explained by competition between increasing no. of collisions and decreasing ion yield of the collisions; the magnitude of the potential is related to the mass of the positive ions; particularly at low pressures the potential increases with lower wt. Several other theoretical points are discussed B. J. C. VAN DER HOEVEN

Direction of photoelectron emission. DONALD H. LOUGHRIDGE. Calif. Inst. Tech. *Phys. Rev.* 30, 488-93(1927).—Photographs of the photoelectron tracks in a Wilson expansion chamber through which a narrow beam of monochromatic $M_{K\alpha}$ x-rays were passed were taken with a stereoscopic camera. The direction of the paths with respect to the x-ray beam was detd. from measurements made with a *pecially designed stereoscopic comparator*. 445 tracks were studied of which 231 were in A, 123 in air and 91 in H_2 . Curves showing the frequency of occurrence of different angles of ejection have a fairly sharp max. for angles of about 70° with the forward direction of the x-ray beam. The curves are similar for the 3 gases studied except that the max. in the case of H_2 is somewhat sharper than for the other 2 gases. B. L.

Demonstration of a new photoelectric effect. F. M. PENNING. *Physica* 8, 137-40 (1928).—Details are given of expts. on the effect recently described (cf. C. A. 22, 1536) of increase of the spark potential of a Ne-A tube (20 mm. Ne, 0.001 % A) on intensive radiation with light from another Ne tube. The theory of the effect is based on ionization by metastable atoms B. J. C. VAN DER HOEVEN

Safety standards of protection against x-ray dangers. A. MUTSCHELLER. *Radiology* 10, 468-74(1928).—Tolerance doses for radiation proposed by different investigators are correlated, and a safety tolerance dose of 0.01 of a skin erythema dose per month is recommended. The total thickness of Pb required for this degree of protection is not less than 2 mm. for radiography and fluoroscopy, not less than 3.25 for superficial therapy and not less than 5.6 for deep therapy. E. H. QUIMBY

Sources of error in precision wave-length measurements of x-rays and contribution to the determination of normal lines. H. IWATA. *Z. Physik* 49, 217-27(1927).—There is an important need of standard reference lines in x-ray spectroscopy to avoid the necessity of abs. measurements in each case. The Cu $K_{\alpha 1}$ line may be taken as a primary standard. It is possible to eliminate errors by working both with the Seemann wedge method and with the Bragg rotating-crystal method, since the sources of error in each of these methods is lacking in the other. The wedge method is unsuitable for rays of large glancing angle, and unevenness in the plate is a source of error. In the rotation method the sources of error are the divisions of the goniometer circles and imperfections of the crystal face. Comparison of the results obtained by the

two methods, therefore, yield accurate values. The W $L_{\alpha 1}$, W $L_{\beta 1}$, W $L_{\beta 2}$, Pb $L_{\alpha 1}$ and Mo $K_{\alpha 1}$ lines were detd. by both of these methods with the following results, the figure (in X-units) obtained by the wedge method being given first in each case: 1473.354, 1473.354; 1279.29, 1279.24; 1242.15, 1242.155; 1172.79, 1172.77; 708.05, 707.96. The W $L_{\alpha 1}$ and Mo $K_{\alpha 1}$ lines are proposed as secondary standards with the values 1473.35 and 708.05. The other precision detns. of these lines are recorded and a note calls attention to Siegbahn's latest detn. of the Cu $K_{\alpha 1}$ line (cf. *Physik. Ber.* 8, 2101 (1927)). The above figures are based on the older value, 1537.30. A. W. KENNEY

X-rays of long wave length from a ruled grating. FRANKLIN L. HUNT. Bur. of Standards. *Phys. Rev.* 30, 227-31(1927).—By the use of a grating ruled on glass (200 lines per mm.) at grazing incidence (20° to 40°) in vacuum, the following lines have been obtained: M_{α} of Pt (6 A. U.); K_{α} of Al (8.3 A. U.); L_{α} of Cu (13.3 A. U.); L_{α} of Fe (17.7 A. U.); L_{α} of Cr (21.5 A. U.); K_{α} of C (45.8 A. U.). A water-cooled metal x-ray tube with hot lime-coated Pt cathode was used. This was connected directly to the spectrometer with no absorbing film between the anticathode and the photographic plate. Wave lengths were detd. with reference to L_{α} of Cu and also directly by calcg. from the constns. of the spectrometer. BERNARD LEWIS

A new method of spectroscopy for faint x-radiations. P. A. ROSS. *J. Optical Soc. Am.* 16, 433-8(1928).—The difficulty of analysis of extremely faint x-rays by the crystal reflection method has led to the development of an analysis depending on absorption. Two foils of chemically pure Ag and Cd were stretched on small rectangular frames with adjustments for rotating the foils about a vertical axis so that the exact thickness to the x ray beam could be changed and so mounted that either or both foils could be placed in the beam. An ordinary ionization spectrometer was used to det. the transmission curves. After the foils had been adjusted to give the same absorption for a series of wave lengths, the crystal was removed and the ionization chamber swung into direct line with the slits, which were opened to several mm. Ionization current readings were then taken with the foils alternating in the path of the beam and their differences recorded as representing the intensity of the band of radiation between their K limits. In the case of Cd and Ag the width of this band was about 0.022 A. U. and for Pb-Bi about 0.0037 A. U. with mean values of 0.474 A. U. and 0.1383 A. U. The intensity was nearly uniform across the band and its purity was independent of the width of the slits over a wide range. Other elements can be used as foils, and it is possible to use screens in which salts are the absorbing media. It is calcd. that, allowing for the wider slits which may be used in this method without decrease of resolving power, the advantage in efficiency over the crystal reflection method may be over 1000-fold. A. W. KENNEY

Thermoluminescence excited by x-rays. Further experiments upon synthetically prepared materials. FRANCES G. WICK AND MABEL K. SLATTERY. *J. Optical Soc. Am.* 16, 398-408(1928); cf. *C. A.* 22, 1103.—The thermoluminescence excited by x-rays in the sulfates of Cd, Na and Zn contg. slight amts. of Mn is the object of this study. The sulfates were prepd. by adding to the metal sulfates $MnCl_2$ soln. with a small amt. of H_2SO_4 , using about 1 mol. Mn to 250 mols. of the salts except that in the case of Cd the ratio was 1 to 900 of Cd. Samples were evapd. to dryness, ignited to drive off fumes, sifted and exposed for 1 hr. to x-rays from a Mo tube running on 50 kv. and 3 milliamp. at 11 cm. from the tube. Immediately after exposure the material was put into long glass tubes immersed in liquid air. The thermoluminescence was excited by heating the specimens on a Cu plate fastened to a small elec. stove, the temp. of the plate being measured by a thermocouple. Photometric detns. of the thermoluminescence were then made. At liquid air temp., the thermoluminescent property is apparently preserved indefinitely, and there is no phosphorescence, although all samples were phosphorescent at room temp. after exposure to x-rays. In every case it was found that the specimen exhibited two maxima of thermoluminescence. One is produced very soon after the heating is commenced and lasts but a short time; the other comes up much less quickly and persists longer. In some specimens the 2 emissions were of different colors. If the material stands at room temp. after exposure to x-rays, the first effect lasts only a few hrs. while the second may last for months or even yrs. At liquid-air temp. both effects are preserved. The decay curves were plotted to show the effect of the temp. on thermoluminescence, which is to heighten the max. intensity and shorten the time. The effect of higher temp. of exposure to x-rays is to decrease the intensity of the max. and lengthen the decay. The effect of an increased voltage on the x-ray tube is to heighten the max. intensity and shorten the life. The thermoluminescence of all the specimens can be quenched by exposing them to sunlight or particularly to ultra-violet light. In all cases also the color of

light which exactly matches the thermoluminescence is effective in quenching. In some cases the samples after exposure to x-rays fluoresce in ultra-violet when they did not previously.

A. W. KENNEY

Regularities in physical and chemical action of x-rays. R. GLOCKER. *Z. tech. Physik* 9, 201-7(1928).—A review with 35 references dealing with ionizational effect, photographic action, fluorescence excitation, action on Se cells and photochem. actions of x-rays.

B. J. C. VAN DER HORVEN

Application of x-ray crystal analysis to the problems of chemistry. G. SHEARER. *J. Oil Colour Chem. Assoc.* 11, 75-89(1928).—The way in which x-ray crystal analysis has been applied to some chem. problems is outlined. Its possible application to the paint-varnish industry is discussed.

R. J. M.

Three notes on the quantum theory of aperiodic effects. J. R. OPPENHEIMER. Harvard Univ. *Phys. Rev.* 31, 66-81(1928).—In section 1 it is shown that the normalization of the characteristic functions corresponding to a continuous spectrum, which has been introduced by Hellinger and Weyl, satisfies the requirements of the δ -normalization of the Dirac-Jordan transformation theory. It is further shown that this normalization makes the flux to and from infinity of systems for which an integral of motion β lies in the little range $\Delta\beta'$ equal to $(\partial E/\partial\beta')\Delta\beta'$. In section 2 the condition for the validity of classical mechanics in the form $\text{grad } \lambda \ll 1$, where λ is the instantaneous wave length $\lambda = (h/2\pi)[2M(E - U)]^{-1/2}$, is applied to establish Rutherford's formula for the scattering of α -particles. In section 3 a method is developed for computing the transition probabilities between states of the same energy which are represented by almost orthogonal "eigenfunctions." The theory is applied to the ionization of H atoms in a const. elec. field. The period of ionization in a field of 1 v per cm. is 10^{10} sec. The bearing of such transitions on the problem of metallic conduction is discussed.

BERNARD LEWIS

The application of the irregular doublet law to complex spectra. K. MAJUMDAR AND G. R. TOSHNIWAL. Univ. of Allahabad. *Nature* 121, 828-9(1928).—Several terms are identified in the K^+ and Ca^{++} spectra by the use of the irregular doublet law. The application of the law to the isoelectronic systems (I) A, K^+ , Ca^{++} , Sc^{+++} (II) K, Ca^+ , Sc^{++} , T^{+++} is illustrated by a table. The ionization potential of Ca^{++} is approx. 52 v. The high excitation energy of certain Ca^{++} lines is against the view that they appear in the solar corona.

F. A. JENKINS

Possible meaning of the additional potential of 1.4 volts in the mercury atom. ADOLFO T. WILLIAMS AND RAMÓN G. LOYARTE. *Contrib. estudio de las ciencias fis. y mat., La Plata* 4, 35-44(1926); *Chem. Zentr.* 1927, I, 232.—The potentials measured by Franck and Einsporn (cf. *C. A.* 14, 3360) and by Loyarte (*Contrib. estudio de las ciencias fis. y mat. La Plata* 4, 7(1926); cf. *C. A.* 21, 1501), which correspond to no known lines or end series of the Hg atom, can be explained by assuming an abnormal arc spectrum for Hg with a potential of 21.59 v. The ratio of this potential to that of the normal spectrum (10.39 v.) would be 2.07, which is identical with the corresponding ratio of the known spectra of Tl.

C. C. DAVIS

The addition spectral series of Hicks. ADOLFO T. WILLIAMS. *Contrib. estudio de las ciencias fis. y mat., La Plata* 3, 451-87; *Chem. Zentr.* 1926, II, 3018.—The wave lengths of the inverse series for the spectra of various metals were calcd. and compared with exptl. data. It is concluded that no phys. significance can be attached to the inverse series, and that the case is one of coincidence of numerical values.

C. C. D.

The mechanism of the emission of addition spectral series. ADOLFO T. WILLIAMS. *Contrib. estudio ciencias fis. y mat., La Plata* 1927, 115-24; *Chem. Zentr.* 1927, II, 15.—The new hypothesis of Hicks (*C. A.* 20, 2948) according to which the emission of addn. series is caused by the simultaneous neutralization of doubly ionized atoms appears to W. to be untenable. It is doubted whether these series can be realized experimentally.

C. C. DAVIS

Spectroscopic study of the after-glow of nitrogen. GERHARD HERZBERG. *Z. Physik* 49, 512-33(1928); cf. *C. A.* 22, 1911.—Characteristics of the type of discharge which brings out the after-glow of N are: (1) the excitation of the red and infra-red arc lines; (2) the appearance with considerable intensity of the second positive group of bands (and eventually the fourth positive group); (3) the enhancement in these bands of members with large values of n' . The existence of N atoms is thus necessary for the appearance of the after-glow. Its spectrum consists of bands which have been identified with the first positive group of N. At the temp. of liquid air the intensity max. in the green, yellow and red after-glow bands is displaced toward the violet; but with increasing pressure of the gas in the discharge tube, and with increasing time

between the instants of excitation and observation, the intensity max. shifts toward the red. In addn. to these, the CN bands at 4216 and 3883 Å. U. appear faintly but with modified appearance in the after-glow. Their behavior is regarded as a resonance fluorescence similar to that observed by Wood for I. It is pointed out that the majority of observed facts of the after-glow support Sponer's theory of its production (*C. A.* 20, 1355).

C. C. KIESS

The inverse Stark effect of the second and third members of the principal series of sodium. W. GROTRIAN. *Z. Physik* 49, 541-5(1928).—The Stark effects for the Na doublets at 3303 Å. U. and 2853 Å. U. were measured in the second order of a concave grating for fields of various strengths. The observed displacements were toward the violet and were proportional to the square of the field. For fields of 100,000 v./cm. the shifts amounted to 0.02 Å. U. and 0.21 Å. U. resp. for the second and third series members, being a little greater in each case for the shorter component of each doublet.

C. C. KIESS

Active nitrogen. P. K. KICHLU AND D. P. ACHARYA. *Nature* 121, 982-3(1928); cf. *C. A.* 21, 1588. A new band system in the spectrum of active nitrogen, extending from 5500 Å. U. to 8900 Å. U., has been photographed after an exposure of 42 hrs. These bands originate from the N₂ mol.; which conclusion does not support Sponer's theory that active nitrogen is a single mol. of N. The agreement of the cause of these bands with the opinions of other authorities is pointed out. The recent conclusions of McLennan, Ruedy and Anderson ascribing the activity of nitrogen to chemiluminescence does not seem to be justified.

G. L. CLARK

Activation of hydrogen by electric discharge. G. A. ELLIOTT. *Nature* 121, 985 (1928). cf. *C. A.* 21, 1221.—Recent experimenters have been unable to activate hydrogen in an elec. discharge by the methods usually described. E. J. B. Willey is the only recent experimenter who has been able to obtain active hydrogen in a discharge tube. More details of Willey's procedure will be appreciated.

G. L. CLARK

Investigation of the negative band spectrum of nitrogen. L. S. ORNSTEIN AND W. R. VAN WIJK. *Z. Physik* 49, 315-22(1928).—Intensity measurements of the negative bands of N₂ at 3014 Å. U., 4278 Å. U., 3884 Å. U., and 4237 Å. U. shows that the statistical wt. of the terms with odd rotational quantum nos. is double that of terms with even quantum nos. The total energies of the bands were found to be in the ratios 52.12 : 2.7 : 1 in the order named.

C. C. KIESS

The bands of the third positive group of nitrogen. R. SCHMID. *Z. Physik* 49, 428-62(1928). The work of Guillery (*C. A.* 21, 1931) on the classification of the bands of the third positive group of N is here extended to include the bands (0,0) at 2260 Å. U., (0,1) at 2368 Å. U., (1,0) at 2154 Å. U., (1,1) at 2244 Å. U., (2,3) at 2316 Å. U., and (3,4) at 2289 Å. U. The new wave length data on which the investigation is based were obtained with a large quartz spectrograph. The details of the study are fully tabulated including calc'd. values for the moments of inertia and the inter-nuclear distances of the mol. in the various energy states.

C. C. KIESS

Infra-red absorption by the S-H bond. JOSEPH W. ELLIS. *J. Am. Chem. Soc.* 50, 2113-8(1928). The absorption spectra of ethyl, *n*-propyl, *n*-butyl, isoamyl, phenyl and benzyl mercaptans were exam'd. for bands which are characteristic of the S-H linkage. Assuming that the band at 3.8-3.9 μ represents a fundamental frequency of the S-H atom pair, search was made for harmonics of this band. A band at 1.99-2.00 μ was found to be a distinguishing feature in the spectra of the mercaptans and is regarded as the first harmonic of the fundamental. A table contains a list of the bands characteristic of mercaptans and sulfides.

C. C. KIESS

The absorption spectrum of thallium vapor between 7000 and 1850 Å. U. RAMÓN G. LOYARTE AND ADOLFO T. WILLIAMS. *J. phys. radium* 9, 121-6(1928).—Quartz-prism spectrographs were used to exam the absorption of Tl vapor in quartz tubes and bulbs which were maintained at temps. of 700° and 900°. The lines absorbed were those of the series $2^2P - m^2S$ and $2^2P - m^2D$. In the region 3225 to 3246 Å. U. four band heads, already noted by others and attributed to Tl₂, were observed.

C. C. KIESS

Investigations of the hydrogen lines in the electric arc. (Mlle.) M. HANOT. *Compt. rend.* 186, 1716-7(1928).—The arc between Cu electrodes in an atm. of H₂ is of very short duration, being first rectilinear, then bending and spreading in the direction of the magnetic field (used to separate the electrodes) before going out. The H lines observed in the rectilinear phase of the arc are very broad, H β being reversed, the width of the lines increasing with the current. Observed in the deviated phase of the arc, however, the lines are narrow, which is attributed to the fact that the current is

distributed over a wider area than in the rectilinear phase, with consequent diminution of the inter-mol. field.

Continuous and band spectra of zinc vapor. H. VOLKRINGER. *Compt. rend.* **186**, 1717-9(1928).—A heated quartz tube contg. Zn vapor was excited by means of the oscillatory electrodeless discharge. At low vapor densities the light emitted is continuous but of varying intensity, and extends from a point between 4000 and 4600 Å. U. into the ultra-violet near 2000 Å. U. Superposed on the continuous spectrum appear faintly the lines of the arc and spark spectra which fade away with increasing vapor density. For high vapor densities a complex band spectrum appears, extending from 4800 to 2975 Å. U. followed by a continuous band with max. at 2570 Å. U. The low-density phenomenon is attributed to the fall of free electrons with all initial velocities into various atomic orbits; the high-density phenomenon to the energy changes occurring among the various associations of atoms.

C. C. KIESS

The structure of the yellow sodium lines (5890, 5896). H. SCHÜLLER. *Naturwissenschaften* **16**, 512-3(1928).—S. succeeded in constructing a novel hollow cathode (cf. *C. A.* **20**, 2121; **22**, 912) for observation of the luminescence of metal vapors at low temps. The discharge is carried by 2 mm. A vapor. The tube is made of metal and cooled in liquid air. By reason of the considerable decrease in Doppler effect of the spectral lines great improvement in sharpness is obtained. Study of the 5890 and 5896 Na lines showed both of these to consist of at least 2 components: 5890 with $\Delta\lambda = 0.02$ Å. U., intensity ratio 1.25; 5896 with $\Delta\lambda = 0.023$ Å. U., ratio 1:2.0; in both cases the weaker component was on the violet side. The analysis was done by a Perot Fabry étalon of 8.3-mm. plate distance. Photographs of the lines in emission and absorption are shown. Increase in discharge current makes the components unite; further increase gives self-reversal followed by absorption. No explanation can as yet be given; nucleus action in analogy to the Li^+ fine structure (5485) is suggested.

C. C. KIESS

B. J. C. VAN DER HOEVEN

Absorption by quartz and by air and the components up to 1810 Å. U. ADOLFO T. WILLIAMS. *Contrib. estudio ciencias fis. y mat., La Plata* **1927**, 95-112; *Chem. Zentr.* **1927**, II, 138.—It is shown that with quartz spectrographs, photographs can be made up to 1838.30 Å. U. in air, and up to 1808.40 Å. U. (perhaps further to 1760 Å. U.) in N. By using fluorite, these limits can probably be extended.

C. C. DAVIS

Phosphorescence as related to electrical effects. R. W. POIN. *Naturwissenschaften* **16**, 477-84(1928).—A lecture on luminescence. The theory of luminescence as due to liberation of photoelectrons from the "phosphor" body and subsequent re-union with the remnants of the latter is exposed and many elec. expts. are described to substantiate it. The photoelec. cond. of insulating crystals follows for weak fields (non-satn.) Ohm's law with a resistance about proportional to T . From optical examn. of transparent phosphors, e. g., KCl or NaCl with traces of TiCl or PbCl₂ (strongly refractive addns.), it appeared that the absorption spectrum was substantially the same as that of extremely thin films (10^{-5} mm.) pressed between quartz of the pure admixt., TiCl or PbCl₂. This absorption is the active agent in electron liberation. A phosphor is defined as a mixed crystal with extremely small amts. of the one strongly absorbing component.

B. J. C. VAN DER HOEVEN

Resonance fluorescence of cyanogen. GERHARD HEKZBERG. *Naturwissenschaften* **16**, 464-5(1928).—During the after-glow of N₂ the violet CN bands usually appear with peculiar intensity distribution. In electrodeless ring discharges the distribution is quite different (only lines from 0-1 and 0-0 bands). It is assumed that this phenomenon is a resonance fluorescence similar to that of I and is excited by ultra-violet bands which are probably present in the after-glow of N₂. It would indicate that the final condition of the violet CN bands is not the ground level.

B. J. C. VAN DER HOEVEN

Photochemical cleavage of an iron carbonyl compound; the photochemical equivalence law. OTTO WARBURG AND ERWIN NEGELEIN. *Naturwissenschaften* **16**, 387(1928).—From irradiation expts. in 6 spectral ranges of complex iron (ferrocysteine)-CO compds. the photochem. equivalence law was confirmed, i. e., 4 mols. CO per quantum light. The photochem. effect W in thin layers was found proportional to $\alpha i \lambda$ (α abs. coeff., $i \lambda$ quantum intensity). From W and i measured for different λ values the absorption spectrum can thus be detd. A curve is given of $\alpha/\lambda_{\text{abs}}$ as a function of λ for the compds. examd.

B. J. C. VAN DER HOEVEN

The luminescence of formation of iodine. V. KONDRATEV AND A. LIPINSKII. *Naturwissenschaften* **16**, 463-4(1928).—The yellow luminescence of I₂ on heating at 600° to 700° appears in air or in a closed evacuated vessel. Its character (absorption by I₂ vapor) indicates its origin from the I₂ mol. The bands are sharp in yellow and

red. The green bands are diffuse. At shorter λ no bands are distinguishable. The presence of light $< \lambda 4995$ (convergence) seems to show that it is caused by a $I_{\text{res.}} + I = I_2 + h\nu$ reformation after heat dissoen.

4—ELECTROCHEMISTRY

COLIN G. FINK

The chemist in the electrical industry. G. S. PARLOUR AND C. H. CROWE. Can. Gen. Elec. Co. *Can. Chem. Met.* 12, 224-6(1928). E. H.

High-power electric furnaces for the manufacture of calcium carbide and of ferro alloys. (The Miguet furnace.) P. BERGEON. *Rev. Gen. Elec.* 22, 797-802(1927); *Science Abstracts* 31B, 68; cf. C. A. 20, 3392; 22, 916-7.—B., after describing the advantages which are offered by highpower elec. furnaces, both from the economic standpoint as well as from that of their regularity of function, passes on to describe the monophase furnaces of this type designed by Miguet. The special feature of the Miguet furnaces, which have been constructed up to a size of 6000 kw. is that they possess one single electrode which is fixed vertically, while the sole or hearth electrode is movable. This design has enabled Miguet to overcome many of the structural difficulties that arise when many electrodes are employed, in order to obtain a furnace consuming such large amts. of power, and it has also solved the complications offered by the current conductors. The problem of charging these large furnaces has only been solved after close study of all the conditions, and the soln. has been found in a system of mechanically controlled hoppers which discharge their contents in a few seconds into the furnace as and when required. In order to enable these monophase furnaces to operate with three-phase current, the system of distribution suggested by Scott for use with two furnaces on a three-phase system is recommended, and the installations are described of the Miguet furnace at the works of the Soc. Électrométallurgique de Montricher and at the works at St. Julien-de-Maurienne, the former for 6000 kw. and the latter for 5000 kw. The article is illustrated. H. G.

The hardness of electrodeposited nickel. D. J. MACNAUGHTAN AND A. W. HOTHERSALL. *Trans. Faraday Soc.* 24, 387-400(1927).—An attempt was made to develop practical methods of detg. hardness and stress in deposits and to ascertain the value of such tests for the control of conditions of deposition for the production of deposits for specific purposes. Exptl. data are given on the production of Ni deposits under carefully controlled conditions of bath compn., temp., purity of anodes, etc., and subsequent testing of deposits. Scratch, Brinell and scleroscope tests were made and stress was measured by depositing the Ni on one side only of a hardened and tempered steel strip and noting the bend. Details are given on the influence of temp., the prepn. of NiSO_4 , and of Ni anodes of high purities, compn. of electrolytes and the deposition expts. The effects of addns. of NaF , Na_2SO_4 , $(\text{NH}_4)_2\text{SO}_4$, the prevention of pptn. of basic salts in the deposit, and the production of hard deposits are discussed. Brinell hardness tests were made with 1-mm. balls and 10-kg. load, and an approx. method for rapidly ascertaining relative stresses is described. The presence of fluorides in the soln. results in low anode and cathode efficiencies, and the solns. contg. large amts. of Na_2SO_4 yield highly stressed deposits. Much harder deposits were obtained in baths contg. $(\text{NH}_4)_2\text{SO}_4$ than those contg. H_2BO_3 . W. H. BOYNTON

The mechanism of the action in galvanic baths. J. HAUSEN. *Metallborse* 18, 257-8, 314-5, 483-4(1928).—The modern views regarding throwing power are discussed. Expts. on Cu, Ni, Zn and Cr solns. show the effect of various factors on the throwing power of the respective soln. J. BALOZIAN

Electrodeposition of chromium. J. G. ROBERTS. *Roy. Tech. Coll. Met. Club J.* 1927-8, No. 6, 19-22.—The history of the development and some details of com. Cr plating are briefly outlined. DOWNS SCHAFF

Influence of the cathode on the electrodeposition of chromium. HIRAM S. LUKENS. *Metal Ind.* (N. Y.) 26, 354-5(1928).—See C. A. 22, 1283. E. H.

The effect of colloids in the electrodeposition of silver from silver nitrate solutions. S. WIERNICK. *Trans. Faraday Soc.* 24, 361-6(1928).—Detns. of "silver numbers" of numerous colloids (after the order of "gold numbers") used to reduce grain-size show that, with the exception of dextrin, there appears to be a rough relationship between the reciprocal Ag no. and the no. of crystals per sq. cm. Dextrin is much more effective in reducing the grain-size than would be expected from its Ag no. It appears to improve its protective capacity on standing. β -Naphthol and dextrose, possessing no protective action on the Ag colloid, show a corresponding inability to reduce the crystal size. The Ag nos. were detd. by the pptn. method of Zsigniondy. AgNO_3 cannot be used as a precipitant for all colloids but other precipitants were found that had approx. the same effect. A min. strength of precipitant is necessary to effect pptn. The relationship of Ag no. to grain-size is not marked, but enables the differentiation of "good" colloids from "bad." Calcd. Ag nos. for 13 protective colloids and reports of appearance of deposit and no. of crystals per sq. cm. are tabulated. W. H. B.

Removal of salts from water by electroösmosis. KURT ILLIG. Siemens-Halske, Berlin. *Siemens Z.* 8, 349-58(1921), cf. C. A. 21, 208.—By means of a three-compartment electrolytic cell a method has been devised for removing salts from water by taking advantage of the differential migration of ions under the influence of the elec. current. The ions will migrate to their respective electrodes from the middle compartment, producing in this section of the cell water of as good a grade as distd. water. The time required depends on Coulomb's law and the current density used. The best anodes are of magnetite with Fe, Zn or Sn cathodes. The activity of the diaphragm depends on the no. and size of the pores and its elec. resistance. Diaphragms of different materials are required to sep. the anolyte and the catholyte, resp., from the middle compartment. The catholyte will probably become predominately alk. and the anolyte acid in reaction as the electrolysis proceeds. Animal and vegetable membranes are best. A battery of several cells (three compartments each) in series is required for the best results, because the diaphragms do not have uniform values for solns. of all concns. of salts. The water is siphoned from the middle section of one cell to the middle section of the next as the salt concn. changes. The first 4 cells require 25 v.; then 3 vol. cells at 35 v.; 2 at 55 volts and 1 at 110 v. These make an efficient battery of 10 cells from the last of which the purest water is drawn. Power costs show this method to be from $\frac{1}{4}$ to $\frac{1}{5}$ of the cost by other purification methods. However, the method can scarcely compare economically with waste-steam methods, but should be very good for small-scale work where only a few liters an hour are required. C. J. BROCKMAN

Solid cells, in particular thermoelements of solid electrolytes. HERMANN REINHOLD. *Z. anorg. allgem. Chem.* 171, 181-230(1928).—Thermal e. m. f. is considered as a complex quantity which can be resolved into a homogeneous (Thomson) and a heterogeneous (Peltier) thermoelectric effect. The e. m. f. of the following solid cells was measured in the temp. range of 150° to 500° : (1) *Solid electrolytic thermoelec. elements*, $\text{Ag} | \text{AgI} | \text{Ag}$; $\text{Ag} | \text{AgCl} | \text{Ag}$; $\text{Ag} | \text{AgBr} | \text{Ag}$; $\text{Pb} | \text{PbCl}_2 | \text{Pb}$; $\text{Cl}_2 | \text{AgCl} | \text{Cl}_2$; $\text{Br}_2 | \text{AgBr} | \text{Br}_2$; $\text{Cl}_2 | \text{PbCl}_2 | \text{Cl}_2$. (2) *Solid isothermal galvanic cells*, $\text{Ag} | \text{AgCl} | \text{Cl}_2$; $\text{Ag} | \text{AgBr} | \text{Br}_2$; $\text{Pb} | \text{PbCl}_2 | \text{Cl}_2$; $\text{Pb} | \text{PbCl}_2 | \text{AgCl} | \text{Ag}$. The temp. coeff. of e. m. f. of cells of the type $\text{M} | \text{MX} | \text{X}_2$ can be calcd. from the thermoelec. e. m. f. of the cells $\text{M} | \text{MX} | \text{M}$ and $\text{X}_2 | \text{MX} | \text{X}_2$. The e. m. f. of the cell $\text{Pb} | \text{PbCl}_2 | \text{AgCl} | \text{Ag}$ can be calcd. from the measured e. m. f. of the cells $\text{Ag} | \text{AgCl} | \text{Cl}_2$ and $\text{Pb} | \text{PbCl}_2 | \text{Cl}_2$. The Nernst heat theorem is shown to be valid for these systems. Numerous exptl. results are tabulated. EDGAR R. SMITH

Electrolytic cell for producing caustic soda, chlorine, hydrogen, etc. JESSUP & MOORE PAPER CO. Brit. 281,184, June 2, 1926. Structural features.

Electrolytic refining of aluminum. ALUMINIUM-INDUSTRIE A.-G. Brit. 280,881, Nov. 22, 1926. The electrolyte comprises halide salts of Al and alkali or alk. earth metals which are molten at the working temp. at which the electrodes remain solid. Fe, Mn, Pb, Cd and Ni or their salts or oxides 0.1-0.5% may be added, as may also NH_4Cl . Cf. C. A. 22, 1737.

Active oxygen compounds. I. G. FARBENIND. A.-G. Fr. 633,360, Apr. 26, 1927. In the electrolytic prepn. of compds. contg. active O, the two electrodes are used simultaneously for this purpose; thus, if a soln. of $(\text{NH}_4)_2\text{SO}_4$ with H_2SO_4 is placed in the anode chamber, and 0.5% H_2SO_4 in the cathode chamber, $(\text{NH}_4)_2\text{S}_2\text{O}_8$ and H_2O_2 are obtained.

Beryllium. KEMET LABS. CO., INC. Fr. 633,491, Apr. 27, 1927. Be is prepd. by electrolysis of its anhydrous chloride in a bath of fused NaCl or halogen salts of other metals more electropositive than Be.

Diaphragms. THE GRAMOPHONE COMPANY, LTD. Fr. 632,679, Apr. 12, 1927. Metallic diaphragms, specially for gramophones, are formed by electrodeposition of Cu or Ni on a Ni cathode which has been dipped in $\text{K}_2\text{Cr}_2\text{O}_7$. A Mg salt may be added to the electrolytic bath.

Accumulators. CHARLES J. V. FÉRY. Fr. 633,179, Aug. 12, 1926. Accumulators are provided with a cover which allows the escape of gas, but excludes air.

Electric accumulators. COMPAGNIE GÉNÉRALE D'ÉLECTRICITÉ. Fr. 633,211, Apr. 14, 1927. IHCN or one of its salts is added to the alk. electrolyte of an accumulator contg. as the active mass, oxygenated compds. of Ni, to counteract the lowering of the capacity of the positive electrode.

Electric accumulators. PARISINO PETTINELLI. Fr. 633,006, Apr. 20, 1927. The plates of an accumulator are made of undulating strips of lead on which is a paste of active matter such as minium and an absorbent powder such as vegetable charcoal and an agglomerant.

Electric furnace. LE NICKEL. Fr. 632,366, July 21, 1926. An elec. furnace in which the tension reaches 200 v. per arc has a lining of chromite bricks. When used for metals a thick coating of slag is maintained at the bottom of the furnace to absorb a part of the voltage.

Electric induction furnace operating in a vacuum. N. R. DAVIS and METROPOLITAN-VICKERS ELECTRICAL CO., LTD. Brit. 281,379, Aug. 31, 1926. A furnace is described which is suitable for melting Pt, Cu, Cr, Pb, Sn, Zn, Ni, Fe and other metals or alloys. The furnace also may be adapted for use in distn.

Electric heating apparatus with means for automatically regulating the temperature. ANDRÉ BERGÉS. Fr. 632,301, Apr. 6, 1927.

Precipitation of dust from smoke. COMPAGNIE DES MINES D'OSTRICOURT. Fr. 632,185, Apr. 4, 1927. In an app. for the elec. deposition of dust from smoke the ionizers and precipitators are combined to form compd. electrodes.

Electric lamps. SOCIÉTÉ DU FILM EN COULEURS KELLER DORIAN and GEORGES CABET. Fr. 632,234, July 15, 1926. A lamp is described contg. gas under pressure which gives an intensive light for photographic, etc., purposes.

Electric lighting tubes. DEUTSCHE LEUCHTRÖHREN-GESELLSCHAFT. M.B.H. Fr. 632,704, Apr. 13, 1927. Elec. lighting tubes contg. rare gas and mercury vapors have 60 to 75% of Ne and 40-25% of Ar.

Electrical resistances. NAAMLOOZE VENNOOTSCHAP MACHINERIEËN EN APPARATEN FABRIEKEN. Fr. 633,579, April 29, 1927. See Brit. 270,677 (C. A. 22, 1549).

5—PHOTOGRAPHY

C. R. K. MEES

Preservation of photographic materials. Report of Committee. *Phot. J.* **67**, 498-9; *Nature* **120**, 891; *Brit. J. Phot.* **74**, 668-9 (1927).—To preserve negatives and positives as much as possible it is recommended that those on glass be hardened in chrome alum, fixed, washed and lacquered after drying. Film negatives should be copied upon glass because of the tendency of either nitrate or acetate bases to decay. Prints should be S-toned and varnished with a soln. of gum dammar in benzene. The article points out that the Pt process is not referred to in spite of its well known permanency.

G. E. MATTHEWS

Photographic density. J. C. VAN SELMS. *Dissertation, Utrecht, 1927*.—The extinction of a photographic plate is in general independent of the wave length for ordinary development. With plates strongly exposed and developed for a very short time, the extinction increases with decreasing wave length. A method is described for measuring in an abs. manner the intensity of light scattered at all angles by a photographic d. Measurements with blue and with red light showed that the intensity of light scattered at different angles is independent of the wave length. The intensity of scattered light was small at big angles, and very high at small angles, but no relation could be deduced between intensity and angle. A curve is given showing the intensity of the scattered light at different angles as a function of the plate extinction. The intensity of light scattered at a given angle is in certain cases independent of the extinction of the plate. The surface of the plate plays only a small part in detg. the scatter. The effect of diffraction round the silver grains was examd. on the basis of Rayleigh's law, but the exptl. results did not agree with the theoretical. The theory of Mie would probably be more applicable. The intensity of the scattered light could be explained if the variation of the n of the gelatin in the neighborhood of the silver grain were known.

B. C. A.

Mechanism of formation of the latent photographic image. F. C. TOY. *Nature* **121**, 865 (1928).—Recent exptl. work supports the prediction that the sensitivity—wave length and photo conductivity—wave length curves for pure AgBr emulsions will coincide when the thickness of the emulsion is of the order of 1.5μ . Results on an emulsion of 20μ thickness show that in all probability the phenomena of the primary stage of the formation of the latent image are closely related to those which cause the changes of cond. on illumination.

G. E. CHAMBERS

Image destruction by desensitizers. LUPO CRAMER. *Z. wiss. Phot.* **25**, 282-7 (1928).—Investigations on the influence of different kinds of red light used in dark rooms on highly sensitive plates treated with the following desensitizers: phenosafranine, pinakryptol green and pinakryptol yellow, especially in relation to the Herschel effect.

A. P. H. TRIVELLI

Aging phenomena of sensitized material. A. FUNGER. *Phot. Ind.* **25**, 1203-4 (1927).—The deterioration of plates and films, especially plates, on long keeping before use, takes the form principally of edge fog, general fog, and spots caused by bacterial action. F. states Homolka's explanation of edge fog as a consequence of a migration of traces of free sol. bromide from the edges towards the center of the plate during the earlier stages of the drying of the emulsion. The general (central) fog appears later. The danger of bacterial spots, although it can be minimized by suitable conditions of storage, is inseparable from the use of gelatin.

E. R. BULLOCK

Chemical sensitization of silver iodide gelatin plates. H. PRIESER. *Phot. Ind.* **25**, 520-1 (1927).—Using a pure iodide gelatin emulsion, prepd. with NH_3 and excess of sol. iodide and which had been allowed to set on glass plates before being washed and dried, F. treats strips with soln. of several inorg. and org. substances, and tabulates the effect on sensitivity for chem. and physical development and for printing out. A remarkable diminution of sensitivity is produced by hydrazine and thiocarbamide.

E. R. BULLOCK

Hypersensitizing plates. E. J. WALL. *Am. Annual Phot.* **42**, 163-6 (1928).—Instructions are given for hypersensitizing with NH_4OH , either plain or in combination with alc. or color-sensitizing baths. It has been claimed that ordinary plates treated with an alc.- H_2O NH_4OH soln. do not increase in speed. W. has, however, obtained increased densities in the "toe" of the H. and D. curve but the fog is also increased. Details of permissible dark room illumination and hints on quick drying are given. Ninck's hypersensitizing formula of ammoniacal Ag compn. is given as well as a modification which has a lower concn. Color sensitizing may be done at the same time as

the hypersensitizing or conducted separately. Plates to be hypersensitized may be color-sensitized in acid dye solns. The plates are not color-sensitive until after the NH_4OH treatment. Fog on hypersensitized film is reduced by bathing before development in the following soln.: Basic scarlet N, 0.02 g.; KBr, 5 g.; H_2O , 1 l. Other desensitizers may be used in the same manner.

L. MUEHLER

Covering power of photographic silver deposits. I. S. F. SHEPPARD AND A. BALLARD. *J. Frank. Inst.* 205, 659-89(1928).—A method is given for the rapid and accurate estn. of minute amts. of Ag (0.005-0.40 mg.) on photographic deposits. Small pieces of film (less than 1 sq. cm.) are accurately punched from the various densities on sensitometric strips. The punchings are given a preliminary treatment to solubilize the Ag, and the resulting Ag soln. is treated with dil. Na_2S soln. The yellow Ag_2S color is then compared in a micro-colorimeter with a standard Ag_2S color. For the 2 emulsions studied, Eastman Commercial film and Eastman Process film using P. A. P. developer, the covering power decreases with time of development. The values of covering power plotted against $\log E$ show a distinct tendency to give straight lines, which come nearer together as development proceeds. The covering power tends to decrease with increasing exposure. The mass of Ag has also been plotted as a function of time of development and of $\log E$. A table is given showing the covering power of development fog for various times of development. From the results obtained, there appears a more pronounced tendency for the D : $\log E$ curves to give a common point of convergence of the straight-line portions than for the mass of Ag: $\log E$ curves.

A. BALLARD

More about the Herschel effect. I. ÜPPO-CRAMER. *Phot. Rund.* 65, 209-11 (1928); cf. *C. A.* 21, 2852.—The destruction of the latent image, generally called the Herschel effect, on gaslight papers, is caused by red and by yellow light on many of the papers; and on some, by blue light. Consequently latent images on gaslight papers cannot be exposed too long to red or orange light in the printing process without partial destruction of the latent image.

E. R. BULLOCK

Schwarzschild effect as a regression phenomenon. LUPPO-CRAMER. *Phot. Ind.* 25, 495-8(1927).—L.-C. finds that with an iodo-bromide gelatin emulsion showing solarization readily, prep'd. according to a particular method, no appreciable difference is seen in the results on development when the time of exposure is increased, at const. H , from 1 min. to 144 min. If, however, a preliminary uniform exposure corresponding to max. density (but not further specified in the article) has been given, reversal becomes more extended on increasing the time of the subsequent const. H exposure. With a pure iodide gelatin emulsion and const. H exposure, the Schwarzschild effect, that is diminution of effective exposure when I is increased, is very pronounced. With pure bromide collodion emulsion that has been dried without addition of any preservative, the effect is only of the same order of magnitude as with fine-grained gelatin plates and not greater, as would be expected if the Schwarzschild effect were really a regression phenomenon.

E. R. BULLOCK

Dyes; photographic developers (Fr. pat. 632,273) 25.

Photographic diazotype process. KALLE & Co., A.-G. Brit. 280,593, Nov. 12, 1926. Neutral brown to black tints are obtained in a sensitive layer comprising a diazo comp'd. such as diazonaphtholsulfonic acid, an azo coupling component such as resorcinol and a metallic salt, by using as the metallic salt a salt of Ti such as Ti K oxalate. The tones may be modified by an after-treatment with a salt of a metal other than Ti, e. g., CuSO_4 .

Photographic films. TECHNICAL MOTION PICTURE CORP. Fr. 633,306, Apr. 25, 1927. Gelatin surfaces, particularly on celluloid films, are hardened by heating the surface in the presence of hardening agents, e. g., $\text{K}_2\text{Cr}_2\text{O}_7$ and a few drops of AcOH . After drying the film it is heated for a long time to 32-43°. The surface is then washed and dried.

Photographic films, etc. LUIKE KLAVER. Fr. 632,972, Apr. 19, 1927. See Brit. 269,912 (*C. A.* 22, 1289).

Combined phonographic and cinematographic films. C. A. HOXIE (to British Thomson-Houston Co.). Brit. 281,615, Dec. 2, 1926. Negatives of the pictorial and sound records are first produced on sep. films and these records are then combined on a single positive film. For the picture negative, a rapid emulsion is used and for the sound record a relatively fine-grain sensitive material is used in order to avoid "ground noises."

Cinematographic films. RODOLPHE BERTHON. Fr. 632,352, July, 20, 1926. On one face of the support a layer of celluloid or other plastic matter contg. in relief microscopic refractive particles for the selection of colors is applied and on the other side a layer of substance, permeable to gas, charged with azo compds. or azo compds. and phenols.

Cinematographic films. JOHN E. THORNTON. Fr. 632,334, Apr. 7, 1927. The method described in Brit. 214,934 (C. A. 18, 3011) is improved. Films of the kind comprising a transparent waterproof support carrying a ready-colored sensitive colloid layer upon which is a temporary reinforcing layer of paper are manufactured in two parts which are cemented together to produce the finished material. The back of the support may be coated with an anti-curling hardened gelatin layer.

Photographic prints. FRANZ VAN DER GRINTEN. Fr. 633,319, Apr. 15, 1927. In making prints contg. diazo compds. which become pale on exposure to light, reducing agents such as aldehydes or amino compds. are added to the sensitive film to prevent yellowing. The sensitive film may contain a compd. not having the power to couple but which is transformed into an azo compd. during development of the image with an alkali.

Developing photographic papers. EUGÈNE GAY. Fr. 632,452, Apr. 8, 1927. In the development of photographic papers by means of alk. vapors, a porous body projecting above the level of the liquid is placed in the ammoniacal tray to increase evapn.

Color photography. TECHNICOLOR MOTION PICTURE CORP. Fr. 633,305, Apr. 25, 1927. The dye compns or solns. used in the imbibition process are such as will be adsorbed on the negative in accordance with the development of the negative and will have the power to penetrate into the gelatin film. The dye may have a viscosity agent added, and it may be first treated with a colloid afterwards coagulated, *e. g.*, by boiling, and removed with assocd. impurities. A second dye having relatively low penetrability and high definition with respect to the film to be printed may be added. Two dye compns. for red and green, resp., are given.

Photographic sensitive material. F. VAN DER GRINTEN (TRADING AS CHEMI-CHE FABRIK L. VAN DER GRINTEN). Brit. 281,604, Dec. 11, 1926. A sensitive layer comprises an aromatic diazo compd. such as the diazotized deriv. of *p*-aminodimethylaniline-HCl or of *p*-aminodiethylaniline-HCl or 1-diisomylamino-2,6-dimethylbenzene-4-diazonium chloride or other diazo compd. having a tertiary N atom in the *p*-position to the diazo group and free from any substituent such as might form an anhydride with the diazo group. If the layer contains only the diazo compd. it is developed after exposure with a mixt. of alkali and an azo coupling component and if an azo coupling component is already present in the layer development is effected with alkali only, *e. g.*, with NH_3 gas. A salt such as BaCl_2 may be used in the layer to prevent bleeding of the developed azo dye and a non-volatile acid such as citric or tartaric acid may be added to prevent premature coupling if the azo coupling component is included in the layer.

Photographic emulsions. I. G. FARBERNIN. A.-G. Fr. 633,638, Apr. 30, 1927. In making photographic emulsions of Ag salts, imidazole or one of its derivs., such as nitrobenzimidazole or a complex protein product such as imidazolealanine, is added at any stage of the process.

Mono- and di-N-oxyethyl derivatives of *p*-aminophenol. I. G. FARBERNIN. A.-G. Brit. 280,873, Nov. 19, 1926. These compds., which may be used as photographic developers, are made by reaction of ethylene chlorohydrin, in either 1 or 2 mol. proportions, upon $p\text{-H}_2\text{NC}_6\text{H}_4\text{OH}$ by heating in the presence of KOH and alc. or of Na_2CO_3 .

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Osmium. III. E. FRITZMAN. Leningrad Univ. and Platinum Inst. of Acad. Sciences, Leningrad. *Z. anorg. allgem. Chem.* 172, 213-33 (1928).—A comprehensive review of the work of L. Chugaev on Os from 1916 to 1925 appearing mainly in inaccessible Russian journals. 1. Complex derivatives of osmium tetroxide. L. CHUGAEV AND I. CHERNYAEV. *Ibid* 216; cf. C. A. 20, 155. 2. The salt-forming properties of osmium tetroxide. L. CHUGAEV. *Ibid* 217; *J. Russ. Phys.-Chem. Soc.* 50, 294 (1918); *Mitteil. der Republ. II*, 124 (1920); cf. C. A. 12, 2504; KRAUSS AND WILKEN (C. A. 19, 2609).—Two g. OsO_4 , 1.5 g. KOH, 0.6 g. H_2O gave 2.4 g. of black $\text{OsO}_4 \cdot 2\text{KOH}$. Analyses

were carried out by titrating the base in the presence of Me orange and Os with $\text{Na}_2\text{S}_2\text{O}_8$ according to Klobie. $\text{OsO}_4 \cdot \text{RbOH}$, orange plates; $\text{OsO}_4 \cdot 2\text{RbOH}$ (?), red; $\text{OsO}_4 \cdot \text{CsOH}$, brown; $2\text{OsO}_4 \cdot \text{CsOH}$, orange plates; $2\text{OsO}_4 \cdot (\text{RhPy}_4\text{Cl}_4)\text{OH}$, yellow. In H_2O these salts form brownish yellow solns. and are largely hydrolyzed. 3. The distribution of osmium tetroxide between carbon tetrachloride and alkali. L. CHUGAEV AND A. I. LUKASHUK. *Ibid* 223; cf. Wartenburg (*C. A.* 19, 942); Yost and White (*C. A.* 22, 1290).—The soly. of OsO_4 in g. per 100 cc. of H_2O is 6.60 (25°), 5.30 (0°). The distribution coeff. of OsO_4 between CCl_4 and H_2O was found to be 14.3; between CCl_4 and 0.25 *N* NaOH only 0.90–3.635. 4. The velocity of distillation of osmium tetroxide from aqueous solutions. L. CHUGAEV AND M. BORODULIN. *Ibid* 227.—The distn. of OsO_4 from aq. solns. of K_2OsCl_6 is faster in the presence of HNO_3 and of acid KMnO_4 than in a stream of Cl_2 . 5. The catalytic decomposition of hydrogen peroxide by osmium tetroxide in the presence of alkali. L. CHUGAEV AND I. BIKERMAN. *Ibid* 229.— OsO_4 is one of the most active inorg. catalysts for the decompn. of H_2O_2 . 0.000001 *M* alkaline soln. accelerates this reaction. Above 0.001 *M* the rate of reaction is independent of the OsO_4 concn. The rate is max. in concns. of alkali from 0.005 to 0.01 *N*. 6. A new complex base of osmium. L. CHUGAEV. *Ibid* 231; cf. *C. A.* 13, 543; 20, 155. 7. Transformations in the series of osmiamic acid derivatives. L. CHUGAEV AND F. BOTKEVICH. *Ibid* 231; *J. Russ. Phys.-Chem. Soc.* 52, 424(1920).—Three g. $\text{K}_2(\text{Cl}_3\text{Os}=\text{N})$ reduced with SnCl_2 and HCl at 60° gave 0.6 g. $\text{K}_2(\text{Cl}_3\text{OsNH}_2)$. 1.5 g. $\text{K}_2(\text{Cl}_3\text{Os}=\text{N})$, 4.5 g. KOH , 4.5 g. H_2O treated with O_3 gave 0.55 g. $\text{K}(\text{O}_3\text{Os}=\text{N})$. Part of the product was pptd. as the difficultly sol. $\text{Cs}(\text{O}_3\text{Os}=\text{N})$. DAVID DAVIDSON

Rotatory dispersion of optically active coordination compounds. C. E. WOOD AND S. D. NICHOLAS. Univ. Birmingham. *J. Chem. Soc.* 1928, 1727–38.—Optically active coordination compds., in addn. to true anomaly, exhibit an anomaly that consists in the crossing of the zero axis from the neg. to the pos. region of rotation by the curve of rotation vs. wave length; this latter anomaly indicates the relative configuration. The configuration as deduced from dispersion data is in agreement with Werner's law. The algebraic sign of the hemihedral form of the coordination compd. considered indicates the relative configuration, but no generalization can be made at present.

C. J. WEST

Preparation and properties of a boride of cerium. L. ANDRIEUX. *Compt. rend.* 186, 1736 8(1928); cf. *C. A.* 22, 3100.—The electrolysis of CeO_2 dissolved in fused B_2O_3 is difficult, for the metaborate formed has a high m. p., and is not miscible with B_2O_3 in excess. Electrolysis of the mixt. $\frac{1}{2}\text{CeO}_2 + \text{B}_2\text{O}_3 + \frac{1}{2}\text{CeF}_3$ at 1000° by a current of 20 amp. gave blue-violet crystals of CeB_4 (I). The use of this bath has certain disadvantages. During the fusion and electrolysis, BF_3 is evolved; after the electrolysis, it is difficult to sep. the crystals of I; the quantities of CeO_2 and CeF_3 required are too large. Expts. with 10 different baths showed that the best one for the prepn. of I has the compn. (in g.-mols.): $\frac{1}{10}\text{CeO}_2 + 2\text{B}_2\text{O}_3 + \text{Li}_2\text{O}(\text{Li}_2\text{CO}_3) + \text{LiF}$. By using this bath, 10.83 g. of I was obtained from 15 g. CeO_2 after 2.5 hrs. of electrolysis. It is hard and will easily scratch quartz and topaz $d_s = 4.6$. It is not attacked by HCl , H_2F_2 or dil. H_2SO_4 . It is attacked by hot concd. H_2SO_4 , dil. HNO_3 and concd. HNO_3 . It is not attacked by alk. solns., but is decompd. at red heat by fused NaOH and KOH , by carbonates, nitrates and alk. bisulfates. It burns with difficulty in the air, but reacts violently when heated with PbO_2 or Na_2O_2 . LOUISE KELLEY

The constitution of silicates. WILHELM EITEL. *Naturwissenschaften* 16, 421–3 (1928).—A short review

B. J. C. VAN DER HOEVEN

Synthetic gems. M. K. HOFFMANN. *XI Ber. d. Freiburger Geol. Ges.* 1927, 11 pp.; *Chem. Zentr.* 1927, II, 156.—The synthesis of gems is carried out by 3 general methods (1) The individual components are mixed and fused with a flux, which yields only small crystals. (2) The gems form through chem. double decompn. in which case LiCl , salts of vanadic acid, of molybdic acid or tungstic acid, Fe, etc., are often used as flux. (3) The components are fused together without a flux. This method yields beautiful crystals. During the synthesis, the pressure must be so chosen that at the f. p. or just below it, the suspended gas bubbles occupy only the vol. which they occupy at ordinary temp. without pressure. The history of synthetic gems is outlined.

C. C. DAVIS

The reaction between chromic acid and manganous salt. RUDOLF LANG. *Z. anorg. allgem. Chem.* 170, 387–8(1928).—The reaction between $\text{Cr}_2\text{O}_7^{2-}$ and Mn^{2+} in acid soln. does not proceed unless an alkali fluoride or metaphosphoric acid is added. In the latter case addn. of 1:1 HCl will send the reaction in the reverse direction, Mn^{2+} being reduced to Mn^{3+} again. Fresh addn. of metaphosphoric acid will again reverse the direction. H. STOERTZ

Induction of the reaction between chromic acid and manganous salt by arsenious acid. RUDOLF LANG AND JOSEF ZWERINA. *Z. anorg. allgem. Chem.* 170, 389-96 (1928).—In the presence of As_2O_3 , Cr^{VI} is reduced to Cr^{III} and Mn^{II} oxidized to Mn^{III} . As^{III} is also oxidized to As^{V} . The amt. of Mn^{III} produced is detd. by treatment with AgNO_3 after adding HCl and measurement of the equiv. quantity of Cl liberated. The chromic acid remaining is detd. by titration with $0.1N$ FeSO_4 . The relation of Mn^{II} oxidized to As^{III} oxidized is known as the *induction factor*, and this is given for a series of expts. in which the quantity of MnSO_4 is varied. Regardless of the amt. of MnSO_4 , the induction factor is found to be about 0.5 at the beginning of the reaction, but becomes less as the reaction proceeds, for as the chromate concn. falls, Mn^{II} is reduced by As^{III} to an increasing extent. The presence of only a trace of KIO_3 produces great irregularity in the induction factor and lowers its initial value to about 0.25. The following equations are given for the induced reaction (1) $\text{Cr}^{\text{VI}} + \text{As}^{\text{III}} = \text{Cr}^{\text{IV}} + \text{As}^{\text{V}}$, (2) $\text{Cr}^{\text{IV}} + \text{Mn}^{\text{II}} = \text{Cr}^{\text{III}} + \text{Mn}^{\text{III}}$. H. STOERTZ

The constitution of silver subfluoride. J. BRODY AND TH. MILLNER. Vereinigten Glühlampen- und Elektrizitäts-A. G., Ujpest bei Budapest. *Z. anorg. allgem. Chem.* 172, 84-6 (1928); cf. *C. A.* 22, 1924 —Reply to Hettich (*C. A.* 22, 2118).

DAVID DAVIDSON

The constitution of silver subfluoride. CARLOS DEL FRESNO. Oviedo Univ., Spain. *Z. anorg. allgem. Chem.* 172, 256-64 (1928).—By analogy with H_2O and NH_3 , the energy of insertion of Ag atoms is >40 cal. and the calcd. heat of formation of Ag_2F considered as an insertion compd. of Ag into the AgF lattice is >15.5 cal. The formation of a F insertion compd. is not possible. These results are contrary to the calcs. of Brody and Millner (*C. A.* 22, 1924).

DAVID DAVIDSON

Ferrous hydroxide. E. DEISS AND G. SCHIKORR. State Material Testing Office, Berlin-Dahlem. *Z. anorg. allgem. Chem.* 172, 32-42 (1928).— $\text{Fe}(\text{OH})_2$ (I) sol. prep'd by repeated centrifugalizing and resuspending a ppt. of I, is positively charged as shown by semi-quant. pptn. expts. with electrolytes (Na_2SO_4 , NaCl , MgSO_4). I reacts with $\text{Fe}(\text{OH})_3$ to form a green intermediate product (II) and finally black Fe_3O_4 . II contains ferrous and ferric iron in the ratio of 1:1 and is formulated by D. and S. as $\text{H}_2\text{O} \cdot \text{Fe}_2\text{O} \cdot \text{Fe}(\text{OH})_2$. I is slowly oxidized by NH_4NO_3 , quickly by H_2O_2 . D. D.

Magnesium peroxide, $\text{MgO} \cdot 2\text{H}_2\text{O}$. H. KŘEPELKA AND J. ČERVINKA. *Časopis Československého Lékařnictva* 6, 153-8, 169-77 (1926).—The action of H_2O_2 on dry $\text{Mg}(\text{OH})_2$ yielded products difficult to define. By evap'g a mixt. of $\text{Mg}(\text{OH})_2$ and a concd. soln. of H_2O_2 in ether, a mixt. of $\text{MgO}_2 \cdot \text{H}_2\text{O}$ and $\text{MgO}_2 \cdot 2\text{H}_2\text{O}$ was obtained. $\text{MgO}_2 \cdot 2\text{H}_2\text{O}$ was isolated. The monohydrate took up H_2O until it reached the compn. of the dihydrate, and then began to decompose into compds. of the type $\text{MgO}_2 \cdot \text{MgO} \cdot \text{H}_2\text{O}$; in one case the mixt. corresponded to $4(\text{MgO}_2 \cdot 2\text{H}_2\text{O}) + \text{MgO}$. In absence of sufficient H_2O to reach the dihydrate stage, there was decompn. into O_2 and products difficult to define. H_2O_2 did not form addn. compds. with $\text{Mg}(\text{OH})_2$ or with the peroxides of Mg.

WILLIAM J. HUSA

Acetates of iron, nickel and other metals and a very basic crystalline ferric acetate. R. WEINLAND AND HERMANN HOLTMEIER. *Z. anorg. allgem. Chem.* 173, 49-62 (1928).—If to a soln. of FeCl_3 and the sulfate of Ni, Co or Mn" in H_2O , a soln. of CH_3COONa in H_2O is added, compds. of the type $[\text{Fe} \cdot \text{Ac}_3(\text{OH})_3]_x + 6\text{H}_2\text{O}$ are formed. They are sol. in H_2O to a deep red color, insol. in alc., sol. in pyridine, from which they can easily be crystd. If a CH_3COONa soln. is added to a soln. contg. $\text{Fe}(\text{NO}_3)_3$ and the nitrate of Zn, Cd or Mg, compds. of the type $[\text{Fe} \cdot \text{Ac}_3(\text{OH})_3]\text{Cd} + 7\text{H}_2\text{O}$ are formed, pale red in color, finely cryst., sol. in H_2O with a red color, sol. in AcOH , pyridine, slightly sol. in alc., decompd. by CH_3OH with formation of the golden green *dimethoxy-ferric acetate*, $\text{Fe}(\text{OCH}_3)_2 \cdot \text{CH}_3\text{COO}$. When strong CH_3COONa is added to a mixed soln. of $\text{Fe}(\text{NO}_3)_3$ and the nitrate of Ni, Co or Zn, compds. of the type $[\text{Fe} \cdot \text{Ac}_3(\text{OH})_3]\text{Ni}_4 + 23\text{H}_2\text{O}$ (A) are formed, bright brown in color, cryst., sol. in H_2O , dil. or concd. AcOH , pyridine and alc., but decompd. by MeOH . If A is dissolved in pyridine, warmed and crystd., the compd. $[\text{Fe}_4\text{Ac}_9\text{O}_3(\text{OH})]\text{Ni}_4 + 12\text{C}_4\text{H}_9\text{N}$ separates. It is bright olive-green, sol. in H_2O , alc. and pyridine. Analogous salts of Co and Mg are formed, as well as salts in which the acetate group is replaced by benzoate. If to a soln. of 5 g. of $[\text{Fe}_4\text{Ac}_9(\text{OH})_3]\text{Mg} + 10\text{H}_2\text{O}$ in 20 cc. H_2O , a soln. of 15.6 g. $\text{NaClO}_4 + \text{H}_2\text{O}$ in 20 cc. H_2O are added and the soln. is allowed to crystallize slowly, an ochre colored, *cryst. powder* separates, sol. in H_2O and slightly sol. in alc., and having the formula $[\text{Fe}_4\text{Ac}_9\text{O}(\text{OH})_3] + 7\text{H}_2\text{O}$. This may be dehydrated by drying over H_2SO_4 in a vacuum, and is decompd. by MeOH and $\text{C}_4\text{H}_9\text{N}$.

H. STOERTZ

The samarium subhalides. WILHELM PRANDTL AND HANS KÖGL. Bayer. Akad. der Wissenschaften, München. *Z. anorg. allgem. Chem.* 172, 265-72 (1928).— SmCl_3

pptd. as the hexahydrate with HCl is dehydrated in a stream of HCl which is then replaced by N_2 or by H_2 in the cold. Reduction is effected by carefully purified H_2 which is passed over a preliminary sample of $SmCl_3$. The temp. is raised from 450° to 600° after 15 hrs. and finally to 850° at the end of 70–80 hrs. Vessels of Au are superior to porcelain or Pt. The product is dark brownish red, dissolves in H_2O leaving some $SmOCl$. $SmCl_3$ heated to 1000° gives a sublimate of $SmCl_3$, while the Au vessel alloys with Sm. The ratio of Sm:Cl in the residue remains 1:2. Hg exts. Sm from $SmCl_3$ at 400° . N_2 does not react at 1350° . $SmBr_3$ is darker in color and exhibits the same behavior. The authors conclude that $SmCl_3$ is either a soln. of Sm in $SmCl_3$ or a compd. of these two (cf. Jantsch, Ruping and Kunze, C. A. 21, 2229). DAVID DAVIDSON

Preparation of sodium phosphomolybdate. A. SHACHOV. *Trans. Inst. Pure Chem. Reagents* (Russ.) 4, 74 9, *Chem. Zentr.* 1927, II, 37.—Directions are given for the prepn. of Na phosphomolybdate from NH_4 molybdate and Na phosphate. C. C. DAVIS

The classification of silica hydrates by means of the ammonia extraction procedure. WILHELM BILTZ and ERICH RAHLFS. *Z. anorg. allgem. Chem.* 172, 273–91(1928); cf. W. Biltz, C. A. 22, 704.—The findings of R. Schwarz on metasilicic and disilicic acids as true chem. compds. were confirmed, while "garnet" and trisilicic acids were found to be mixts. Liquid NH_3 is an ideal dehydrating agent for this type of hydrates since the influence of curved surfaces on vapor pressure is absent and it is very hygroscopic. Metasilicic acid hydrate prepd. from synthetic cryst. Na_2SiO_3 is powdery, settles well in water, is not cryst. to the eye. The acetone dried prepn. shows only traces of an x-ray diagram. Extn. with NH_3 yielded a hydrate $6SiO_2 \cdot 2H_2O$, which formed compds. with 1 to 4 mols. NH_3 . The decompn. curve was stepwise. Vapor dehydration of metasilicic hydrate yields H_2SiO_3 , the same formula as disilicic hydrate, but not behaving as the latter, but as a metasilicic deriv. Disilicic hydrate was prepd. from cryst. $Na_2Si_2O_5$. It settled easily in water and had a macroscopic leafy cryst. structure. The acetone-dried material had a significant x-ray figure. NH_3 does not remove any hydrate water. The hydrate combines with $3NH_3$ zeolithically, the loss being continuous. Vapor dehydration gives 2 hydrates, $6SiO_2 \cdot 2H_2O$ and $6SiO_2 \cdot H_2O$. The hydrate obtained depends on the original starting material and isomers are possible. It was not possible to prepare orthosilicic hydrate in the pure form. The ammo compd. indicates that it might be isolated by rapid manipulation from Li_4SiO_4 . The silica hydrates from the glassy forms of sodium metasilicate and sodium disilicate differ from the corresponding hydrates from the cryst. forms only in the state of subdivision. Metasilicic hydrate from glass does not lose its ammonia stepwise. Silica gels were prepd. from aq. solns. of sodium metasilicate, sodium disilicate, tech. sodium silicate and from $SiCl_4$. The ammonia decompn. curves resembled adsorption curves, no stoichiometric relations were observed, and aging decreased the absorptive capacity. The behavior of the hydrates from cryst. silicates was independent of age. The hydrate obtained from a sample of heulandite behaved in ammonia extn. and vapor pressure exactly as a disilicic hydrate. The formula of heulandite used is expressed as $(6SiO_2 \cdot 0.995Al_2O_3) \cdot 0.833CaO \cdot 0.088Na_2O \cdot 5.45H_2O$. The hydrate is obtained by the soln. of the mol. outside the bracket and then the substitution of water for the Al_2O_3 . A. F.

The classification of alumina hydrates by the ammonia extraction procedure. WILHELM BILTZ, GUSTAV A. LEHRER AND KARL MEISEL. *Z. anorg. allgem. Chem.* 172, 292–309(1928).—Willstätter's metahydroxide, hydroxides A, B, C_α , C_β , C_γ , Bornsdorff's hydrargillite, "Indian" alumina, aluminum hydroxide as in analytical work, Kohlschütter's topochem. gel and Böhm's artificial bauxite were prepd. and treated by the acetone and ammonia extn. procedures. Of these, Willstätter's compds., hydrargillite, Kohlschütter's gel, and bauxite were found to be definite chem. compds. and to give diffraction diagrams. Hydrargillite and bauxite are one type of compd. whose lattice is too stable to permit the formation of hydrates and ammoniates. Willstätter's metahydroxide is considered as a reactive bauxite of formula $(Al_2O_3 \cdot H_2O)$. A and B are bauxite hydrates $(Al_2O_3 \cdot H_2O) \cdot 0.5H_2O$ and $(Al_2O_3 \cdot H_2O) \cdot H_2O$. C_α is a bauxite dihydrate, unstable and changing in time to C_β , which in turn changes under water to C_γ , a hydrate resembling hydrargillite. ARTHUR FLEISCHER

The composition of the precipitate which forms from the action of potassium ferrocyanide upon calcium salts in the presence of acetic acid. IV. TANANAEV. *Z. anorg. allgem. Chem.* 172, 403–6(1928).—The ppt. was obtained by using either an excess of dil. Ca salt or by using an excess of ferrocyanide. To det. Fe and Ca the ppt. (dried) was carefully heated to burn off C, the residue dissolved, $Fe(OH)_3$ and then CaC_2O_4 pptd. K was detd. after removing ferrocyanide as Ag ferrocyanide. The compn. of the ppt. was found to be $K_2CaFeCaNa$. ARTHUR FLEISCHER

Liquid ammonia as a solvent and the ammonia system of compounds. II. In-

organic ammonia compounds. W. CONARD FERNELIUS AND WARREN C. JOHNSON. *J. Chem. Education* 5, 828-35(1928).—A further explanation of the ammonia system of compds of Franklin, Kraus *et al.* (cf. C. A. 22, 3082). Whereas ordinary acids, bases and salts may be considered as derived from H_2O by replacing H with acid groups, metals or both acid groups and metals, just so NH_3 can have its H replaced by acid groups (as in $CINH_2$ and $N \equiv N = NH$), metals (as in KNH_2), and both acid groups and metals (as in $CaNCN$). The analogies of hydrolysis and ammonolysis, of amphoteric hydroxides and amides, of ordinary basic salts and of ammonobasic salts, etc., are explained in terms of Franklin's theories. Similarly S, halogens and other substances may be taken as the basis of systems of compds. comparable to the ordinary substances derived from H_2O theoretically. W. C. EBAUGH

Complex formation in stannous chloride and stannous bromide solutions. MILDA PRYTZ. Kgl. tierärztlichen u. landw. Hochschule, Kopenhagen. *Z. anorg. allgem. Chem.* 172, 147-66(1928).—Using the equation $E = E_0 - 0.02955 \log a_{Sn} - E_0 - 0.02955 \log C_{Sn} - 0.02955 \log f$, where E = the measured potential referred to the normal H_2 electrode and corrected for diffusion potential according to Henderson, E_0 = the normal potential, and f = the activity coeff. of Sn calcd. from the formula of Debye and Huckel, the normal potential of Sn^{2+}/Sn (in perchlorate soln.) was found to be 0.1359 v. (The potential of the 3.5 M calomel electrode was taken as 0.2505 v.) The potential of Sn^{2+}/Sn in 0.01 M $SnCl_2$ and $SnBr_2$ indicates a marked decrease in the stannous ion with increasing activity of the halide ion. The following consts. were calcd.: $C_{SnCl_2}/(a_{Sn^{2+}} \cdot C_{Cl^-}) = 32$; $C_{SnCl_2}/(C_{SnCl_2} \cdot C_{Cl^-} f^2) = 5.5$; $C_{SnCl_2}/(C_{SnCl_2} \cdot C_{Cl^-} f^2) = 0.6$; $C_{SnCl_2} f^2/(C_{SnCl_2} \cdot C_{Cl^-} f^2) = 0.3$; $C_{SnBr_2}/(a_{Sn^{2+}} \cdot C_{Br^-}) = 13$; $C_{SnBr_2}/(C_{SnBr_2} \cdot C_{Br^-} f^2) = 5$; $C_{SnBr_2}/(C_{SnBr_2} \cdot C_{Br^-} f^2) = 0.44$ (C = concn; a = activity; f = activity coeff. of the halide ion; f' = activity coeff. of the stannous ion). Within certain limits the consts. of the complex ions $SnCl_4$ and $SnBr_4$ are approx proportional to the halide-ion concn. DAVID DAVIDSON

Complex anions of meconic and quinic acids with heavy metals. R. WEINLAND AND HEINRICH FRIEDE. Univ. Würzburg, *Arch. Pharm.* 266, 353-66(1928).—The following compds. were prepd and characterized: *trisodium dimeconatoferrate*, $[Fe(OC_6H_3(COO)_2)_2]Na_3$; *triguanidine dimeconatoferrate*, $[Fe(OC_6H_3(COO)_2)_2]H_3 \cdot 3(CN_3H_3) + 6H_2O$; *tribipyridine dimeconatoferrate*, $[Fe(OC_6H_3(COO)_2)_2]H_3 \cdot 3(C_5H_5N) + 5H_2O$; *monocyanurium dimeconatoferrate*, $[Fe(OC_6H_3(COO)_2)_2]H_3 \cdot NH_3 + 5H_2O$; *monopyridine dimeconatoferrate*, $[Fe(OC_6H_3(COO)_2)_2]H_3 \cdot C_5H_5N + 5H_2O$; *monoguanidine dimeconatoferrate*, $[Fe(OC_6H_3(COO)_2)_2]H_3 \cdot CN_3H_3 + 5H_2O$; *monoguanoline dimeconatoferrate*, $[Fe(OC_6H_3(COO)_2)_2]H_3 \cdot C_5H_5N + 6H_2O$; *dimeconatoferrate with 1.75 Na*, $[Fe(OC_6H_3(COO)_2)_2]H_{1.75}Na_{1.75} + 20H_2O$; *dimeconatoferrate with 1.75 C_5H_5N* , $[Fe(OC_6H_3(COO)_2)_2]H_{1.75}(C_5H_5N)_{1.75} + 20H_2O$; *pyridine chlorodimeconatochromate*, $[Cr(OC_6H_3(COO)_2)_2Cl]H_4 + C_5H_5N + 7H_2O$; *copper ammonia meconate*, $Cu_3(OC_6H_3(COO)_2)_2 + 6NH_3 + 8H_2O$; *copper pyridine meconate*, $Cu_3(OC_6H_3(COO)_2)_2 + 4C_5H_5N + 8H_2O$; *zinc ammonia meconate*, $Zn_3(OC_6H_3(COO)_2)_2 + 4NH_3 + 8H_2O$; *tripotassium triquinatoferrate*, $[Fe(OC_6H_3(COO)_2)_2]K_3 + 12H_2O$; *tribipyridine triquinatoferrate*, $[Fe(OC_6H_3(COO)_2)_2]Rb_3 + 12H_2O$. W. O. E.

Complex salts of cobalt having univalent ions. F. M. JAEGER AND P. KOETS. *Z. anorg. allgem. Chem.* 170, 347-69(1928).—If a soln. of triamino triethylamine, $N(CH_2CH_2NH_2)_3$, (A), acts upon praseo-diethylenediamine-dichlorocobaltichloride or upon diethylenediamine chloraquaacobaltic sulfate, a compd. contg. the complex

Co ion, $\left\{ \begin{array}{c} (En)_3 \\ (Triam)_3 \end{array} \right\} IX$, is formed. In the formula used (En) represents ethylene

diamine and (Triam) represents triaminotriethylamine. The presence of an uneven no. of C atoms led to the belief that stereoisomeric compds. contg. this complex might exist, so many of its derivatives were prepd. A is prepd. by passing NH_3 for 10 hrs. at $140-150^\circ$ into fused β -bromoethyl phthalimide. The product is extracted 3 times with 97% alc., and the residue recrystd. from boiling glacial AcOH. The triphthalyl-triaminotriethylamine thus formed is treated with strong HCl at 150° for 2 hrs., the mass dild. with H_2O , and then treated with alc. + Et_2O , which ppts. the hydrochloride of the base A, spin-ile like, colorless bipyramids or somewhat thicker hexagonal tablets.

To prepare a salt of the complex nonavalent Co ion, the compd. $\left\{ \begin{array}{c} (En)_3 \\ CoCl \\ H_2O \end{array} \right\} Cl_3$, (B), is treated with a dil. soln. of A in H_2O and heated for 4 hrs. on the H_2O bath.

The compd., $\left\{ \begin{matrix} (\text{En})_6 \\ \text{Co}_3 \\ (\text{Triam})_2 \end{matrix} \right\} \text{Cl}_3 + 6\text{H}_2\text{O}$, is formed. The H_2O -free iodide is prepd. from this by treatment with a concd. soln. of NaI , and is crystd. in the form of thick, dark colored, gleaming crystals, or in the form of blood-red needles or somewhat thicker pillars. The following salts of this type are prepd., and their cryst. form is studied in detail: $\left\{ \begin{matrix} (\text{En})_6 \\ \text{Co}_3 \\ (\text{Triam})_2 \end{matrix} \right\} (\text{SO}_4)_3 + 8\text{H}_2\text{O}$; $\left\{ \begin{matrix} (\text{En})_6 \\ \text{Co}_3 \\ (\text{Triam})_2 \end{matrix} \right\} (\text{NO}_3)_3 + 4\text{H}_2\text{O}$; $\left\{ \begin{matrix} (\text{En})_6 \\ \text{Co}_3 \\ (\text{Triam})_2 \end{matrix} \right\} (\text{ClO}_4)_3 + 6\text{H}_2\text{O}$; $\left\{ \begin{matrix} (\text{En})_6 \\ \text{Co}_3 \\ (\text{Triam})_2 \end{matrix} \right\} (\text{S}_2\text{O}_8)_3 + 18\text{H}_2\text{O}$. In all these salts no indication of stereoisomerism is given. To test this further an iodo-*d*-tartaric acid derivative is prepd. - $\left\{ \begin{matrix} (\text{En})_6 \\ \text{Co}_3 \\ (\text{Triam})_2 \end{matrix} \right\} \text{I}_3 + 3\text{H}_2\text{O}$. The only optical activity obtained was that derived from the tartaric acid, as the iodide prepd. from the iodo-tartrate is identical with the iodide prepd. from the chloride. The authors conclude that the complex Co ion is represented by the formula $\left\{ \begin{matrix} (\text{Triam}) \\ [\text{Co}(\text{En})_2]_3 \\ (\text{Triam}) \end{matrix} \right\} \text{IX}$.

H. STOERTZ

Cyanogen compounds of the platinum metals. II. Cyanogen compounds of ruthenium. F. KRAUSS AND G. SCHRADER. *Z. anorg. allgem. Chem.* 173, 63-72 (1928); cf. *C.* 1, 21, 3846. To a soln. of $\text{K}_4[\text{Ru}(\text{CN})_6] \cdot 3\text{H}_2\text{O}$ in H_2O an equal vol. of 4 *N* H_2SO_4 is added, and the mixt. is boiled until a flocculent, deep blue ppt. is formed, which is filtered, washed with NH_4Cl soln., H_2SO_4 and hot H_2O and dried in a vacuum at 150° . The compd. thus prepd. is $\text{Ru}(\text{CN})_6 \cdot \text{H}_2\text{O}$ (A); it is strongly hygroscopic, stable in acids and alkalis, and sol. in concd. NH_4OH . If A is dissolved in NH_4OH and NH_3 conducted into the soln. while it is boiled down to a small vol., the soln. being finally evapd. to dryness in a vacuum desiccator over KOH , the compd., $\text{NH}_4[\text{Ru}_2(\text{CN})_{12} \cdot 4\text{NH}_3]$ (B), is formed, blue, sol. in H_2O to a golden brown soln., from which heavy metal ions ppt. compds. such as $\text{Ni}[\text{Ru}(\text{CN})_6 \cdot 4\text{NH}_3]_2 \cdot 7\text{H}_2\text{O}$. This is prepd. by adding a soln. of B in H_2O to a boiling dil. NiSO_4 soln. The bright green ppt. is filtered, washed with hot H_2O and dried. It is practically insol. in H_2O , sol. in NH_4OH , decomposed by acids to form A. The Cu compd., $\text{Cu}[\text{Ru}(\text{CN})_6 \cdot 4\text{NH}_3]_2 \cdot 5\text{H}_2\text{O}$ (C), is prepd. in an analogous manner and is a chocolate brown, crust. powder, unstable in acids. On dissolving C in concd. NH_4OH the compd., $\text{Cu}[\text{Ru}_2(\text{CN})_{12} \cdot 4\text{NH}_3] \cdot 4\text{NH}_3$, is formed, bright brown, crust., sol. in dil. NH_4OH , sol. in H_2O with difficulty, fairly stable in acids. If Cl is conducted into a neutral soln. of $\text{K}_4[\text{Ru}(\text{CN})_6] \cdot 3\text{H}_2\text{O}$, the soln. finally becomes reddish brown. An equal vol. of 3 *N* H_2SO_4 is added and on warming a dark green ppt. is formed, which on filtering and drying over CaCl_2 in a vacuum at room temp. shows the compn., $\text{Ru}(\text{CN})_6 \cdot 5\text{H}_2\text{O}$ (D). Drying at 200° forms the monohydrate. If D is dissolved in hot NH_4OH and NH_3 gas is passed into the soln., the compd., $[\text{Ru}(\text{CN})_6 \cdot \text{H}_2\text{O} \cdot 2\text{NH}_3]_3$, is formed, insol. in H_2O , decomposed by alkalis. The free acid, $\text{H}_4[\text{Ru}(\text{CN})_6]$, forms compds. with organic bases of high mol. wt., which are cryst. and difficultly sol. in H_2O . The brucine compd. has the formula $[\text{C}_{27}\text{H}_{25}(\text{O} \cdot \text{CH}_3)_5 \cdot \text{O}_2 \cdot \text{N}_2\text{H}_2] [\text{H}_2\text{Ru}(\text{CN})_6]$ and the strychnine compd. the formula $[\text{C}_{21}\text{H}_{22}(\text{O} \cdot \text{N}_2\text{H}_2)_2] [\text{H}_2\text{Ru}(\text{CN})_6]$. H. STOERTZ

Oxysiloxenes. H. KAUSKY AND H. THIELE. *Z. anorg. allgem. Chem.* 173, 115-24 (1928). - *Monooxysiloxene* is prepd. by hydrolysis of $\text{Si}_2\text{O}_5\text{H}_2\text{Br}$ with alc. contg. about 20% H_2O and acidified with a few drops HCl : $\text{Si}_2\text{O}_5\text{H}_2\text{Br} + \text{H}_2\text{O} = \text{Si}_2\text{O}_5\text{H}_4\text{OH} + \text{HBr}$. In a similar way the di-, tri-, tetra- and hexaoxysiloxenes are prepd. from the respective halides, the colors running from yellow through red and violet to black. They are very unstable and possess strong fluorescence and chemiluminescence. Since the hydrolysis of the halogen compds. of siloxen is reversible, the oxysiloxenes produced behave like weak bases, and the OH groups can be replaced by acid residues such as sulfate, phosphate, halogenide, formate, acetate, etc. The oxysiloxenes can also be prepd. by action of SO_2 on siloxen or any SiH compd., H_2S being left in soln. A soln. of SO_2 in acetone is more advantageous, as no S separates. The explosive nature of these compds. is due to the occurrence of SiOH groups and Si-Si linkage, as well as the grouping Si-acyl .

H. STOERTZ

7—ANALYTICAL CHEMISTRY

W. T. HALL

Methods of analysis used in the metallurgical industry. L. PERSOZ. *Rev. chim. ind.* 37, 190-3(1928); cf. *C. A.* 22, 2895.—Details are given for the analysis of dolomite, lime, phosphorus slag, ferromanganese, spiegeleisen and ferrosilicon and for the detn. of Mn, Si, S, P, As, Cu and C in cast iron. P. THOMASSET

The periodic system and the system of analytical chemistry. J. GILLIS. *Natuurw. Tijdschrift* 10, 47-52(1928).—A review. B. J. C. VAN DER HOEVEN

Spectral analytical measurements. J. VERHAEGHE. *Natuurw. Tijdschrift* 10, 10-7, 53-7(1928).—A review. B. J. C. VAN DER HOEVEN

Indicator for oxidizing agents. D. S. DAVIS. *Chemist-Analyst* 17, No. 3, 4 (1928).—To det. whether any free Br_2 , Cl_2 , HClO or HNO_3 remains in a boiling aq. soln., add a little methyl orange, which will be decolorized if any of these oxidizers are present. W. T. H.

Simplified method of differential potentiometric titration. NORRIS F. HALL, MARK A. JENSEN and SVEN A. BAECKSTROM. Harvard Univ. *J. Am. Chem. Soc.* 50, 2217(1928).—The method of Mac-Innes and Jones for differential electrometric titration can be simplified by leading one of the electrode wires into a medicine dropper around which the other electrode is wound. The liquid in the dropper is stagnant and therefore at a different concn. than the soln. outside the dropper which has been partly titrated. W. T. H.

New method of potentiometric volumetric analysis. BOGDAN KAMIENSKI. *Bull. intern. acad. Polonaise* 1928, 33-60.—Recently several papers have appeared, obviously written without knowledge of the other work, in which an improved method of differential titration is proposed depending upon the use of 2 electrodes, one of them immersed directly in the stirred and titrated soln. while the other is in a narrow tube surrounded by soln.; the soln. diffuses very slowly into the main body of liquid so that an e. m. f. results between the 2 electrodes and reaches a max. when the titration is finished. This paper is the most pretentious of all these recent publications and is an exptl. study based on mathematical studies. The oxidations of Fe^{++} to Fe^{+++} , of $[\text{Fe}(\text{CN})_6]^{4-}$ to $[\text{Fe}(\text{CN})_6]^{3-}$, Cr^{+} to Cr^{++} and Sn^{+} to Sn^{++} were studied. All the exptl. details are described explicitly as well as the app. used. A method for prepg. Cr^{++} solns. also is given. W. T. H.

Rapid volumetric determination of calcium oxide and magnesium oxide in mixtures. N. M. MILOSLAVSKI and E. A. BILENKO. Ukrainian Institute of Applied Chemistry. *Ukrainskii Khim. Zhurnal* 3, No. 1, tech. pt., 37-41.—The method of Willstatter and Waldschmidt-Leitz (published in *Berichte* 19, 1223), with insignificant modifications, has been thoroughly tested by M. and B. and has been found by them applicable to factory labs. Not more than 1-1½ hrs. is required for a determination of Ca and Mg by this method. BERNARD NELSON

Quantitative precipitations at extreme dilutions. V. NJEGOVAN and V. MARJANOVIĆ. *Z. anal. Chem.* 74, 191(1928); cf. *C. A.* 22, 1927.—A correction. One cc of satd. BaCl_2 ppt. about 0.125 g. of SO_4 . In the method 3 cc of soln. should be used where 1 cc. was specified. W. T. H.

Use of constant-weight filters in quantitative analysis. B. ORMONT. Kiev Polytechnicum. *Ukrainskii Khim. Zhurnal* 3, No. 1, sci. pt., 47-58.—Gooch crucibles are not satisfactory for use in alk. soln. Expts. with filter papers show that it is extremely difficult to dry them to const. wt. in the old-fashioned way. B. N.

Gallium. III. Quantitative separation of iron from gallium by means of α -nitroso- β -naphthol. JACOB PAPISH and L. E. HOAG. Cornell Univ. *J. Am. Chem. Soc.* 50, 2118-21(1928); cf. *C. A.* 22, 929.—From a soln. of $p_H < 7$, a 2% soln. of α -nitroso- β -naphthol in 50% AcOH will ppt. Fe^{+++} and no Ga^{+++} . In the filtrate, after evap. to dryness to remove the AcOH , the Ga can be pptd. as hydroxide and the ignited Ga_2O_3 contains no appreciable Fe. W. T. H.

Colorimetric method of determining reducing substances. S. S. FROLOV and K. O. SVETLYAKOV. Ivanovo-Voznesensk Polytechnicum. *J. Chem. Ind. (Moscow)* 4, 545-7(1927).—In employing Fehling soln. for detn. of reducing substances (such as sugar, starch, cellulose derivs.), the amt. of reagent required is usually detd. either from the wt. of the Cu_2O ppt. or by titration of the remaining soln. Instead of this, a colorimetric detn. of Cu remaining in soln. is recommended. The optical consts. of Fehling soln. in various concns. were detd. with the Bock-Benedict colorimeter and

very rapid and exact results were obtained in test analyses, provided not less than 0.088 mg. of Cu per cc. remained in soln. BERNARD NELSON

New method for the colorimetric determination of small quantities of antimony and their separation from tin. S. G. CLARKE. *Analyst* 53, 373-9(1928).—A method is described for the detn. of small amts. of Sb in high-grade Sn based on the pptn. of Sb from chloride solns., by the Reinsch reaction and the colorimetric detn. of Sb, after stripping the deposited film with Na_2O_2 soln., on the basis of the golden-yellow color formed by the reaction of Sb soln. with pyridine and an iodide. W. T. H.

The detection and the colorimetric determination of carbon monoxide. K. SCHULTZE. *Glückauf* 62, 1496-7(1926); *Chem. Zentr.* 1927, I, 632; cf. Kast and Selle, *C. A.* 21, 2630.—The utility of PdCl_2 paper is impaired by keeping. Uniformity of color cannot be obtained, which leads to uncertainty. During the War, test tubes with Thiele NH_3 -Ag solns. were only occasionally unsatisfactory. It proved advantageous to make the upper pointed end of the ampoules finer as well as to replace it by a thick-walled capillary. C. C. DAVIS

A simple method of determination of arsenic in small quantities of organic substances. O. WINTERSTEINER AND H. HANNEL. *Univ. Graz. Mikrochemie* 4, 155-67; *Chem. Zentr.* 1926, II, 3065.—The method depends upon the fact that during the destruction of the org. substance, As is oxidized to arsenate; this liberates I from KI, which can be titrated with $\text{Na}_2\text{S}_2\text{O}_4$. *Procedure.*—Boil 7-12 mg. of substance with 1 cc. of 30% H_2SO_4 and a few drops of concd. HNO_3 , add more HNO_3 and boil longer, evap. several times with addn. of a few drops of perhydrol, dissolve in 1 cc. of water, evap. until SO_3 is evolved, repeat this process, add 1 cc. of water, boil out of contact of air, add fresh concd. HCl and 2 cc. of 4% KI soln. (free of iodates), let stand closed for 10 min. and titrate the I with 0.01 N $\text{Na}_2\text{S}_2\text{O}_4$. If the soln. is only pale yellow, make it up to 20 cc., add 5 drops of 1% starch soln., and titrate to the appearance of a characteristic pale reddish end point. When halogens are present in the org. substance, special precautionary measures are necessary to obtain correct results. The method gives reliable results and is particularly serviceable in elementary org. analysis. C. C. DAVIS

The determination of carbon on the basis of the fracture structure. MATSUJIRO HAMASUMI. *Arch. Eisenhüttenwesen* 1, 157-60(1927).—In studying the effect of C on the fracture of steels with 0.1-0.9% C, expts. show that the bending angle, hardness and microscopic structure are influenced more by C when it is present in amts. less than 0.3% than when present in greater amts. An Fe-Mn-C diagram is plotted to show the effect of Mn on the structure of the fracture. From this it appears that increase of Mn displaces the eutectic point toward the Fe-Mn side, causing a decrease in the eutectoid temp. Similarly the weak appearance of acid steels can be explained from the raising of the transition point by the addn. of Si to C-poor steels. J. B.

Rapid method of determination of carbon in iron and steel. N. M. MILOSLAVSKII AND V. P. VEPRITZKII. *Ukrainskii Khim. Zhurnal* 3, No. 1, tech. pt., 31-5(1928).—De Nolly's method (cf. *C. A.* 5, 1888) has been thoroughly examined and has been found correct only in the case when C content is not over 1%. BERNARD NELSON

A new method for determining copper in iron and steel. EMIL ZINDEL. *Chem.-Ztg.* 52, 537-8(1928).—Treat 5 g. of sample with 40-50 cc. of 6 N HCl , filter as soon as the sample is all decomposed and dil. with 400 cc. of hot water. Heat to boiling and add 100 cc. of 10% $\text{Na}_2\text{S}_2\text{O}_3$ soln. Filter, wash with 500 cc. of water, ignite the ppt and weigh as CuO . W. T. H.

Rapid method for determining copper. G. SPACU AND J. DICK. *Bul. soc. stiinta Cluj* 4, 23-7(1928).—The method depends upon the pptn. of $[\text{CuPy}_2](\text{SCN})_2$, which contains 18.87% of Cu. Only alkali, alk. earth and Mg ions can be present. To 75-100 cc. of Cu soln. add 8-20 drops of pyridine, or enough to impart an azure blue color, and 0.5 g. of NH_4CNS . Stir well and filter into a filtering crucible. Wash with a water contg. 3 g. NH_4CNS and 3 cc. of pyridine per l., then with an alc. wash prepared by adding 8 cc. of pyridine and 0.5 g. of NH_4CNS to one l. of 75% alc. Finally wash with ether and dry in a vacuum of an oven heated to 40-45°. W. T. H.

A new, rapid method for determining manganese. G. SPACU AND J. DICK. *Z. anal. Chem.* 74, 188-91(1928).—If an alk. soln. of Mn^{++} is treated with alkali thiocyanate and an excess of pyridine, the Mn is completely pptd. as $(\text{MnPy}_4)(\text{SCN})_2$. The ppt. can be weighed after suitable washing and drying. Some 20 expts. with pure Mn^{++} solns. show that the method is accurate and rapid. Since the Mn compd. is not pptd. when only little thiocyanate and pyridine are present, it is hoped that a method can be worked out for sepg. Mn^{++} from Co^{++} , Ni^{++} etc., which cations give more insol. pyridine complexes. W. T. H.

Volumetric determination of mercury. LOUIS MARICQ. Brussels Univ. *Bull. soc. chim. Belg.* 37, 241-51(1928).—The electrotitration of the Hg salts with KI is the only correct procedure in the case of 0.1-0.001 N Hg solns. The presence of HNO_3 , H_2SO_4 , chlorides, phosphates or acetates does not influence the titration. The KI soln. may be titrated with a blank or by electrotitration with AgNO_3 ; in this case, a correction coeff. 0.994 is to be used; it is independent of the diln. A. L. HENNE

Determination of small quantities of phosphorus by the method of Denigès. V. V. CIUREA. *Bul. soc. chim. Romania* 9, 869(1928).—For detg. small quantities of P (1-5 mg. of P_2O_5) Denigès treated the phosphate soln. with sulfo-molybdate reagent and detd. the P content colorimetrically, Mo blue being formed. Unfortunately the color is not directly proportional to the P content and different observers do not always agree with respect to the depth of color. To overcome this difficulty, it is now recommended to add standard Cl_2 water until the blue is bleached. Place 1-5 cc. of the soln. in a conical flask, add water enough to make the vol. 5 cc. and then add 4 drops of Denigès sulfo-molybdate soln. Shake and add 4 drops of freshly prepd. SnCl_2 soln. Do the same thing with solns. contg. known quantities of P. After 10 min., add 10-15 cc. of water and from a microburet, drops of Cl_2 aq. until the soln. is just decolorized. W. T. H.

A rapid gas-volumetric determination of potassium. GERHART JANDER AND HERMANN FABER. *Z. anorg. allgem. Chem.* 173, 225-32(1928).—By pptg. $\text{NaK}_2\text{Co}(\text{NO}_2)_6$ from a nearly satd. NaCl soln. the ppt. is of const. compn. By treatment of the ppt. with acid and FeSO_4 soln. all of the nitrite radical is converted into NO gas, which can be measured. In this way a rapid and accurate detn. of K can be accomplished. Alk. earths are preferably removed by treatment with Na_2CO_3 . NH_4 salts must be present. To det. K in a commercial salt proceed as follows. Dissolve 3 g. of salt in a little hot water, add 1-2 cc. of 4% Na_2CO_3 soln., filter and wash. Make the filtrate acid to methyl orange with HCl, dil. to exactly 100 cc., mix and take 2.5 cc. of the soln. for the further analysis. Ppt. the K with 1.5 g. of $\text{Na}_3\text{Co}(\text{NO}_2)_6$ dissolved in 30 cc. of satd. NaCl soln. The reagent must be freshly prepd. Stir with a mechanical stirrer for 3 min. and wash with satd. NaCl soln., using 30 cc. in all. Transfer the ppt. to an evolution flask, connect with the gas buret, through a reflux condenser, expel all air from the app. by a rapid stream of CO_2 and add a concd. soln. of FeSO_4 in 2 N H_2SO_4 . All the NO can be removed by heating the flask and eventually forcing CO_2 through the liquid, using KOH to dissolve this gas at the buret. The entire procedure requires less than an hour and the results are surprisingly good. W. T. H.

Estimation of zinc by the iodate method. GORDON EASTWOOD AND A. M. MUNRO. *Chem. Eng. Mining Rev.* 20, 322(1928).—To the barely acid soln. add 20 cc. of reagent prepd. by dissolving 27 g. of HgCl_2 and 39 g. of KCNS separately and finally dilg. the mixed solns. to one liter. 10 cc. of this reagent will ppt. 0.09 g. of Zn as $\text{ZnHg}(\text{SCN})_4$. Stir 5 min. and allow to stand for at least 1 hr. Filter and wash with water contg. 1% of the thiocyanate reagent. Dissolve the ppt. in a cold mixt. of 35 cc. concd. HCl, 10 cc. of water and 5 cc. of CHCl_3 or CCl_4 . Titrate carefully with standard KIO_3 soln. Cu, Mn, Co, Bi, Cd and mercurous Hg interfere as they give insol. thiocyanates. W. T. H.

The determination of vanadium in high-speed steels and its waste in producing these steels. A. FOLSNER. *Stahl u. Eisen* 47, 28-30; *Chem. Zentr.* 1927, I, 1504.---A method of Svensson for detg. V in steel (cf. *Stahl u. Eisen* 28, 853(1908)) gives results which are far too low. The following method is proposed. Dissolve 2-4 g. of steel in 50 cc. of concd. HCl, evaporate with a few cc. of HNO_3 , dissolve in 20 cc. of concd. HCl, dil., neutralize, pour in hot aq. NaOH (30 g. in 100 cc.), dil. to 500 cc., filter off 250 cc., acidify with HCl, boil, add 20 g. of NH_4Cl , make weakly ammoniacal, ppt. with 30 cc. aq. MnCl_2 (1:10), add 20 cc. of NH_4OH (d. 0.91), again boil a short time, let stand 3 hrs., filter, dissolve the ppt. in 50 cc. of hot HCl (1:1), add 30 cc. of concd. H_2SO_4 , evaporate, cool, reduce with 25 cc. of HCl (2:1), evaporate again, cool, make up with water (free of O) to 200 cc. and titrate at 80-85° with aq. KMnO_4 according to the method of Treadwell. C. C. DAVIS

Analysis of stainless steel. WM. KUEBLER, WM. SHANEMAN, J. GALLAGHER AND B. INGRAM. *Chemist-Analyst* 17, No. 3, 6-8(1928).—The analysis of stainless steels, irons, heat-resisting alloys, etc., is often difficult because of the insol. of these materials. They often do not respond well at all to the conventional methods of dissolving steel. In this paper the chemical analyses of 14 materials of this nature are given and directions for dissolving them for the detns. of C, Mn, P, Si, Ni, W, Cr, Cu and Mo. W. T. H.

Studies of the determination of sulfur in inorganic compounds. H. TER MEULEN. *Diss. Delft* 1925, 86 pages; *Chem. Zentr.* 1927, I, 325.—A method is recommended

which is based on the conversion of Na to Na_2S by fusion with Na_2CO_3 and C. The Na_2S is decompd. with dil. acid and the H_2S detd. iodometrically. Another method is recommended in which sulfates are calcined with H_3BO_3 in a current of H, which reduces the SO_3 evolved to H_2S (Pt-asbestos being used as catalyst). In a third process, which is particularly suitable for such S compds. as sulfides (ores), the S is burned in a current of air, and the addn. of H_3BO_3 prevents any S remaining in the residue. The gases of the combustion are conducted over C at $250\text{--}300^\circ$ to convert any escaping SO_3 to SO_2 , and the SO_2 is absorbed in titrated alkali soln. The structural formula of ammonium dithiodioxymolybdate is $(\text{NH}_4\text{O})_2\text{Mo}(:\text{S})_2\text{S}$. C. C. DAVIS

The detection of sulfur and sulfurous acid. AUGUST NOLL. *Papier-Fabr.* 26, Fest- und Auslands-Heft, 59-61 (1928).—The following qual. tests are described: S in any form—heat the powd. substance to redness with S-free Fe in a hard-glass tube, dissolve in HCl, and recognize H_2S by odor, $\text{Pb}(\text{OAc})_2$ test, or (after making alk.) Na nitroprusside test. Sulfite ion in paper or pulp.—Digest sample with distd. H_2O , acidify ext. and test as above. Or, treat the ext. with Zn dust to reduce sulfite to hyposulfite and test the filtrate with indanthrene yellow G, methylene blue, or (after making alk.) Na anthraquinone *n*-sulfonate. With hyposulfite these give the color changes, yellow-blue, blue-colorless, colorless-red, resp. Other reducing substances may interfere in the color tests, and the anthraquinone salt may contain impurities which will give a red color with alkali alone. R. H. DOUGHTY

Accurate method for the determination of iodine in mineral mixtures. M. D. KNAPHEIDE AND ALVIN R. LAMB. *J. Am. Chem. Soc.* 50, 2121-30 (1928).—The addn. of KI or CaI_2 to mineral mixts. to be fed to farm animals has made it necessary for the chemist to know how to det. I in such mixts. Because of adsorption by the charcoal which is usually present, it is impossible to remove the iodide by simple extn. and over 600 analyses were necessary to develop the following method: Melt together 20 g. of NaOH and 10 g. of KNO_3 in a 100-cc. Ni crucible. Cool, add 10 g. of the mineral mixt. and moisten with 5 cc. of satd. NaOH soln. and 10 cc. of 80% alc. Place on a cold, 3-heat hot plate and gradually raise the temp. until finally the contents of the crucible are exposed to the full heat of the plate for about 2 hrs. Then carefully fuse. Extract the melt with water and det. the I content by Kendall's method, eventually titrating free I_2 with $\text{Na}_2\text{S}_2\text{O}_3$. W. T. H.

Iodometric determination of ozone and chlorine. A. JULIARD AND S. SILBERSCHATZ. Brussels Univ. *Bull. soc. chim. Belg.* 37, 205-24 (1928).—A p_H about 7 is required to titrate O_3 exactly by means of KI. The buffer may be boric acid + borax, or NaH_2PO_4 + Na_2HPO_4 . The titration of Cl is not affected by the buffer. Cl and O_3 may be titrated together. A. L. HENNE

Determination of ammonia in sulfonated oils. GEO. LANG. St. Louis College of Pharmacy. *Ind. Eng. Chem.* 20, 693 (1928).—To the emulsion produced in a distg. flask by adding 10-15 g. oil to 50 cc. H_2O , add with shaking 100 cc. 4% NaOH soln. With shaking add 100 cc. 8% CaCl_2 soln. A gummy Ca soap is pptd., and the NH_3 can be distd. into standard acid without foaming. T. S. CARSWELL

Testing brine for presence of ammonia. C. E. ANDERSON. *Power Plant Eng.* 32, 731-2 (1928).—A method is given for sepg. NH_3 from brine, and the use of Nessler's reagent for detg. the presence of NH_3 is described. S. D. POARCH

Methods for estimating hydrogen peroxide. PHILLIP A. BERRY. *Chem. Eng. Mining Rev.* 20, 320-1 (1928); cf. C. A. 22, 2808.—The gasometric method is claimed to be unsatisfactory although no reason is given. The KVO_4 method gives good results under the following conditions. Dil. 20 cc. of peroxide to 200 cc. Of this, dil. 20 cc. to 300 cc., add 25 cc. of 7 N H_2SO_4 and titrate until the excess of KMnO_4 is shown by the color. Sometimes the preservative added to the peroxide causes a fugitive end point. In this case the Kingzett iodometric method is preferable, which otherwise gives results of about the same accuracy as the KMnO_4 method. Take 20 cc. of the diluted peroxide soln., 20 cc. of 3.6 N H_2SO_4 and 2 g. of KI. Shake till the solid has all dissolved, allow to stand 15 min. and titrate with thiosulfate. W. T. H.

Titration of ammonium hydrosulfide with potassium ferricyanide. ANTS LAUR. *Acta Commentationes Univ. Turkuensis [Dorpatensis]* 12A, No. 5, 50; *Chem. Zentr.* 1927, II, 140-1.—Iimori (cf. C. A. 17, 1605) showed that K_2S in alk. soln. could be titrated with $\text{K}_3\text{Fe}(\text{CN})_6$ but the results are lower in dil. soln. A repetition of I.'s expts. shows this to be true but the diln. error is due to the oxidation of S by dissolved O_2 rather than to lack of sensitiveness of the nitroprusside indicator. High results are caused also by too much OH^- , due to its decomposing effect on ferricyanide. Satisfactory results in the analysis of NH_4HS solns. can be obtained if a small vol. of the sulfide soln. is added to sufficient NaOH soln. to make the final soln. 0.075-0.15 N

in NaOH and the total vol. 10-20 cc. Then add 1 drop of 10% NaNOFe(CN)_6 indicator and titrate promptly with 0.1 N $\text{K}_2\text{Fe(CN)}_6$. The titration succeeds in the presence of thiosulfate, polysulfide and small quantities of sulfite. A detailed survey is given of the literature on the detection and detn. of sulfides, hydrosulfides, polysulfides, sulfites, thiosulfates and sulfates in the presence of one another. W. T. H.

Determination of nitrites in nitrocellulose. A. KOHILER AND M. MARQUEYROL. *Mém. des poudres* [1], 23, 19-28(1928).—In a 50-cc. flask, place 4 g. of nitrocellulose and 40 cc. of cold water and digest 24 hrs. at room temp. or 4-5 hrs. at 50°. Make up the vol. to 50 cc., filter and treat 5-cc. portions with the β -naphthylamine-sulfanilic acid Griess reagent. Tables are given showing the relation between the % of nitrites and heat tests at 65° and 110°.

Notes on the analysis of phosphates. A. SANFOURCHE AND FR. BLÉ. *Bull. soc. chim.* 43, 680-3(1928).—The sources of error in the detn. of P_2O_5 in phosphate ores by the citrate method are discussed; although each individual error does not seem serious it is clear that by an accumulation of errors the results may become as much as 1% out of the way. In the official directions it is not specified that sol SiO_2 must be removed. If this is not done the results are likely to be too high, although the error can be reduced by using 50% more of NH_4 citrate than called for in the official directions. Moreover the amt. of citrate added should be increased in the case of rich phosphates. With respect to the concn of NH_4OH in the soln. from which MgNH_4PO_4 is pptd considerable variations are found in procedures followed by different labs. but this does not have much effect on the results. The results are likely to be low if the soln is not properly cooled after adding the Mg reagent and the dil NH_4OH used for washing should be at 18°. The no. of washings does not seem to have much effect if the wash liquid is cold. A slight darkening of the ppt. does not seriously affect the results and the practice of whitening by adding HNO_3 is inadvisable. It is also noted that some labs. are using factors for converting the wt. of P_2O_5 which are based on antiquated at wts.

Acetophenetide as a stabilizer of cupferron solution. FREDERICK G. GERMUTH. *Chemist-Analyst*, 17, No. 3, pp. 3 and 15(1928).—The addn. of 0.05 g. of acetophenetide to 100 cc. of cupferron reagent tends to prevent decompn. of the latter. At the end of 1 month there is only a slight decompn. of the soln.

The antimony-antimony trioxide electrode and its use as a measure of acidity. E. J. ROBERTS AND F. FENWICK. Yale Univ. *J. Am. Chem. Soc.* 50, 2125-47(1928).—The e. m. f. of the $\text{Sb/Sb}_2\text{O}_3$ electrode is shown to depend on (1) the crust character of the oxide used, (2) the presence or absence of air in the electrolyte and (3) the direction by which the state of equilibrium is approached. The best results are obtained with the cubic rather than the orthorhombic oxide. The transition point of these 2 oxides lies at about 570°, the cubic form being the more stable below this temp. Com. Sb_2O_3 is likely to contain enough sulfide to make it necessary to subject it to a drastic purification. In measuring the e. m. f. the electrolyte should be air-free and should be pretreated with a soln. which is more alk. than the one being studied. Under these conditions the e. m. f. is a linear function, with theoretical slope, of the pH of the soln. The difference between it and a H_2 electrode in a soln. of the same acidity is 0.1445 v. at 25°. Equal accuracy can be obtained without excluding air, if the electrode is standardized against 2 solns. of known acidity. Such an electrode is superior to the H_2 electrode as it requires but little attention when once set up. HCl should not be present in concn. greater than 0.16 M, H_3PO_4 greater than 0.15 M and H_2SO_4 in concn. greater than 1 M. Because the behavior of the $\text{Sb/Sb}_2\text{O}_3$ electrode indicated that previously detd. temp. coeffs. applied to the Clark and Lubs buffers were somewhat in error, the pH of certain of these solns. were measured at 25° with the H_2 electrode. In the course of the work it was established that Sb_2O_3 obtained by the hydrolysis of SbCl_3 solns. consists chiefly of orthorhombic crystals. The free energy of formation of cubic Sb_2O_3 at 25° is -150,000 cal and the free energy of transformation of orthorhombic into cubic Sb_2O_3 is -1800 cal. The e. m. f. of the 0.1 N Hg_2Cl_2 electrode was derived in 2 different ways and found to be -0.3341 v.

Gravimetric determination of the thallium radical as thallos iodide. STEPHEN SOULE. *Chemist-Analyst* 17, No. 3, 4(1928).—Believing that more than 1% of KI in excess of the amt. required to form TII is injurious, S. recommends taking a special sample and detg. how much KI can be added before the soln. will give a test with FeCl_3 and CHCl_3 . This procedure, it is claimed, is especially desirable when the Tl content is low. Wash the TII ppt. with 25 cc. of hot water, then with 50 cc. of water satd. with TII, 3 times with alc. and 3 times with ether before drying at 100°.

Two qualitative tests for zinc ions in the presence of manganese, nickel and cobalt

ions. R. RIPAN. *Bul. soc. stiinte Cluj* 4, 80-3(1928).—The 2 tests described depend on the formation of either ZnPy_2I_2 or ZnPy_2Br_2 by adding alkali halide and pyridine in excess. Both are very insol. ppts. and suffice to detect 0.01 mg. of Zn present at a concn. of 5 mg. per 100 cc. of soln. It is proposed to develop a method for the detn. of Zn in the presence of Mn, Ni and Co by means of these reactions. W. T. H.

The use of metallic cyanates as a basis for a new method of separating the members of the third analytical group of cations. (MILE.) R. RIPAN. *Bul. soc. stiinte Cluj* 4, 104-9(1928); cf. C. A. 22, 3104.—Treat the ppt. produced by NH_4OH and $(\text{NH}_4)_2\text{S}$ with a little 10% HCl and some H_2O_2 . Boil gently and filter off residual S. To the soln. add Na_2CO_3 until it is barely acid in reaction, add 1-2 g. of NH_4NO_3 , heat to boiling and ppt. $\text{Fe}(\text{OH})_3$, $\text{Cr}(\text{OH})_3$ and $\text{Al}(\text{OH})_3$ by adding small portions of 2% KCNO soln. Boil a few min. and filter. After washing once, treat the ppt. with 10-12 cc. of boiling N NaOH soln. to dissolve the Na as NaAlO_2 . Make the soln. neutral to litmus and add a few drops of 2 N HCl . Add a little KCNO reagent, and continue boiling. The formation of a ppt. by this treatment indicates the presence of Al. After the removal of the Al from the first ppt., treat the residual $\text{Fe}(\text{OH})_3$ and $\text{Cr}(\text{OH})_3$ with a hot N soln., of NaOH to which 4-6 cc. of Br_2 -aq. has been added. This converts the Cr to yellow chromate anions. In the remainder of the original ppt. $\text{Fe}(\text{OH})_3$ is recognized by its color or by dissolving in dil. HCl and applying the thiocyanate test. In the filtrate from the original pptn. with KCNO detect Mn by treatment with NH_4OH and Br_2 -aq. Filter and test the filtrate for Zn by treatment with KI and pyridine, forming ZnPr_2I_2 . Filter off the Zn ppt. and next test for Co by evap. to dryness, dissolving in 1-2 cc. of water, adding 5-8 cc. of acetone and a few drops of concd. KCNO soln. The formation of a coloration due to $\text{K}_2[\text{Co}(\text{CN})_4]$ is evidence that Co is present. In the same soln., or in another portion of that serving for the Co test, try the dimethylglyoxime test for Ni. W. T. H.

Studies of hydrogen-ion concentration measurements. I. Methods of measurement. CLARKE E. DAVIS AND GLENN M. DAVIDSON. *J. Am. Chem. Soc.* 50, 2053-65 (1928).—Reans and Oakes in 1920 detd. p_{H} values without a potentiometer, using a high-grade condenser, standard cell and ballistic galvanometer. Carhart and Potter have described more recently a similar procedure. This method can be applied to all concn. cells but is especially advantageous for the measurement of the e. m. f. of cells having such a high internal resistance as to render them impossible of measurement by the potentiometer method. It was thought desirable to study carefully the errors of the condenser method. These errors are due to the accumulation of errors on the plates of the condenser, the throw of the galvanometer, humidity and the formula used for the calcn. of the unknown e. m. f. In this paper, the important errors are calcd. and graphs drawn to show the significance of such errors in the titration of H_2SO_4 and of H_3PO_4 with 0.1 N NaOH . In the former case the end point agrees closely with that obtained with the potentiometer but in the latter case the first and second end points are not nearly as clear as with the potentiometer. The accumulative error in the condenser method may amt. to 30-40 mv. in either direction. The results, therefore, seem to indicate that the condenser system of e. m. f. measurements cannot be used where precise work is required, such as in the titration of solns. or in the detn. of equil. consts. W. T. H.

Toxicology of lead and its compounds. IV. Electrolytic detection of lead. P. W. DANCKWORT AND E. JÜRGENS. *Hannover. Arch. Pharm.* 266, 367-74(1928).—An exptl. study shows that Pb can be detected electrolytically in very minute traces even admixed with other metals. In case the cathodic Pb tree formation is masked by other metals, the addn. of HNO_3 causes the anodic sepn. as PbO_2 . The detection of Pb can be effected in the HNO_3 soln. after destruction of org. substance. The growth of Pb crystals is observed under the microscope, the anodic sepn. being carried out in a glass vessel. When a brown coloration of the anode is not directly observable, electrolysis is continued 2 hrs., the Pt wire laid on filter paper and dabbed with Arnold's reagent. V. Quantitative nephelometric determination of lead. *Ibid* 374-82.—It is possible to det. Pb nephelometrically in amts. as small as 0.006 mg. A turbidity standard produced by 0.05 mg. Pb in an AcOH soln. of $\text{K}_2\text{Cr}_2\text{O}_7$ can be used over a period of an hr. without appreciable change in particles or danger of pptn. A series of turbidities is prepd. for purposes of comparison and exclusion. NaOAc and Cu are without influence on the turbidity. Large amts. of Fe, however, make the readings somewhat inconstant. W. O. R.

Determination of organic matter in mixed acid and of carbon in nitrocellulose. CARRIERE AND GUIBERT. *Mém. des poudres* [1], 23, 29-32(1928).—In the flask of a Soxhlet extractor, heat 10 g. of CrO_3 and 120 g. of mixed acid. For C, heat 0.35 g.

of nitrocellulose, 80 g. of 66° Bé H_2SO_4 and 36 g. of 40° Bé nitric acid in the Soxhlet flask. Wash the evolved gas through a pumice-sulfuric acid tube, a permanganate-sulfuric acid tube and collect in a Liebig KOH bulb.

A. J. PHILLIPS

Technical analysis of carbazole. E. SCHWENK AND L. WANKA. *Z. anal. Chem.* **74**, 168-87 (1928).—By a modification of the Kjeldahl method, using CrO_3 and AcOH instead of H_2SO_4 as oxidizer, it is possible to est. the carbazole content with a fair degree of accuracy. Take 0.5-10 g. of material according to whether 50-5% of carbazole is present. To this add 450 cc. of AcOH, heat to boiling and while boiling add 50 cc. of soln. contg. 37 g. CrO_3 , 25 cc. of water and 25 cc. of glacial AcOH. Digest for 0.1 hr. under a reflux condenser and then distil off 400 cc. of coned. AcOH. Dil. with 1 l. of water, add 15 g. of Zn, 300 cc. of 30% NaOH and distil off NH_3 as in the Kjeldahl method.

W. T. H.

Analytical notes concerning vanillin and vanillin sugar. J. PRITZER AND ROB. JUNGKUNZ. *Chem.-Ztg.* **52**, 537 (1928).—The following reagent is most suitable for the detection of vanillin. Dissolve 4.4 g. of KNO_2 or 3.6 g. of NaNO_2 in 100 cc. of cold, satd. HgCl_2 soln. (about 7% HgCl_2) and add 1 cc. of 10% Na_2CO_3 soln. Filter, mix with an equal vol. of the vanillin prepn. and heat 5 min. For the gravimetric detn., treatment with nitrobenzohydrazide is recommended. For the volumetric detn., titration with 0.1 N NaOH, using thymolphthalein as indicator, gives values agreeing closely with the gravimetric method.

W. T. H.

Preparation of polymerization acid. W. H. HAMMOND. *Chemist-Analyst* **17**, No. 3, 14 (1928).—Polymerization acid, contg. 82.39% of SO_3 is used in the analysis of wood and coal-tar distn. products in the presence of hydrocarbons and in testing the purity of turpentine and carbolinum. Weigh a 1-l. reagent bottle. Pour into this bottle the entire contents of a 1-lb. bottle of fuming sulfuric acid. Stopper the bottle and wait until the fumes subside. Then remove a sample to a weighing pipet and transfer the weighed sample to a beaker of water. Det. the acidity and also the acidity of coned. H_2SO_4 . Compute how much of the latter is necessary to bring the fuming acid to the required SO_3 concn. Add about 80% of this quantity of coned. H_2SO_4 , take another sample and check the work before adding the last of the coned. H_2SO_4 .

W. T. H.

A new reaction for the identification of urotropine and of formaldehyde. Rapid method for the analytical differentiation of these two substances in a mixture. MIRCEA V. IONESCU. *Bull. soc. chim.* **43**, 677-80 (1928).—Both urotropine and formaldehyde react with a 5-10% aq. soln. of dimethyldihydroresorcinol to form an insol. cryst. ppt. of methylenebisdimethyldihydroresorcinol. By this reaction 1 g. of urotropine can be detected when dissolved in 50 l. of water. With formaldehyde the reaction is the same as with urotropine except that no NH_3 is liberated. The reaction with HCHO takes place quickly in the cold, whereas the reaction with urotropine is much slower. It is possible, therefore, to test for formaldehyde and urotropine separately, even when both are present. To the cold aq. soln., add an excess of the reagent. If formaldehyde is present the reaction will be complete in about 10 min. After 15 min. filter off the ppt. and heat the filtrate to boiling. Then, if urotropine is present some more of the same ppt. will be formed.

W. T. H.

Action of polyalcohols on periodic acid. Analytical application. I. MALAPRADE. *Bull. soc. chim.* **43**, 683-96 (1928).— $\text{K}_2\text{I}_2\text{O}_8$ in dil. H_2SO_4 soln. reacts with glycol to form KIO_3 and HCHO. One mol. of HIO_4 oxidizes 1 mol. of glycol to 2HCHO. With glycerol and other polyalcohols HCHO and HCO_2H are formed. With 1 mol. of glycerol, 2 mols. of HIO_4 are reduced, 1 mol. of acid and 2 mols. of HCHO are formed. With 1 mol. of erythritol, 3 mols. of HIO_4 are reduced, 2 mols. of acid and 2 of HCHO are formed. With adonitol, 4 mols. of HIO_4 are reduced and with mannitol 5 mols. These reactions can be utilized for the detn. of HIO_4 when mixed with HIO_3 and for the detn. of polyalcohols in pure aq. solns. *Detn. of periodate in the presence of iodate.*—To the acid soln. add KI and titrate the liberated I_2 with thiosulfate. 3I_2 is obtained from iodate and 4I_2 from periodate. In another similar sample, add an excess of mannitol to the acid soln. and after 0.5 hr. add KI and titrate as before. Less thiosulfate will be required because the mannitol has reduced the periodate to iodate. From these 2 titrations both IO_3^- and IO_4^- can be computed. *Detn. of polyalcohol in aq. soln.*—First det. the amt. of thiosulfate required to titrate a portion of periodate after adding KI to the acid soln. Then add the same vol. of acid periodate soln. to a definite vol. of polyalcohol. Wait 2-3 hrs. for the reaction between the alc. and the periodate to complete itself. Then add KI and titrate the liberated I_2 .

Analysis of gases. SOC. ANON. CHARBONS ACTIFS ÉDOUARD URBAIN. Fr. 632,396, July 24, 1926. Changes in the compn. of a mixt. of gases or vapors are detected by the automatic recording of the absorption spectrum of light after passing through the gas.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

Some minerals of the Kuban metalliferous region, Caucasus. P. I. LEBEDEV. *Bull. acad. sci. union rep. soviet. serial*. 1927, No. 12-14, 953-66 — Dolomite, barite and sphalerite occur in veins. Two samples of each were analyzed with the resp. results: SiO_2 0.22, 0.50, CaCO_3 57.71, 53.39, MgCO_3 35.59, 42.29, FeCO_3 6.28, 3.85%; sp. gr. 3.077, 2.861. BaSO_4 97.96, 97.17, CaSO_4 1.02, 0.0, SrSO_4 0.33, 2.06, MgSO_4 0.50, 0.0, loss on ignition 0.30, 0.0%. ZnS 86.66, 83.78, FeS 11.69, 15.82, CdS 1.39, 0.06, PbS 0.26, 0.34%; sp. gr. 4.107, 4.075.

BERNARD NELSON

Reniphorite, a new mineral from the Yunosawa mine, Province of Mutsu, Japan. KEIKICHI KAWAI. *Jap. J. Geol.* 3, No. 3-4; *Chem. Zentr.* 1926, II, 3028 — The mineral, which occurs with barite, has d. 6.451 and the compn. $5\text{PbS} \cdot \text{As}_2\text{S}_3$. It is thus an analog of geonorite, $5\text{PbS} \cdot \text{Sb}_2\text{S}_3$.

C. C. DAVIS

Iozite, an important mineral of the lava of young volcanoes. ALB. BRUN. *Schweiz. mineral. petrog. Mitt.* 4, 355-6(1924); *Chem. Zentr.* 1926, II, 3031. — Iozite (FeO) occurs frequently in lavas rich in Fe. It seps. with feldspars, forming rectangular opaque granules ($< 10\mu$ in size), and comprises 0-50% of the Fe content of the lava.

C. C. DAVIS

Preliminary communication on a study of the structural change of the solid solution of moonstone (Japan). SH. KOZU AND KENICHI WADA. *J. Geol. Soc. Tokyo* 30, 342-56(1923); *Chem. Zentr.* 1926, II, 3030. — X-ray photographs of Ceylon moonstone showed that at 400° it consists of 2 solid phases, one of which is rich in K, the other in Na. At 500° these 2 phases blend, at 700° there is a sudden pronounced structural change; and at 1650° the 2 phases form a homogeneous solid soln. With the structural change the optical axial angle increases. In moonstone from Korea, blending of the 2 phases is complete at 650° . The shimmer of Ceylon moonstone disappeared at 1100° , that of Korea moonstone at 700° .

C. C. DAVIS

The pyroxenes of Campiglia Marittima, Tuscany. P. ALOISI. *Mem. accad. Lincei* [6], 2, 2-15(1926); *Chem. Zentr.* 1926, I, 256. — There are 3 types: (1) dark green or brown, with long thick fibers; (2) light gray-green to brown-yellow, with fine fibers and (3) reddish, in granular or foliated masses. They gave, resp.: H_2O —, 0.22, 0.24, —; $\text{H}_2\text{O} +$, 0.46, 0.28, —; SiO_2 , 47.16, 49.28, 51.84; Al_2O_3 , 0.72, 0.82, 0.75; Fe_2O_3 , 6.10, 0.19, 0.45; FeO , 19.50, 1.25, 1.21; MnO , 3.75, 27.60, 33.85; CaO , 22.16, 20.32, 9.33; MgO , 0.66, 0.72, 1.37. Type 1 is of the compn. of hedenbergite contg. Mn, and has the usual optical properties of such pyroxenes, often with twin formation as in augite. It is accompanied by granules of quartz, magnetite, calcite, and perhaps also zoisite and clinozoisite. The optical properties of type (2), a *bustamite*, approach those of hedenbergite. This type is accompanied by quartz. The compn. of type (3) resembles a *rhodonite* contg. Ca. This type has optical monoclinic or pseudomonoclinic symmetry, and is accompanied by quartz and calcite. Transition forms between types (2) and (3) exist. The optical properties of the *bustamite* and *rhodonite* are notably different from those of other pyroxenes of similar compn. There is no evident relation between the optical properties and chem. compn. of pyroxenes contg. Mn.

C. C. DAVIS

Crystallographic study of some crystals of Brazilian euclase. MARIA PIAZZA. Univ. Rome. *Mem. accad. Lincei* [6], 2, 18-29(1926); *Chem. Zentr.* 1927, I, 51. — In pale yellow, greenish yellow or blue-green crystals of Brazilian euclase were frequently observed inclusions (apparently mica or chlorite) and natural etch figures, prevailing in the direction of the vertical axis. Their arrangement confirmed the classification of the mineral as monoclinic prismatic. The crystallographic data are recorded in detail.

C. C. DAVIS

A microchemical method applied to stellerite. SR. J. THUGUTT. *Arch. lab. min.*

Soc. des Sciences de Varsovie 1, 34-6(1925); *Chem. Zentr.* 1927, I, 1047.—After dehydration at 140°, stellerite becomes yellow-red with AgNO_3 and K_2CrO_4 , whereas stilbite similarly treated remains colorless. C. C. DAVIS

Wolchonskoite. L. V. PUSTOVALOV. *Trans. Inst. Econ. Mineral. Met. (Moscow)* 1928, No. 36, 1-57; cf. *C. A.* 8, 41.—It has hitherto been thought that wolchonskoite is a rare mineral, but P. finds that it is, on the contrary, very widely distributed in north-eastern European Russia. The samples hitherto described do not represent the unaltered original material, but only an air-dried modification. Freshly mined wolchonskoite, which is always moist, does not disintegrate in water into small pieces like the mineral which has become dry; it possesses different structure and properties. The genesis of wolchonskoite and its chem. nature remain as yet but little known. BERNARD NELSON

The problem of the chemical formula of apatite. H. HAUSEN. *Finska Kemist-samfundets Medd.* 35, 9-18; *Chem. Zentr.* 1927, I, 1811.—A preliminary communication. The chem. compn. of apatite can be expressed in a composite formula, which contains, besides the double salt $3\text{Ca}_3(\text{PO}_4)_2 \cdot \text{Ca}(\text{F}, \text{Cl})_2$, the isomorphous compd. $3\text{Ca}_3(\text{PO}_4)_2 \cdot \text{Na}(\text{F}, \text{Cl})$ in variable proportions. In formulating its compn. it is essential to know the relation between the F deficiency on the one hand and the alkali content on the other. C. C. DAVIS

The nature of the lead in vanadinite of the Tjuja Muyun radium mine, Ferghana. K. NENADKEVICH. *Compt. rend. acad. sci. U. R. S. S.* 1926, 56-8; *Chem. Zentr.* 1927, I, 1811-2; cf. *Bull. acad. Leningrad* [6], 1926, 767.—The Pb in the vanadinite has d, 11.349, and its at. wt. is 207.16, which indicates that it is ordinary Pb, not formed from U. C. C. DAVIS

Zoning of mineral deposits in British Columbia. GEORGE HANSON. *Trans. Roy. Soc. Can.* 21, IV, 119-26(1928).—A review of the mineralogical maps of B. C. indicates that different metals and ore minerals occur at different distances from their common igneous source. The minerals in an area of 400 sq. miles in the Zymoetz River area east of Prince Rupert have a distinctly zonal arrangement. High-temp. minerals such as scheelite, molybdenite and Au-quartz veins lie in the tongue of the batholith, while low-temp. minerals are found in the outer zone. The minerals found in the area are scheelite, molybdenite, Au, chalcopyrite, pyrite, bornite, sphalerite, galena, tetrahedrite and some Ag minerals. Across the zones a gradation is evident from Au through Cu to Ag-Pb-Zn deposits. The metals probably arose from a source directly below the deposits and the apparent zoning is due to the dip of the source rock. From a study of the relationship of mineral deposits to possible sources of origin, H. concludes that ore deposits have their origin in an irregular tabular zone not much more than 1000 feet thick in the uppermost part of the parent magma. The lack of mineralization in certain areas is attributed to the absence of metals in the source and the nature of the country rock. The location of the zone of origin of ore deposits should be the guide in searching for new ones. Metal zoning is to be preferred to mineral zoning. J. W. SHIPLEY

U. S. S. R. resources in mineral raw materials, their geographical distribution and exploitation in chemical industry. A. G. FERSMAN. First All-Russian Conference on Problems of Chem. Industry. *J. Chem. Ind. (Moscow)* 4, 277-82(1927).—Estimates of the total Russian supplies in mineral chem. raw materials are as follows: *Very considerable:* salt, lime, chalk, quartz, Glauber salt, gypsum; *considerable:* P, pyrite, S, kaolin, refractory clays, magnesite, K salts, Mg salts, fluorite, SrSO_4 , BaSO_4 , Cr compds., Be compds., Se; *moderate:* bauxite, feldspar, mineral dyestuffs, dolomite, Ti compds. (ilmenite and titanomagnetite), Br and I salts, As, Ra; *small:* soda, alunite, Th, Zr, Bi, V; *poor or lacking:* saltpeter, B. Many of these resources are almost untapped. The *White Sea-Leningrad region* is rich in bauxite, feldspar, quartz materials, barite, mineral dyestuffs, celestite, apatite, dolomite, gypsum, refractory clays. Hydroenergy and peat being abundant in this region the following chem. industries are coned. there: manuf. of ceramics, of refractory products, of Al, of alundum, of mineral dyestuffs, of P and of fine chemicals. The *Central-Industrial and Volga region* contains clays, gypsum, dolomite, salt, phosphorites, brown coal. The presence of big consumption centers and of competent workers led to the development in this region of a no. of chem. industries, particularly glass and ceramics. The *Donetz-Ural region* is rich in coal, kaolin, lime, salt, chalk, quartz materials, feldspar, phosphorite, mineral dyestuffs, etc. This region would be well adapted to a development of a powerful chem. industry, if it were not for the lack of H_2SO_4 . The *Black Sea-Caspian Sea region* contains salt, mineral oil, Glauber salt, S, Br, I, Mg. *Caucasian-Transcaucasian region:* mineral oils, barite, pyrite, alunite, As, salt, Glauber salt, S, acid-resisting materials, lime, Mn, Co, Cr, Zn, Cd. This region undoubtedly has an enormous future. *Kama-Ural*

region: pyrite, K salts, phosphorites, salt, kaolin, lime, quartz, feldspar, mineral dyestuffs, talc, magnesite, As, dolomite, nephelite, Se, Ti, Cr, Ba, Li, Zn. An important chem. industry should be developed in this region. **Mid-Asiatic region:** mineral oils, ozocerite, salt, Glauber salt, S, barite, celestite, fluorite, V, U, Ra, Sb, Hg. **Kirghiz-Alai region:** salt, Glauber salt, barite, pyrite, refractories, Zn, Mo, Pb, Cu. **Kuznetsk-Minusinsk region:** coal, salt, pyrite, barite, fluorite, feldspar. **Transbaikal region:** Glauber salt, soda, fluorite, As, W, Bi, Sn, Mo, Zn, Pb, rare earths, Be, Li. Chem. development is just beginning.

BERNARD NELSON

Natural productive strength of Russia. S. LICHAREVA. **Strontianite and celestite**, No. 30a; **Useful fossil materials**, 4; **Copper**, No. 7, 1-183; **Silver, lead, zinc, gold**, No. 8, 1-118, 68 pp.; *Chem. Zentr.* 1927, I, 1144.—The catalog of the strontianite and celestite deposits of Russia includes analytical data on these minerals of the most varied origin and formation. Strontianite always contains more or less CaO and BaO, and celestite always CaO and SrO.

C. C. DAVIS

Rare-metal deposits in Brazil. HENRIQUE G. THUT. *Chimica industria* 1, 349-54 (1926); 2, 383-4, 403-4 (1927).—**Monazite sands.**—The monazite deposits of Brazil are the largest in the world; they extend from the state of Bahia to the state of Rio de Janeiro. Compn.: Ce 62%, Th 1.5-15%, Y 1-3%, La 2.5%, Fe 2.5%, Al 3%. The sands are coned on Wilfleys and on Humboldt magnetic separators. Th is extd. as sulfate from monazite and thorite by decompn. with H_2SO_4 . Ce is found assoc. with La, Y and Th in samarskite, euxenite and monazite. The powd. mineral is digested with hot H_2SO_4 and pptd. as double sulfate with K_2SO_4 , the metals of the Y group remaining in soln. Y combined in gadolinite, xenotime and in monazite sand; La in monazite sands, cerite, allanite and lanthanite. La oxide is easily reduced by Na or K, or by electrolysis of the double Na chloride. Ta and Nb combined in samarskite (40% Ch_2O_6 , 14% Ta_2O_5), tantalite and columbite, at Ramalhetes, Peconha (Minas). Nb is obtained from the oxide by a reduction with Al; Ta from the fluoride by K. V is found in many places as vanadinite; it is extd. from a $NaOH-Na_2CO_3$ fusion with H_2SO_4 . Er is found combined in xenotime near Diamantina and Tripuhi (Ouro Preto). The mineral is decomposed by HF and the insol. Er is sepd. by filtration. Notes on history, properties, compds. and uses are given for each metal.

R. D. BUMBACHER

Gold and silver deposits in the Omui gold mine. CHOZO IWASAKI. *Japan. J. Geol.* 52, No. 3-4, 13-8 (1924). *Chem. Zentr.* 1927, I, 1143-4.—1. holds that during a liparite eruption, colloidal solns. of Au and Ag sulfides and SiO_2 penetrated the rock veins and remained there. Then began a concn. of the noble metals in the colloids which, like breccia, were sealed by the remaining crystd. silicates. Chlorination followed, with formation of cerargyrite and argentite and finally disintegration. In the last 2 yrs., 2500 tons of ore with 0.0024% Au and 0.036% Ag were obtained from one vein alone.

C. C. DAVIS

Mines of gold, silver and copper ore at Matrabanya [Hungary]. A. VITÁLIS. *Földtani Kozlony* 56, 172-83 (1927).—A geological description. Analyses of a few ores are given.

A. L. HENNE

Magnetic nickel pyrite deposits of the southern Black Forest in the St. Blasien district. K. SAUER. *Ber. Freiburger Geol.* 8, 78-85 (1920). *Chem. Zentr.* 1927, I, 1144.—A description of the deposits, which contain an av. of 0.25% Ni + Co and 0.3% Cu.

C. C. DAVIS

Note on the existence of a bauxite bed in Shan-Tung, China. KYUKICHI WATANABE. *Japan J. Geol.* 3, No. 3-4, 87-90; *Chem. Zentr.* 1927, I, 1144.—In the coal fields of Shantung there is a deposit, extending over 100 km., and varying from white to almost black, which by microscopic examn. appears to be homogeneous with only a few crystal formations. Analysis showed 55% Al, a high content of combined H_2O and a little SiO_2 . In the darker parts the Al content is lower than in the lighter parts.

C. C. DAVIS

Base exchange and the formation of coal. E. MCKENZIE TAYLOR. *Nature* 121, 789-90 (1928); cf. *C. A.* 22, 371.—An examn. of the roofs of bituminous coal seams of the Jurassic, Cretaceous and Tertiary ages proved that these roofs like those of the Carboniferous age have undergone base exchange and hydrolysis. The final stage in coal formation appears to have been the bacterial decompn. of accumulated plant material under alk. anaerobic conditions. An expt. was arranged by placing a mixt. of sand and fat at the bottom of a beaker and inoculating this layer with soil suspension. A roof contg. hydrolyzing Na clay was deposited on the sand-fat layer and the whole was covered with water and was incubated at 30°. The fat was hydrolyzed, the resulting glycerol being converted to CH_4 and the aliphatic acid being reduced to the corresponding paraffin. These results have a bearing on the formation of petroleum as well as coal.

L. W. RIGGS

Tables for the calculation of rock analyses. D. J. MAHONY. *Bull. Geol. Survey Vict.* 1927, 51; *Australian Sci. Abstracts* 7, 5.—Three sets of tables are given, based on accurate at. wts. The first 2 tables are for mol. proportions and percentage wts. of mol. proportions of normative minerals. These tables are set out in a new form which greatly shortens them, does away with interpolation and gives accurate results to the second decimal place. The third set of tables enables practically all the common rock-forming minerals to be calcd. directly from analysis and may be used for taking out both norm and mode. H. G.

Minerals of the Soogoor mountain range. E. A. KUZNETZOV. *Trans. Inst. Econ. Mineral. Met. (Moscow)* 1928, No. 37, 1-53.—The Soogoor range, which is a prolongation of Mount Karabash, is composed of serpentines and pyroxenites intersected with bands of porphyrite tuffs and tuff schists. Chem. and mineralogical analyses are given of the *serpentines*, *pyroxenites* and rocks derived from them by partial metamorphism and erosion. BERNARD NELSON

Metamorphized gabbrodiorite of Klokocna. J. KRATOCHVIL and V. VISELY. *Rozpravy. Ces. Akad.* 31, Kl. II, No. 27, 1922; *Chem. Zentr.* 1926, II, 3027 + C. C. DAVIS

Petrographic study of the dark sands of the north shore of the Sea of Azov. P. CHIRVINSKII. *Verh. Russ. Miner. Ges.* 54, 159-72 (1925); *Chem. Zentr.* 1927, I, 1568.—The sand between Novonikolaevskaya and the Mins-Limans shore consists, as indicated by a representative analysis of quartz 48.97, magnetite 25.19, staurolite 13.40, orthite 3.83, garnet 3.00, sillimanite 1.25, cyanite 0.62% and other minerals. The minerals of this Quarternary sand must originate from granite, gneiss and cryst. schist of south Russia. C. C. DAVIS

Nature of clay and its significance in the weathering cycle. G. W. ROBINSON. *Nature* 121, 903-4 (1928).—The primary residual product of the chem. weathering of silicates is a mixt. of kaolinite and notronite or of hydrated silicates having the same silica-sesquioxide ratio, namely, 2. Variations from this ratio may occur as a result of the differentiation consequent on soil profile development, leading in humid temperate climates to the production of a more siliceous (a) horizon and a less siliceous (b) horizon, and in humid tropical climates to the formation of laterite. Enrichment of the clay complex in silica takes place in estuarine and other littoral sediments in consequence of the concomitant pptn. of the silicic acid present in river waters. J. W. RIGGS

Chemical action in the desert. G. STEINMANN. *Sitz-Ber. Niederrhein. Ges. Natur.-u. Heilkunde Bonn* 1924, 8-12; *Chem. Zentr.* 1927, I, 257.—In the desert regions of Atacama, the occurrence of abundant quantities of halides of the heavy metals is worthy of note. The origin of borates is doubtless volcanic, and probably Chili salt-peter originated in a similar way. The halides accompanying the ore veins contain large quantities of I, Br and Cl compds., enriched with Ag, Cu and Pb. The transformation of the S ores to halides as well as the oxidation of the halides and of the NH_3 are to be regarded as special effects resulting from chem. reactions characteristic of the desert climate. C. C. DAVIS

Chemical weathering in the Egyptian desert. E. BLANCK, S. PASSARGE, A. RIESER and F. HEIDE. *Hamburg, Univ. Abh. Gebiet Auslandskunde* 17, Reihe C, *Naturwissenschaften* 6, 110 pp. (1925); *Chem. Zentr.* 1927, I, 257.—The Egyptian deserts are regions of active chem. disintegration. Everywhere that rock is covered with a black-brown protective crust, a diluvial surface may be present. The formation of a desert crust is the most important chem. transformation. The weathering of the individual rocks is considerably greater than has been heretofore assumed. C. C. DAVIS

A few observations on the Island of Vulcano. A. ROCCATI. *Boll. soc. geol. ital.* 44, II, 135-9 (1925); *Chem. Zentr.* 1927, I, 1569.—Up to the present time NH_4Cl and B_2O_3 have been considered normal products of the fumaroles of the Island of Vulcano. This idea is however erroneous, for the most frequent efflorescent products of the soil are $\text{Fe}_2(\text{SO}_4)_3$ and $\text{Al}_2(\text{SO}_4)_3$. The eruption of a S fumarole was observed. The temp. of the S which emanated was 98° , that of the steam 104° . The activity lasted about one month, and 10 tons of S were given off. Another fumarole yielded in the same length of time 30 tons of S at 106° . In this fumarole a sudden rise of temp. was accompanied by the escape of HF. Because of the water also discharged, SiF_4 was formed, and gelatinous SiO_2 at cracks and fissures. C. C. DAVIS

Lead and articles manufactured from it. BRENTHEL. *Chem.-Ztg.* 52, 169-70, 190 2, 250 2(1928).—A lecture outlining the metallurgy, properties and uses of Pb and its alloys. Lead sheet, pipe, valves, pumps, cable covering and app. for use in the chem. industry are given special consideration. W. C. EBAUGH

Gold, silver, copper, lead and zinc in Idaho and Washington in 1926. C. N. GERRY. *Bur. Mines, Mineral Resources U. S.* 1926, Pt 1, 415-70 (preprint No. 20, published June 23, 1928). E. H.

Flotation practice at the Sullivan mill. C. T. OUGHTRED. *Can. Mining Met. Bull.* No 194, 804 16(1928).—A detailed description, with data and flow sheets. A. BUTTS

Milling Baboquivari ore. EDMUND S. LEAVER AND JESSE A. WOLF. *Bur. Mines, Repts. of Investigations* No 2874, 2 pp(1928).—An analysis of this ore shows SiO_2 90.10, Fe_2O_3 5.30, Al_2O_3 1.64, CaO 0.20, MnO 1.20, S 0.04%, Ag 4.23 oz. per ton and Au 0.275. A flotation mill does not conc. precious metals satisfactorily. In lab. grinding to 65 mesh and floating with xanthate or standard flotation oils + Na_2S and polysulfide gave concn. of 32% of the Ag and 80% of the Au. This about equals plant practice. Flotation does not conc. oxidized forms of Mn satisfactorily. Plain cyanide on original ore exts. practically all Au but only $\frac{1}{3}$ of the Ag. A preliminary deoxidizing roast, with producer gas or powdered coal, gives a calcine from which cyanide dissolves about 90% of the Au and 75% of the Ag. This is the Clevenger-Caron process described in *C. A.* 19, 2624. Preliminary treatment with SO_2 by burning pyrite or S and passing this gas into the pulp until all Mn is dissolved or changed in form best prepares the ore for cyanidation. Neither Au nor Ag is dissolved by this acid treatment. The washed residue gives max. cyanide solution of Au and Ag with min. loss of cyanide. H. C. PARISH

Cyanidation test on high-grade gold ore from the Columbia mine. H. D. WILSON. *Black Hills Eng.* 16, 205-13(1928).—The best recovery with extra-fine grinding followed by amalgamation and cyanidation was 74%. Roasting at 500-600° till sweet resulted in over 90% recovery. Photomicrographs are reproduced. E. G. R. A.

Microscopic study of an ore as an aid in copper leaching. R. E. HEAD. *Eng. Mining J.* 126, 13-5(1928).—Ore from the Castle Dome ore body of the Pinto Valley Mining Co., near Miami, Ariz., was studied chemically and microscopically. In addn. to showing the nature of the metal-bearing and gang minerals present, the microscopic examn. indicated that the extent and nature of the fracturing, together with the compn. and mode of occurrence of the Cu-sulfides in the ore (chalcocite, covellite and chalcopyrite), are important considerations in conducting leaching operations and emphasized the value of microscopic study in procuring data not obtainable by chem. means. W. C. EBAUGH

Observations on the Inspiration leaching plant. E. H. ROBIE. *Eng. Mining J.* 125, 971-4(1928).—A discussion of metallurgical operations at Miami Copper Co. and Inspiration Consolidate Copper Co. plants, with photographs. H. C. PARISH

Bromocyanide treatment of telluride concentrate at Wright-Hargreaves. J. T. WILLEY. *Eng. Mining J.* 126, 16-7(1928).—Detailed directions are given for treating a part of the mill concentrates with "Dow's mining salts" (a mixt. of NaBr and NaBrO_3), "Cassel's cyanide" and H_2SO_4 . To make 1 lb. of bromocyanide, 521 g. Dow's salts per 1500 cc. water, 207 g. Cassel's cyanide per 1500 cc. water and 484 g. H_2SO_4 (66° Bé.) per 4500 cc. water, are mixed. A 20-lb. lot of bromocyanide mixt. is prepd. at once by running the 2 salt solns. into the acid. [Danger from HCN.—Abstr.] The soln. is then discharged into an agitator contg. 15 tons slime and 15 tons soln. Subsequent similar additions of 20- and 10-lb. portions of bromocyanide are made, thus

reducing the Au to a dollar in the tailings. Approx. 70 lbs. of bromocyanide are needed per charge, and about 6 hrs' treatment is sufficient. The entire charge of concentrate and soln. in the tank is then added to the secondary thickeners of the mill circuit. Extns. of 98% Au are claimed.

W. C. EBAUGH

Some constituents of basic open-hearth slag. J. M. FERGUSON. *Roy. Tech. Coll. Met. Club J.* 1927-8, No. 6, 9-18.—Tricalcic silicate, tricalcic ferrite and a magnetic constituent analyzing 8% SiO₂, 4.79% Al₂O₃, 32.04% Fe₂O₃, 4.86% FeO, 13.65% MnO, 32.20% CaO and 5% MgO, were isolated from basic open-hearth steel finishing slags, chemically analyzed, examd. in reflected and oblique light, and observations made of their optical behavior in thin sections by means of polarized light. Some aspects of the occurrence of these constituents in working slags are considered. Thirteen references are included.

DOWNES SCHAAF

Mining, milling and smelting at Superior, Arizona. E. H. ROBBE. *Eng. Mining J.* 125, 932-5(1928).—A short description is given of the mine, mill and smelter of the Magma Copper Company as well as the Belmont plant located at Superior, Wis. Analyses of mill feed and products of the Magma Company are given as follows:

	Cu	Ag	Au	Fe	CaO	Al ₂ O ₃	SiO ₂	'S
Mill feed	5.38	2.73	0.026	13.3	1.0	8.0	52.5	12.7
Table concentrate	13.60	8.51	0.086	31.7	0.7	2.2	10.4	13.0
Flotation feed	3.60	1.87	0.01	8.9	1.0	8.2	62.1	8.4
Flotation concentrate	16.15	8.29	0.085	25.6	0.8	3.4	17.9	28.7
Final tailings	0.168	0.12	Trace	5.5	1.3	10.6	73.6	2.2

Refractoriness of molding sand. J. F. McMAHON. *Investigations in Ceramics and Road Materials, Dept. of Mines, Can.*, No. 690, 9-24(1928).—Conditions which prevail at the point of contact of sand molds with molten metals and which affect refractoriness are: (1) Atm.—highly reducing, (2) slag action—slight, (3) heat application—sudden, (4) imposed load—lbs to ton per sq ft, (5) temp.—up to 1670°. Some factors affecting the refractoriness of molding sand are: (1) Mineral and chem. constituents of the sand: (a) the granular material, and (b) the bonding clay; and (2) fineness of grain. Reactions that may take place upon heating a molding sand are: (1) Removal of mechanically held and chemically combined water, (2) decomposition of carbonates, (3) shrinkage of bond, (4) vitrification of bond, (5) corrosion of accessory

materials and (6) corrosion of sand grains. Tests for molding sand are: (1) softening point detn., (2) draw-trial test—crushing strength of fired molds, and (3) Saeger's test. In Saeger's test a sample of molding sand in the shape of a bar is heated locally by an elec. heated Pt ribbon and the temp. noted at which the sand sinters and adheres to the ribbon. L. B. MILLER

Brass in engineering: Failures and remedies. W. N. JONES. *Eng. News-Record* 101, 161-4(1928).—A detailed description and discussion of failures of brass and bronze strainer plates and bolts in the Minneapolis, Minn., rapid sand filters, together with an outline of similar experiences at other plants. The studies carried out indicated that the failures were due to internal stress set up by cold working of the metal and subsequent corrosion by external agencies, such as CO₂. Annealing the metal was found to be an effective remedy, 1300° F. being the critical temp. Monel metal was found satisfactory. R. E. THOMPSON

Rail failure statistics for 1926. W. C. BARNES. *Am. Ry. Eng. Assoc. Proc.* 29, 562-72(1928).

Transverse fissure statistics. W. C. BARNES. *Am. Ry. Eng. Assoc. Proc.* 29, 573-9(1928).

Malleable iron. F. H. HURREN. *Iron and Steel of Canada* 11, 196-9(1928).—The time of annealing and the effect of different concn. of Si, C, S, P, Mn, Ni and Cr in whiteheart malleable iron castings are briefly considered. Methods are suggested for overcoming or minimizing the troubles due to distortion, hard spots and cracks. D. S.

Carbon-silicon ratio determines physical qualities of malleable. L. E. GILMORE. *Foundry* 56, 529-31(1928).—The relative proportion of Si and C in white-iron castings, is the most important factor in controlling the amt. of combined C in them. The combination of greatest tensile strength and ductility in malleable castings is obtained with low C and high Si. In works practice, a low C of 2.20-2.40% and a correspondingly high Si of 0.90-1.00% have given very good results over a period of two years. To insure heats being tapped with the desired Si and C, preliminary chem. analyses should be made before tapping, or in lieu of lab. control, test bars should be cast and cooled under standardized conditions so that their fracture when broken will indicate the condition of the heat. DOWNS SCHAAF

A comparison of whiteheart and blackheart malleable cast irons. A. E. PEACE. *Proc. Inst. Brit. Foundrymen* 20, 327-49(1926-7).—The essential differences in method of manuf., chem. compn., melting, casting, annealing, structure, properties and applications of whiteheart and blackheart malleable castings are described. D. S.

The heat-treatment and growth of cast iron. J. W. DONALDSON. *Proc. Inst. Brit. Foundrymen* 20, 513-43(1926-7).—Heat-treatment tests were carried out on an ordinary general engineering iron, a cylinder iron and two irons made by the Perlit process. The tests were divided into two groups, one dealing with carbide decompn., strength and hardness, and the other with carbide decompn. alone, and the min. temp. required to produce it. The combined C content, tensile strength and Brinell hardness figure were detd. after each 40 hrs. heating, the temp. of the heat-treatments ranging from 200° to 550°. The results of the various tests are set forth in tables, graphs, and photomicrographs, and the following conclusions are made: (1) Carbide decompn. accompanied by graphite deposition takes place in gray cast iron when subjected to low-temp. heat-treatment. (2) Stability of the carbide is influenced by the Si content, and also by the initial combined C content. (3) Stability is also influenced by the temp. and the duration of heat-treatment; over 200° the rate of change varies with the temp. and the nature of the iron. (4) Carbide decompn. also affects the mech. properties of gray cast iron according to the condition and duration of heat-treatment. (5) Growth and vol. changes are in some ways related to carbide decompn., but not wholly explained by it. DOWNS SCHAAF

The strength of cast iron. J. E. FLETCHER. *Proc. Inst. Brit. Foundrymen* 20, 188-232(1926-7).—The mean results of many tests made on groups of iron castings, indicate that the tensile and transverse strengths of cast iron are distinctly related to the sum of the total C and Si contents. The influence of total C, Si, Mn and P, have been correlated with Brinell hardness figures, and again the sum of the total C and Si contents prove to be of great value. The importance of the relationship between the tensile and transverse strength values is stressed, since this factor is related to the deflection, to the sum of the total C and Si contents and to the proportion of C to Si in that sum. DOWNS SCHAAF

The effect of nickel and chromium on the strength properties of gray cast iron. E. PIWOWARSKY. *Proc. Inst. Brit. Foundrymen* 20, 166-87(1926-7).—Very high mech. strengths were obtained by causing cast Fe having a gray to mottled charge

to solidify at first white to mottled by accelerated cooling, and graphitizing it only by subsequent annealing. A still further increase of tensile properties of from 10 to 30% was obtained by the addn. of Ni or of Ni and Cr. Small castings with a wall thickness of 35 mm. were completely graphitized in 10 minutes by immersing them in a salt bath at a temp. of 925° to 950°.

DOWNES SCHAAP

The critical points and martensitic quenching of cast iron containing nickel with and without chromium. LEON GUILLET, GALIBOURG AND BALLAY. *Compt. rend.* 187, 14-7 (1928).—Martensitic quenching is defined as rapid cooling through the crit. point, resulting in a structure of martensite. Twenty samples of cast Fe contg. 3.2 to 3.4% C, 0.9% P, 0.21 to 0.63% Mn, 0.74 to 2.11% Si, 0 to 4% Ni and 0 to 0.7% Cr were prepd. and heat-treated carefully in similar ways. Some specimens were cooled slowly in the furnace at 8° to 10° per min. from 950° to 450°; others were cooled in a current of air at 250° per min. The transformation temp. is tabulated for each sample under different conditions of heat treatment and also the hardness change as compared to the as-cast condition. Si raised the transformation temp. and the crit. rate of martensitic quenching. Mn lowered the transformation temp. slightly and the crit. rate of quenching distinctly, and also increased the hardness after quenching. Ni lowered the transformation temp. and the crit. rate of quenching, facilitating martensitic quenching as well as graphitization. Cr lowered the crit. rate of quenching and increased the depth of martensite formation. Industrially useful cast Fe contg. Ni or Ni and Cr may be either machinable as cast and capable of hardening by heat-treatment around 900°, or self-hardening as cast but machinable after brief annealing at 650°.

GLO. F. COMSTOCK

The influence of sulfur in cast iron. J. E. HURST. *Proc. Inst. Brit. Foundrymen* 20, 497-512 (1926-7).—The theoretical reasoning for the modern view of the influence of S on cast iron is given at some length. It includes that in the presence of sufficient Mn, at least in the ratio of 3:1 in low-silicon iron, the S is converted to MnS, in which form it is harmless up to appreciable amts., and even in the absence of sufficient Mn the presence of a rather high concn. of FeS will not have any serious effect with higher Si and total C contents, particularly when the rate of cooling is comparatively slow.

DOWNES SCHAAP

Nitrogen in technical iron. V. N. SVETCHNIKOFF. *Rev. métal.* 25, 212-21, 289-97 (1928).—The investigation, the results of which are given in detail, showed that N is liable to segregation in steel, segregation being greatest in mild steel and the increase in N content in the segregation zones reaching at times an increase of 100% over the N content in zones which do not exhibit segregation. The character of the N segregation is similar to that of P segregation. The following are the factors affecting the N content of Bessemer steel: Si and Mn contents of the Fe, temp. of the metal, time of blowing and pressure of the blast. Increase in the pressure of the blast is one of the factors favoring most the increase in N content of the metal.

A. P.-C

Effect of mass on heat treatment of nickel steel. W. ROSENTHAIN, R. G. BATSON AND N. P. TUCKER. *J. Iron and Steel Inst.* 116, 385-417, 418-53; *Science Abstracts* 31B, 184-5.—This investigation was undertaken to ascertain the relationship between mech. properties and microstructure and the size of the heat-treated pieces. The exptl. work was carried out on bars 2, 4, 7 and 10 in diam. Conclusion: Properties that can be obtained by hardening and tempering small specimens cannot be obtained by similar treatment of large masses.

H. G.

Heat-resisting steels. ROBERT HADFIELD AND R. J. SARJANT. *Fuel Econ. Rev.* 7, 72-80 (1928).—Heat resisting steels consist of solid solns. of the austenitic type and of simple grain; they produce a very small film of scale, adherent, dense and refractory, when heated. These steels run 10-30% Cr, 7-40% Ni, 50-70% Fe, usually with small addns. of Si, W or Mo. The normal tensile strength test is inadequate for heat-resisting steels. "Limiting creep stresses" are far better criteria, especially at high temps. Ordinary steel is practically valueless for supporting loads above 500°, besides scaling badly. Heat-resisting steel has a strength 10 times that of cast iron, resists the action of sulphurous gases, and is superior as regards resistance to scaling and creep stress at the highest practical temps. It is also machined easily, both in castings and forgings and welds readily by the oxyacetylene or electric processes. Their superiority in ultimate cost is indicated by bottle molds; when made of cast iron they can be used perhaps 50,000 times, but if heat-resisting steel is used, several million operations can be carried out.

Alloys affect properties. EDMUND R. THEWS. *Foundry* 56, 532-5(1928).—The effects have been studied of addns. of Zn, Pb, Ni, Co, Mn, P, Al, Fe and Si to bronze on such properties as shrinkage, expansion and segregation. **DOWNES SCHAAP**

Contraction in alloy castings. H. C. DEWS. *Proc. Inst. Brit. Foundrymen* 20, 395-426(1926-7).—Theoretical ideas are developed to account for the vol. and location of contraction cavities in alloy castings. The vol. of contraction cavities can be considerably reduced by (a) a low thermal capacity of the mold; (b) a high thermal capacity of the metal; (c) a low coeff. of expansion in the liquid and solid metal; (d) an algebraically low contraction on freezing; and (e) a low casting temp. Because of the diversity of shape of castings each design must be given individual attention so that the principle of directional cooling and feeding may be applied. In alloys which freeze through a range of temp. the molding practice should be manipulated so that the temp. gradient slopes evenly from the remotest points of the mold to the feeding point, in order to obtain sound castings. **DOWNES SCHAAP**

X-ray analysis and the crystalline structure of metal alloys. G. NATTA. Reale Politecnico di Milano. *Ann. chim. applicata* 18, 135-88(1928).—A crit. review and discussion of the literature of alloys and the methods of examn. (many references to which are included) shows the importance of Cd-Mg alloys, particularly from a theoretical point of view. Therefore a systematic x-ray examn. by the powder and by the Laue methods was made of Cd-Mg alloys of various compns. and under different conditions. In alloys rapidly solidified and immediately tempered, which represent modifications stable at high temps., the powder method shows 2 types of crystals, solid solns. of Mg in Cd and of Cd in the Mg lattice. Solid soln. crystals of Mg in Cd predominate in alloys contg. 100-50% Cd, whereas crystals of Cd in Mg predominate in the remaining range, the proportions being approx. equal in 50% alloys. In the solidification of 50% alloys, solid solns. of Cd in Mg contg. more Mg than the integral alloy first sep., followed by sepn. from the fusion mixt. rich in Cd of solid solns. of Mg in Cd. The segregation of the initial solid soln. of const. compn. explains the arrest observed in the cooling curve obtained by thermal analysis. The powder method excludes the existence of the compd. Mg-Cd stable at high temps. and with a cryst. structure different from its constituents. The cond. curve at high temp. can be interpreted on the supposition that the 2 branches of the curve correspond to the 2 solid solns., viz., Cd in Mg and Mg in Cd. The variations of the lattice consts. do not follow the Vegard law, the Cd cell increasing from 2.98 to 3.01 A. U. and the axial ratio decreasing from 1.89 to 1.875 for 0 to 40% Mg. The intensity of the Cd lines is changed by large proportions of Mg, indicating the regular distribution of Mg atoms in the Cd lattice. Likewise in solid solns. of Cd in Mg the cell dimensions decrease greatly with small proportions of Cd, the cell diminishing from 3.22 to 3.155 A. U. from 0 to 15% Cd. The Laue method indicates that in alloys contg. 30-60% Cd the atoms are regularly distributed. Cooled normally, alloys contg. under 30% Cd segregate in large crystals in regular orientation and with $c/a = 1.628$. From 200° to 150° these crystals are transformed into minute aggregates of new crystals which retain the form of the earlier crystals, and furnish a striking example of paramorphosis. With 60% Mg the elementary cell has dimensions which are multiples of those of Mg, probably $a = 18.9$ A. U. and $c/a = 0.1813$ (216 atoms). Solid solns. from alloys contg. initially less than 70% Mg are not ideal solns., the Cd atoms being arranged regularly in the Mg lattice. Alloys heated for a long time show by the powder method the lines of solid solns. in Cd, the lines of solid solns. in Mg disappearing except with high proportions of Mg. The abnormal phys. properties of heated 50% alloys are explained by the presence of solid solns. regularly distributed, the effect of atoms fixed stationary in the lattice of the solvent being the same as that of a compd. The relation between these results and those obtained by thermal analysis are discussed. **C. C. DAVIS**

Copper and brass. O. BAUER, FRIHR. V. GÖLER AND G. SACHS. *Z. Metallkunde* 20, 202-8(1928).—The metal and alloys examd. are E-Cu (99.93% Cu), Ms 98 (98.12% Cu - 1.63% Zn), Ms 90 (90% Cu - 10% Zn), Ms 85 (85% Cu - 15% Zn), Ms 72 (72% Cu - 28% Zn), Ms 63 (64% Cu - 36% Zn), Ms 60 (60% Cu - 40% Zn). The effect of the angle at which the sample is cut with respect to the rolling direction is detd. with respect to tensile strength. With E-Cu and Ms 98 there is no effect, but as % Zn increases, the tensile strength increases as the angle increases up to 90°. With Ms 85, tensile strength is about 68 kg./sq. mm. at an angle of 0° to the rolling direction and about 82.5 at 90°. X-ray photographs show practically no difference between Cu and brass in the form of rolled plate, but on annealing at 500° for $1/2$ hr., a progressive difference is obtained between Cu and 60-40 brass. Notch-test strength rises as annealing temp. is increased up to about 600°, after which there is only a slight decrease

in E-Cu and Ms 60, but a very large decrease in Ms 72, 85, 90. Tensile strength and elongation attain max. values with about 70% Cu on specimens taken perpendicular to the direction of rolling. Max. hardness is attained with Ms 60 by quenching from a temp. just at the point where α -crystals are converted into β -crystals (about 750°).

H. STOERTZ

Structure of aluminum-rich silver-aluminum alloys. M. HANSEN. *Z. Metallkunde* 20, 217-22(1928).—The alloys are prepd. from refined Ag and Al contg. 0.10% Si, 0.16% Fe. The equil. diagram is detd. from 0 to 60% Ag, and the soly. of Ag in Al is detd. microscopically from 200° to the eutectic temp. of 558°. The soly. is given as follows: at 200°—0.75%, at 250°—1.75%, 300°—3.25%, 350°—6.5%, 400°—12.0%, 450°—21.0%, 500°—33.0%, 558°—48.0%. The satn. limit at room temp. is about 0.45% Ag. Microscopic examn. indicates the existence of the compd. $AlAg_2$, which separates in the form of very small crystals when the alloy has been annealed at 200° to 300°. Quenched from higher temps., $AlAg_2$ separates in the form of variously oriented needles.

H. STOERTZ

Study of the structure of electrolytic copper by means of x-rays. JEAN J. TRILLAT. *Rev. métal.* 25, 286-8(1928).—Detn. of the size of the elementary cell of the crystal lattice, by means of the rotating-crystal method, in electrolytic Cu deposited from $CuSO_4$ soln. both contg. gelatin and without it by Marie's technic (*C. R.* 21, 3806) showed that in both cases electrolytic Cu belongs to the face-centered cubical system, and that the size of the cell is nearly the same in both cases (3.68 Å. U. without gelatin, 3.70 Å. U. with gelatin), and near that of ordinary Cu (3.60 Å. U. according to Bragg) Spectrograms obtained by the Debye-Scherrer method gave perfectly clear, fine and regular rings with Cu deposited in presence of gelatin, while Cu deposited without gelatin gave rings with a granular structure, which were really composed of a large no. of Laue spots practically side by side. In neither case was there any indication of a fiber structure or of orientation in a direction perpendicular to that of the x-rays, i. e., parallel to the plane of the cathode.

A. PAPINEAU-COUTURE

Significance of the casting structure on the properties of copper. O. BAUER AND G. SACHS. *Metall u. Erz.* 24, 154-64(1927); *J. Inst. Metals* 38, 464.—The paper contains a large no. of photographs of failures in Cu castings before and after working, of characteristic structures of overpoled and underpoled Cu and of the effect of Cu_2O and of reducing gases on the structure of the cast metal, together with an account of the value of x-rays and of the detn. of the sp. gr. in ascertaining the soundness of Cu castings. A table is also given showing the variation in the tensile properties of rolled Cu in different directions and after various mechanical treatments.

H. G.

Significance of the casting structure on the properties of copper. P. SIEBE. *Metall u. Erz.* 24, 288-9(1927); *J. Inst. Metals* 38, 464.—The long, fibrous, coarsely cryst. structure of some Cu castings is due to the presence of impurities, as little as 0.03% of Pb or 0.003% of Bi causing this structure if no Cu_2O is present, i. e., if the metal is overpoled. In "tough-pitch" Cu, which contains 0.05-0.08% of O, this quantity of impurities exists as oxide, which is not nearly so deleterious to the properties of the metal as is metallic Pb or Bi.

H. G.

Uses of nickel deposits in engineering. C. H. FARIS. *Trans. Inst. Eng. and Shipbuilders* 71, 209-42, 242-4(1927); *Science Abstracts* 31B, 185.—The requirements of heavy electrodeposited Ni are perfect adhesion, resistance to wear and immunity from corrosion, and the advantages claimed are the absence of the necessity of heat treatment, possibility of local application of treatment and wide range of metals possible of treatment. The results of tests are given which illustrate the perfect adhesion obtained, the resistance to wear of the deposited metal and its immunity from corrosion. Examples are given of the application of heavy Ni deposits to a variety of engineering parts.

H. G.

Stresses in non-ferrous castings. CECIL H. DESCH. *Proc. Inst. Brit. Foundrymen* 20, 106-24(1926-7).—Non-ferrous metals are liable to internal stresses due to the condition of solidification when cast into shapes which allow of the cooling of different parts at unequal rates. The stresses in some metals and alloys are accentuated by the cryst. nature of the material. Metals which crystallize in the cubic system contract the same in all directions, while others such as Zn, Bi, Sb and Cd, which crystallize in less simple form, contract more in one direction than another. Stresses are easily set up in an alloy composed of two constituents of very different phys. properties. Local heating subsequent to casting, such as burning in at defective places in castings, is likely to set up stresses. It seems very probable that rupture of alloys by chem. means does not occur unless a state of stress exists in the region to which the reagent penetrates.

DOWNES SCHAAF

Scientific views on the oxygen-cutting process. S. I. LAVROV. *Zentr. Hütten- u. Walzwerke*, 31, 169-72; *Chem. Zentr.* 1927, 1, 2773.—With gas contg. 78% O, the temp. of the section cut is the same as the kindling point of Fe, and therefore this O content should represent the theoretical limit of applicability of the O-cutting process. If the O is superheated or the metal prewarmed, it is possible to cut with 75% O. The use of pure O greatly diminishes the consumption of gas and the loss of time. A decrease in the O content leads to an increase of space over which the cutting takes place. During the cutting, there is carbonization on the surface, the C originating from the metal. With less than 0.35% C, this phenomenon is not evident. C. C. DAVIS

Instruments for testing the stamping qualities and tensile strength of sheet metals. R. GUILLERY. *Rev. métal.* 25, 148-50 (1928).—G.'s instrument for testing the stamping qualities of sheet metals has been perfected by means of an attachment which enables it to be used for detg. tensile strength. A. PAPINEAU-COUTURE

The influence of cold-working on specific heat. W. GEISS AND J. A. M. VAN LIEMPT. *Z. anorg. allgem. Chem.* 171, 317-22 (1928).—The equation $C_c - C_r = C_0 (R_c/R_r)\beta/\alpha$ is derived for the difference between the sp. heats of cold-worked and recrystd. metal. C_c , C_r and C_0 represent, resp., the sp. heat of the cold-worked metal, of the recrystd. metal at a temp. of t° and of the recrystd. metal at 0° . R_c and R_r are the sp. resistances and α and β are the coeffs. in the equations $R_c = R_r(1 + \alpha t)$ and $C_r = C_0(1 + \beta t)$. For W and Ni the calcd. difference is less than 0.5% and the measured difference is also less than this amt., in agreement with the theory. The sp. heats of pure W and Ni were detd. to be $0.0323 \pm 0.5\%$ and $0.1035 \pm 0.5\%$, resp. EDGAR R. SMITH

Study and commercial control of annealing and cold-hardening by means of the hardness test using a ball of small diameter under a small load. P. NICOLAU. *Rev. métal.* 25, 155-68 (1928).—The hardness test using a small-diameter ball under a small load constitutes an extremely rapid, simple and accurate method for studying and controlling cold-hardening and annealing after cold-hardening, either on test pieces or on small-sized finished articles, and can be applied as easily in the shop as in the lab. This method can be advantageously substituted for micrographic examn. in the field of application where its sensitiveness is greatest, namely, in the zone of low cold-hardening on the one hand, and, after annealing in the germination zone and at the beginning of the zone of complete annealing, on the other. For Cu and α brass, N. recommends a 1.58-mm. ball and 10-kg. load, which permits carrying out the tests on articles not less than 0.3 mm thick. The diameters of the marks should be detd. to less than 0.001 mm with a microscope (preferably under vertical illumination) having a magnification of 100 and provided with a micrometric ocular. The results of a systematic investigation of the influence of the degree of initial cold-hardening on the trend of the variation in hardness of Cu as a function of annealing temp. are given graphically, confirming and supplementing various results obtained by Charpy and by Grard, both for Cu and for brass. As a result of the extreme sensitiveness and accuracy of the method as described, N. discovered an anomaly in the annealing of Cu and α -brasses, which seems to be general and which is revealed by a max. in the hardness-annealing temp. curve. This anomaly is more pronounced with Cu and its sharpness increases the greater the initial cold-hardening. A. P.-C.

Slip interference theory of hardening. M. G. CORSON. *Mining & Met.* 9, 304-6 (1928).—Jeffries' theory is discussed and many instances of its applicability are given. The author divides alloys into six groups each one characterized by a certain velocity of pptn. of the hardening component and a certain velocity of growth of the grains pptd. A brief discussion of hardening and annealing of the alloys in the several groups is given. It is suggested that season cracking, loss of ductility when heated for a long time at 450° and other phenomena characteristic of the alpha alloys of Cu may be due to a pptn. of a secondary component. WILLIAM F. EHRET

Brinell hardness, static bending and shearing. R. GUILLERY. *Rev. métal.* 25, 151-4 (1928).—G.'s hardness tester has been adapted for carrying out bending and shearing tests also. The method of carrying out these 2 tests is described. A. PAPINEAU-COUTURE

A finely divided ore such as Cu ore is agitated with water and a small proportion of a mixt. contg. pressure-still tar 80, residuum from hydrolysis of sulfated olefins 19 and a water-sol. Na sulfonate of petroleum hydrocarbons 1%, and aerated to form a froth. U. S. 1,678,312 specifies a similar flotation mixt.

Flotation apparatus for treating ore pulps. EDWARD H. SHACKELFORD, JR. (to Hebbard Mfg. Co.) U. S. 1,678,087, July 24.

Ore concentration. CORNELIUS H. KELLER (to Minerals Sepn. North America Corp.). Can. 282,358, Aug. 7, 1928. Complex Ag-Pb-Zn ore is ground with Na₂S and the pulp is agitated with H₂O with addition of soda ash, K₂Fe(CN)₆, Na xanthate, Barrett No. 634 oil and cresylic acid, to produce a Pb froth rougher concentrate. To the remaining pulp are added CuSO₄, Na xanthate, Barrett No. 634 oil, and steam-distd. pine oil and the pulp is agitated to produce a Zn froth rougher concentrate. The Pb concentrate was reagitated with additional cresylic acid to form a finished Pb concentrate and a Pb middling. The Zn concentrate was reagitated with additional reagents to form a finished Zn concentrate and a Zn middling.

Ore concentration. TUDOR R. SIMPSON (to Minerals Sepn. North America Corp.). Can. 282,357, Aug. 7, 1928. Ores carrying a substantial amt. of normally floatable insol. silicate gang are concd. by agitating a pulp of the ore with a mineral frothing agent and a xanthate to yield a mineral-bearing froth carrying a relatively large proportion of a mineral of the ore accompanied by a large proportion of said silicate, sepg. the froth, agitating a pulp of the froth concentrate with a further addition of starch so as to yield a froth concentrate relatively rich in said mineral and relatively free from said silicate, and sepg. the froth concentrate. Cf. C. A. 21, 2454.

Concentration of ores. MINERALS SEPARATION LIMITED. Fr. 633,679, Sept. 3, 1926. Substances contg. a complex radical, e. g., ferricyanides, are added to the frothing agent, which may be an org. compd. contg. S such as a xanthate.

Concentrating table for treating ores. ALBERT H. STEBBINS. U. S. 1,678,364, July 24.

Concentrating mixed sulfide ores. HAROLD S. MARTIN. U. S. 1,678,259, July 24. In effecting selective froth flotation of Cu sulfides from ores contg. Fe sulfides, the ore pulp is rendered alk. and a substance such as NH₄HSO₄ is added which is capable of "liberating the SO₂ radical" and H ions during the flotation.

Treatment of slags. ÉMILE BOHON. Fr. 633,448, Aug. 27, 1926. Slags from old hand forges and from the refining of pig iron are made into briquets with a flux such as alkali carbonates and CaF₂ intimately mixed, powdered charcoal and pitch. The briquets are treated in the usual way.

Reducing iron ores. I. G. FARRINGTON. A.-G. Brit. 280,970, June 19, 1926. In a modification of the process described in Brit. 278,167 (C. A. 22, 2544) the gas used for reduction is prepd. from natural gas, coke-oven gas or gases resulting from

cracking processes, or similar gases, and O or air rich in O. Gases resulting from the reduction process may be used for other purposes, such as in hydrogenations.

Zinc from ore or oxide. H. R. COLLEY. Brit. 281,129, Feb. 2, 1927. Preheated ore or oxide is further heated to a reducing temp. by passing it as a thin stream through a heated zone and, at points of suitable reducing temp., is supplied with a hydrocarbon reducing agent which is introduced through cooled pipes or conveyers so that it is decomposed only after contact with the material to be reduced. An app. is described.

Reducing zinciferous materials. JAMES A. SINGMASTER, FRANK G. BREYER and EARL H. BUNCE (to New Jersey Zinc Co.). U. S. 1,678,607, July 24. See Brit. 269,324 (C. A. 22, 1319).

Extracting minerals. MAX C. HELSON. Fr. 632,596, Apr. 11, 1927. Minerals are sepd. from gang, by a flotation process in which oil or gasoline is added, the flotation being hastened by passing through it water satd. with CO_2 under pressure, the flotation vessel being open to the atm.

Combined mill, converter, drier and classifier for treating ores. WALTER DUSENBERG and JOHN H. MACARTNEY. U. S. 1,678,002, July 24.

Rotary furnace for two-stage ore reductions, calcining and sintering operations, etc. F. L. DUFFIELD. Brit. 281,338, Nov. 29, 1926. Two rotary furnaces are used alternately for each stage of the treatment in reducing Fe ore or other processes. Various structural features are described.

Furnace for heat-treatment of metal sheets and plates. JOHN W. PERRY. U. S. 1,678,300, July 24.

Apparatus for recovering precious metals by amalgamation. JAMES F. HOPKINS. U. S. 1,678,142, July 24.

Ingot molds, ladles and converters. G. DURVILLE. Brit. 280,963, Nov. 19, 1926. Structural features.

Centrifugal apparatus for casting metals. A. PORTEVIN (to Soc. d'expansion technique). Brit. 280,929, Nov. 17, 1926.

Apparatus for casting pipe, etc., centrifugally. J. H. UHRIG (to International De Lavaud Mfg. Corp., Ltd.). Brit. 281,251, Nov. 23, 1926.

Tumbling apparatus for cleaning foundry castings. FREDERICK W. NEVILLE (to J. W. Jackman & Co., Ltd.). U. S. 1,678,072, July 24.

Ferrous castings with chromium-alloy surfaces. WALTER M. MITCHELL (to Electro Metallurgical Co.). U. S. 1,677,979, July 24. The surface of the mold used for casting is coated with a mixt. of Cr and a binder such as Na silicate and the base metal is poured under a ferriostatic head of 20-30 in. to prevent running of the alloy coating on the casting. An app. is described.

Malleable cast iron. SOC. ANON. FORGES ACIÉRIES DE FIRMINY. Fr. 632,399, July 26, 1926. Ni or Cu from 0.5 to 10%, is added to cast iron or materials from which it is obtained to reduce the thermal operations necessary to bring it to the malleable state.

Pickling and other treatments of metal sheets. W. E. WATKINS. Brit. 281,575, June 16, 1926. An app. is described. Brit. 281,577 specifies an app. for coating metal plates with oil or other substance before annealing and for giving them a fine-grained surface by action of rollers.

Treating metal sheets for pickling, washing, etc. W. E. WATKINS. Brit. 281,349, June 16, 1926. Mech. features.

Apparatus for pickling or cleaning metal articles. UNITED WIRE WORKS (Birmingham), LTD., AND H. LOWNDES. Brit. 281,125, Jan. 29, 1927. The articles are carried by conveyers through vats which may contain acid or other pickling or cleaning solns. A soln. of H K tartrate may be used.

Elongating metals. W. C. CORYELL. Brit. 281,364, Aug. 26, 1926. By simultaneous application of tension and rolling pressure, a high degree of elongation may be effected with re-annealing.

Refining and separating metals. SOC. MINIÈRE MÉTALLURGIQUE DE PENARROYA. Fr. 632,921, Apr. 16, 1927. An oxy salt of Sn is sepd. from oxy salts of As and Sb by treating the mixt. with a cold NaOH soln. of such a concn. that it dissolves only the oxy salt of Sn.

Refining and separating metals. SOC. MINIÈRE MÉTALLURGIQUE DE PENARROYA. Fr. 632,920, Apr. 16, 1927. Small quantities of Sb and Pb contained in alk. liquors from refining processes in which NaOH is used are sepd. by treating the soln. with reducing agents such as Sn or SnCl_2 .

Metallurgical carbon. GEORGES DE KORFF and GASPARD JAKOVA-MERTURI. Fr. 632,023, Apr. 11, 1927. Carbon for use in steel and iron making is prepd. by car-

bonizing charcoal without distn or using a charcoal incompletely decomposed by the weather, such as lignite and mixing it with or allowing it to absorb a finely ground nitrate, particularly NaNO_3 or an alkali borate or both.

Aluminum. RUDOLF JACOBSSON. Fr. 632,205, Apr. 5, 1927. Minerals contg. Al are attacked by H_2SO_4 or acid sulfates under pressure at a temp. of 185° or more, the addition of the H_2SO_4 being gradual and the mineral being made into a sludge with wash water from a previous operation. The product is filtered while still hot.

Steel. H. MEYER. Brit. 281,621, Dec. 6, 1926. Ingot steel such as may be used for boilers, reservoirs, tubes or construction work is subjected to a cold straining by rolling or drawing and is then annealed by heating to $700-950^\circ$ and air-cooling.

Steel. GRANULAR IRON COMPANY. Fr. 632,888, Apr. 15, 1927. In making steel from minerals contg. such substances as TiO_2 the mineral is reduced so as to leave the TiO_2 as oxide by allowing the mineral to remain solid. The TiO_2 is removed in the gang formed.

Special steels. THOMPSON PRODUCTS INCORPORATED. Fr. 633,213, Apr. 16, 1927. Alloys known as special steels used for such purposes as engine valves are made from Cr, Ni, Si, C and Fe within the following limits, Cr 5 to 20%, Ni 0 to 14%, Si 1.5 to 5%, C 0.1 to 0.75% and the rest of Fe, the amount of Cr and Ni together being between 13 and 21.5%. The heat treatment consists in submitting the alloy normally in the austenite form to a high temp. (870°) kept substantially constant for over 4 hrs. then cooling it slowly at a speed not exceeding 40° per hr. for over 3 hrs.

Permanent-magnet steel. PORTER H. BRACE (to Westinghouse Elec. & Mfg. Co.). U. S. 1,678,001, July 24. A magnet steel comprises Co 1-10 and Cr or other metal of the Cr group 1-10%, the remainder being mainly Fe and minor impurities.

Aluminum alloys. SOC. TH. GOLDSCHMIDT A-G. Fr. 632,942, Apr. 16, 1927. Al alloys used as elec. conductors are submitted after annealing, tempering and mechanical cold treatment to a rest period of some days at ordinary temp. followed by reheating to 200° for some days.

Alloys of copper and aluminum. METALLBANK UND METALLURGISCHE GES. A. G. Fr. 632,713, Jan. 13, 1927. A relatively large proportion of Mg is added to Cu and Al alloys (Al bronzes) to counteract the effect of Ni and Fe therein. An example of an alloy is Cu 83%, Al 9%, Mg 3%, Ni 2%, Fe 3%. Fr. 632,714 describes similar alloys to which Sn is also added, for instance Cu 84%, Fe 1.5%, Mg 5%, Al 9%, Sn 0.5%. Cf. C. A. 22, 1321.

Lead alloy. SYDNEY BECKINSALE and HERBERT WATERHOUSE. Fr. 632,220, Apr. 6, 1927. See Brit. 272,320 (C. A. 22, 1755).

Cast iron alloys. INTERNATIONAL NICKEL CO. Brit. 281,051, Oct. 4, 1926. Cast Fe alloys contain about 2-4% C contain also Ni 5-35 and Cr 2-15% (the Ni always being in excess of the Cr). Small proportions of Cu, Al, Si and Mn also may be present.

Gray iron alloys. PAUL D. MERICA, JAMES S. VANICK and THOMAS H. WICKENDEN (to the International Nickel Co.). Can. 281,987, July 24, 1928. A gray-Fe casting contains C 2-4%, Si 0.5-1.5%, Ni 1-5%, Cr up to 2%, S, P and Mn within the usual ranges found in cast iron, the Ni content being greater than the Cr content.

Silver alloys. SOC. FRANÇAISE MONNAYAGE. Fr. 632,368, July 22, 1926. Alloys of Ag contg. Ag, Ni, Cu and Zn or Cd suitable for money or silver articles are described. One example gives Ag 35, Ni 12, Cu 38, Zn 15%. Two intermediate alloys may be formed, one contg. Cu and Ni, the other Ag and Zn, the second alloy being formed by heating the two metals slowly from the point of fusion of Zn to that of the alloy sought.

Steel alloy. WALTER DORTMUND. Can. 282,241, Aug. 7, 1928. A structural steel contains 0.5-1.5% Si and 0.1-0.5% Cu.

Alloy for pistons of glass surgical syringes. F. KRUPP AKT.-GES. Brit. 281,625, Dec. 6, 1926. In order to avoid breaking the glass by unequal expansion during sterilization, pistons are used which are formed of Ni steel preferably contg. 36% Ni, which has a low coeff. of thermal expansion.

Prevention of rust. PARKER RUST-PROOF COMPANY. Fr. 632,891, Apr. 15, 1927. See Can. 281,317 (C. A. 22, 2917).

Protecting the surface of metals. JULES DUBOIS. Fr. 632,510, Apr. 9, 1927. To protect the surface of metals, especially under heat treatment, they are covered with a layer consisting of a powdered mixt. of sand, feldspar, borax and Na which may be applied by mixing with water.

Coating iron or steel with phosphates. PARKER RUST-PROOF CO. Fr. 632,342, Apr. 7, 1927. Iron or steel is coated with phosphates of Fe and Mn, the content of Mn in the coating being at least half the content of Fe and the relation of metal to P

being 6 atoms of the former to 5 of the latter. The iron objects to be coated are placed in a dilute soln. of phosphoric acid and the phosphates. Cf. *C. A.* 22, 2917.

Coating iron with zinc or tin. T. LIBAN. Brit. 281,357, July 20, 1926. Before dipping iron articles into molten Zn or Sn (which may contain a small proportion of Al) the articles are dipped into a molten bath or soln. of a mixt. of F compds. and ZnCl_2 or Zn NH_4 chloride, e. g., a mixt. formed of KF 0.5-6, NH_4Cl 10-20 and ZnCl_2 74-89.5%. For Sn coating, tallow, resin or palm oil may be added. The metal-coating bath may carry the preliminary treating bath on its surface.

Metal plating. EZECHIEL WEINTRAUB and SOC. ALSACIENNE DE CONSTRUCTIONS MÉCANIQUES. Fr. 632,407, July 27, 1926. To increase the adherence of a coating of Ni, Co, or Cr on a metallic surface, the object with one layer of one of these metals is heated in a vacuum or under reduced pressure to a temp. sufficient to cause the coating metal to attack the metal underneath.

Treating the surfaces of articles made from chromium-iron alloys. LOUIS SCHULTE (to Allegheny Steel Co.). U. S. 1,678,359, July 24. The surfaces of articles such as those contg. Cr 8-60% are cleaned after heating, by frictional treatment with pebbles or hard alloy or other suitable scouring material, in the presence of HNO_3 soln. which serves to produce a finish resembling Ag.

Hardening and toughening screw-cutting taps. R. F. KNIGHT and F. LYNCH. Brit. 281,384, Sept. 1, 1926. A hole is drilled longitudinally through the tap and is filled with clay or like material and the tap is then hardened by heating. Afterward, the clay is removed and the tap is further toughened by heating it with an elec. resistance wire or by hot air or molten metal passed through the hole.

Preventing corrosion in boilers, oil stills, pipe lines, etc. J. CALDER. Brit. 280,991, July 28, 1926. A finely divided compn. formed of Fe, graphite and Zn, with or without Al, is fed into the liquid. An app. is described.

Recovering oil from tin plates after tinning. THOMAS O'BRIEN and RUFUS E. ZIMMERMAN (to American Sheet and Tin Plate Co.). U. S. 1,678,297, July 24. Both sides of the plates are scrubbed with a non-inflammable liquid such as an aq. soap or soda soln. from which the oil may be readily recovered and the plates are further squeezed and rubbed to remove adhering liquid and are then passed through a body of bran or other suitable cereal material to remove remaining oil and moisture. An app. is described.

Annealing box for metal articles. WILLIAM E. TROUTMAN (to Duquesne Steel Foundry Co.). U. S. 1,678,452, July 24. Structural features.

Apparatus for annealing metal sheets and cooling them in a non-oxidizing atmosphere. W. E. WATKINS. Brit. 281,578-9, June 16, 1926.

Apparatus for annealing metals. SIEMENS ELEKTROWARNE-GES. Fr. 633,657, May 2, 1927.

10—ORGANIC CHEMISTRY

CHAS. A. ROULLER and CLARENCE J. WEST

The manufacture of vanillin. ALFRED WAGNER. *Chem.-Ztg.* 52, 525-6, 542-3 (1928).—Descriptive. A. L. HENNE

X-ray examination of a cellobiose anhydride. MAX BERGMANN, R. O. HERZOG AND W. JANCKE. *Naturwissenschaften* 16, 464(1928).—X-ray diagrams of the cellobiose anhydride described by B. and Knehe (*C. A.* 20, 381) are identical with those of hydrated cellulose. The diagram of the hexaacetate was identical with that of cellulose triacetate. B. J. C. VAN DER HORVEN

Nierenstein reaction. M. NIERENSTEIN. *Nature* 121, 940-1(1928).—Reply to Bradley and Robinson (*C. A.* 22, 3150). DAVID DAVIDSON

Transformation of hexadecene under the influence of active hydrogen. H. I. WATERMAN AND J. N. J. PERGUIN. *Ann. scuola ing. Padova* 3, 383-5(1927).—When hexadecene was exposed to active H several hrs., it assumed a slightly yellow color, although remaining liquid. The Br no. was reduced $\frac{1}{3}$, but the refractivity was markedly increased, suggesting polymerization. Oleic acid under similar treatment has already been proved to produce a small amount of stearic acid. The O content of the H used precluded an oxidation reaction. Compn. before, C 85.8, H 14.4; after, C 85.4, H 14.6%. A. W. CONTIERI

The activity of halogen in certain compounds of the propane series. V. V. TRONOV AND A. T. GERSHEVICH. *J. Russ. Phys.-Chem. Soc.* 59, 727-39(1927).—The introduction of an electronegative atom into a hydrocarbon causes the electronic shells of

the neighboring C atoms to contract and expand alternately, resulting in induced polarity. Another halogen in the β -position will have a cumulative, in the α an opposite effect. Assuming the polarity of a double linkage according to Lowry, C:C would induce ionization in the β - and C:O in the α -position. The activities of 18 halides of C_6H_5 and propene towards C_6H_5N and MeONa were compared, the first reaction only being of the ionic type. Equimol. quantities of the compd. and C_6H_5N or 1 N MeONa in MeOH were sealed and left at room temp. C_6H_5NHX was dissolved in H_2O , washed with $CHCl_3$, warmed to 80-90° to drive $CHCl_3$ off and titrated according to Volhard. The excess of MeONa was titrated with HCl. The reactivity of the halides towards MeONa varies much less than towards C_6H_5N . A second α -halogen decreases the activity towards C_6H_5N , while one in the β -position increases it. With MeONa activity increases on the introduction of another halogen, especially in the α -position. The primary halides react with C_6H_5N 6-40 times, with MeONa 2-8 times faster than the secondary. An α -double linkage increases the activity of PrCl towards C_6H_5N 162, of PrBr 300 and of PrI 385 times. The increase in activity towards MeONa is, resp., 44, 72 and 78. $ClCH_2CHCH_2Cl$ is 60 times more active towards C_6H_5N and twice towards MeONa than $(ClCH_2)_2CH_2$. A OH behaves like an additional halogen.

BASIL C. SOYENKOFF

β, β' -Dicyanodiethyl sulfide. V. V. NEKRASOV. *J. Russ. Phys.-Chem. Soc.* **59**, 921-4 (1927).—To 70 g. $CH_2(OH)CH_2CN$ (obtained from $CH_2(OH)CH_2Cl$ and KCN) in 80 cc. $CHCl_3$ was slowly added 130 g. $SOCl_2$ at 0-5°. After standing overnight 55-60 g. of $ClCH_2CH_2CN$ was distd. *in vacuo* and refracted at atm. pressure (b. 170-2°, yield 40-50 g.). To 24 g. of the Cl compd. and 11 g. anhyd. Na-S in abs. Et₂O is added an equal vol. of MeOH. The reaction is controlled by cooling, the mixt. being finally refluxed for 4 hrs., filtered and evapd. The resultant oil is dissolved in 120 cc. hot H_2O ; $S(CH_2CH_2CN)_2$ seps., on cooling and concn., in needles, m. 24.5°, yield, 14 g. The dibasic acid $C_6H_{10}O_4S$ results on boiling the nitrile with concd. HCl for 2 hrs.

BASIL C. SOYENKOFF

Preparation of mercury dimethyl. KARL FUCHS. *Univ. Vienna. J. prakt. Chem.* **119**, 209-10 (1928).—Shaking 55 g. acid-free Me_2SO_4 and 10 g. $AcOMe$ with 2 kg. 0.5% freshly prepd. Na-Hg, until the reaction mixt., which reaches 60-70°, is cool, then adding 200 cc. H_2O and distg. with steam, gives 32 g. pure $HgMe_2$, b₇₆₀ 91.5-2.5° (60-5% yields). Et_2SO_4 also gives $HgEt_2$ but the yields are no better than with $EtBr$.

C. J. WEST

The chemical nature of hydroxycitronellal. ALMONS M. BURGER. *Richtstoff-industrie* **1927**, 23 5. *Chem. Zentr.* **1927**, I, 1756 7.—The prepn. of hydroxycitral and hydroxycitronellal is described in detail. According to the general reaction of ethylene bonds with salts of SO_3 , the residue contg. S (which in the decompn. furnishes the OH group) adds to the C atom farthest from the group already contg. O. There are 2 possible formulas for hydroxycitronellal: $Me(HOCH_2)CHCH_2CH_2CHMeCH_2CHO$ and $Me_2C(OH)CH_2CH_2CHMeCH_2CHO$. It b₁₅ 116-7°, d₁₅ 0.923-0.925, n_D²⁰ 1.45, is sol. in 6.5 vols. of 30% EtOH, and is miscible in all proportions with 50% EtOH.

C. C. DAVIS

Quantitative study of the oxidation of methyl oleate and elaidate by hydrogen peroxide in presence of acetic acid. THOMAS P. HEDITCH AND COLIN H. LEA. *Univ. of Liverpool. J. Chem. Soc.* **1928**, 1576 83.—In a study of the oxidation of Me oleate and elaidate by H_2O_2 in AcOH, there is no indication of the formation of oxido compds. (cf. Bocseken, *C. A.* **22**, 2877), whether carried out at the ordinary temp. or at 95°, but there is definite evidence of the concurrent formation of 3 types of oxidation product varying in quantity according to the temp. of oxidation. Simple dihydroxystearic esters are produced in appreciable quantities, especially at the lower temps. They sepd. from the oxidation mixt. as a cryst. deposit and were isolated by crystn. from Me_2CO at 0°; the yields obtained represented min. values. Acetylated dihydroxystearic esters are produced to the extent of only about 50% of the total product at room temp., but in much larger quantity as the temp. is increased. The % of AcOH combined in the original oxidized ester was detd., and hence was calcd. the total quantity of mono-acetylated esters present. An oily product is also formed, like the di-HO ester, in greater quantity at lower temps. It has all the properties of an unsatd. fatty oil or ester which has been exposed to atm. oxidation and is largely made up of a compd. in which mol. O is held very loosely in direct combination with the unsatd. system. It instantly liberates I from acidified KI soln. and on heating to about 100° under reduced pressure froths violently and evolves small quantities of acrid vapors with an acid reaction. After hydrolysis of the original product, followed by removal of as much dihydroxystearic acid as possible, the oily substance shows no reaction to acid

KI and has an apparent sapon. equiv. of the order of 220–45°; ultimate analysis gave figures in agreement with the addn. of 2 atoms of O per ethylenic linkage, $C_{17}H_{30}(O_2)-CO_2H$. C. J. WEST

Properties of conjugated compounds. V. The hydrogenation of certain extended heterogeneous systems. JOHN T. EVANS AND ERNEST H. FARMER. Imperial College Science Tech., London. *J. Chem. Soc.* 1928, 1644–50; cf. *C. A.* 22, 1948.—Previous results with strongly acid or alk. reducing media showed that muconic acid, its esters and its α,α' -dihalogenated (substituted) derivs. are converted into Δ^8 -dihydro compds. To these methods is now added reduction in neutral soln. with Al-Hg. Et muconate in moist Et_2O and Al-Hg for 16 hrs. give pure Et Δ^8 -dihydromuconate. Hydrogenation of MeCH:CHCH:CHAc gave about 80% of a compd. derived from 2 mols. of the ketone, doubtless a cyclized form of the diketone MeCH:CHCH(CH₂Ac)CH(MeCH:CH)CH₂Ac, b_n 169–78°, it absorbs 4 atoms H when catalytically reduced, giving 5-acetyl-1-methyl-3,4-dipropenylcyclopentan-1-ol; with CrO_3 this gives $(CH_2CO_2H)_2$. Reduction of sorbic acid with Al-Hg or Na-Hg in AcOH gives a mixt of Δ^6 - and Δ^7 -dihydrosorbic acids. C. J. WEST

Alkali compounds of polyhydric alcohols and carbohydrates. LEOPOLD SCHMID, ALFRED WASCHKAU AND ERNST LUDWIG. Univ. Vienna. *Monatsh.* 49, 107–10 (1928).—Glycol, glycerol, glucose, fructose, glycogen and chitin readily dissolve in a soln. of Na in liquid NH_3 to yield a mono-Na compd. That there is no other change than a replacement of H by Na is shown by the fact that the inulin recovered by treatment of the Na compd. with H_2O , is unchanged in rotation. Near the b. p. of NH_3 , glycogen reacts with more than 1 Na atom, but the reaction is apparently complex and proceeds very slowly. C. J. WEST

New convenient preparation of 1,4-dihydroxybutane(tetramethylene glycol) and 1,4-dibromobutane. ADOLF MÜLLER. Univ. Vienna. *Monatsh.* 49, 27–30 (1928).—Reduction of $(CH_3CO_2Et)_2$ with Na and EtOH gives 54.4% of $(CH_2CH_2OH)_2$, b_{10} 120°. Passing HBr into the glycol at 80° gives 70% of $(CH_2CH_2Br)_2$. C. J. WEST

Nitration process in general and nitration of glycerol in particular. A. N. MASHKIN. Shostka Technicum. *Ukrainskii Khim. Zhurnal* 3, No. 1, sci. pt., 59–113 (1928).—The speed of nitration, the quality of nitroglycerin obtained and the quant. yield depend on the compn. of the nitrating mixt. Nathan and Rintoul (cf. *C. A.* 2, 1619) studied the action on glycerol of various nitrating mixts. and gave curves expressing the change in the products obtained as a function of varying proportions of HNO_3 and H_2SO_4 used; Pascal (cf. *C. A.* 20, 667) supplemented these curves by a diagram. These graphic representations, however, tell us nothing of the mol. structure of the nitrating mixts. and it is difficult to utilize them for practical purposes as well as for understanding the course of the nitration process. The reason is that the nitrating mixts. do not merely consist of a phys. mixt. of mols. of HNO_3 , of H_2SO_4 and of H_2O , but form various hydrates which react with each other as well as with glycerol and with nitroglycerin in a manner totally different from each other and peculiar to each particular hydrate. Aside from the monohydrates HNO_3 and H_2SO_4 , the following hydrates exist in the nitrating mixts.: mesonitric acid, H_3NO_4 ; orthonitric acid, $N(OH)_3$; and $H_2SO_4 \cdot H_2O$, $H_2SO_4 \cdot 2H_2O$, $H_2SO_4 \cdot 3H_2O$, $H_2SO_4 \cdot 4H_2O$ and $H_2SO_4 \cdot 5H_2O$. In all processes of nitration the formation of hydrates and their equil. in the nitrating mixt. have a very great importance. If instead of merely representing nitrating mixts. in % of HNO_3 and H_2SO_4 taken we translate them into mol. formulas of acid hydrates existing in the mixt. we shall find that the exptl. data and curves given by Nathan and Rintoul can very well be interpreted and understood and that it is easy to calc. in advance the best proportions of acids to use for nitration purposes. All the windings and bendings of the curves given by Nathan and Rintoul are satisfactorily explained by M. in detail on the basis of the properties of the various acid hydrates formed. HNO_3 effects nitration and soln. of nitroglycerin formed, strong sulfuric acids decomp. it, H_3NO_4 and the lower hydrates of HNO_3 cause oxidation. The min. of absorption of nitroglycerin takes place with mixts. of the compn. $2HNO_3 + 5(H_2SO_4 \cdot H_2O)$, and this should be the compn. of the nitrating mixt. at the end of the process. A simple calcn. shows that, in order to obtain the best results, the nitrating mixt. should be compounded of 43.4% pure HNO_3 and 56.6% pure H_2SO_4 (aq. HNO_3 can be used to obtain this compn., but in that case a certain proportion of oleum should be used instead of H_2SO_4) and that 520.8 parts of this mixt. should be made to react with 92 parts of glycerol; in that case 385.8 parts of used-up acid mixt. will be found at the end of the reaction and these will hold in soln. 9.7 parts of glycerol, whereas the amount of nitroglycerin obtained will be 217.3 parts, i. e., a yield of 236.2%. Exptl. data obtained by Soddy (*C. A.* 5, 1841; 6, 1226), Göpner (*C. A.* 6, 1228), Hof-

wimmer (*C. A.* 6, 1804; 7, 1100), Naum (in his book "Nitroglycerin und Nitroglycerinsprengstoffe") are also satisfactorily explained on the basis of M.'s theory of the role of hydrates in the nitration process. BERNARD NELSON

The C₄-saccharinic acids. IV. Further studies in the preparation of 2,3-dihydroxybutyric acid. GLADYS LEAVELL. *Abstracts of Theses, Univ. Chicago, Science Series* 4, 99-104(1925-6) (publ. May, 1928).—A process for the large-scale prepn. of the γ -lactone of 2,3-dihydroxybutyric acid (I), yielding about 54%, is described. The starting material was glycerol, the intermediate products were CH₂(OH)CH(OH)CH₂Cl (II) (710 g. from 1000 g. glycerol, 1350 cc. concd. HCl and 48 cc. AcOH at 120°) and CH₂(OH)CH(OH)CH₂CN (III) (from II and KCN in dil. EtOH). III was hydrolyzed to I by means of Ba(OH)₂. The m. p. of the phenylhydrazide of I is 109° instead of 100-1°, as reported by Glattfeld and Miller (*C. A.* 15, 532). Reduction of I with Na and abs. EtOH gave a liquid, b₁₈ 188°; probably it is 1,2,4-trihydroxybutane. The γ -lactone of 3-hydroxy-1,2-crotonic acid (IV) is a by-product of the hydrolysis of III. With PhNHNH₂, IV gave yellow needles, m. 183°; this substance is not the regular phenylhydrazide. G. SCHWOCH

The mechanism of the transformation of ricinoleic acid. P. S. PANYUTIN. *J. Russ. Phys.-Chem. Soc.* 60, 1-6(1928).—The crude oil was saponified, thrice salted out and Pb(OAc)₂ added. The Pb salt was extd. with Et₂O contg. 10% PhH and decompd. with H₂SO₄. The free acid was extd. with PhH, and the soln. allowed to stand for a week over CaCl₂; yield, 72-5%. The Me ester distd. at 150 mm. over NaBO₃ and pumice gave 90-2% of Me(CH₂)₈CHO and 60-87% Me(CH₂)₈CO₂Me; when the pressure was lowered to 8-10 mm. the ester distd. unchanged and no isomer could be found in the residue. Distn. at 80-100 mm. does not change α_D of the ester although decompn. begins at that pressure. At 320° and atm. pressure polymerization takes place; the unchanged ester distils over when the pressure is lowered. No isomers were detected after sudden cooling of the reaction mixt. No evidence was thus obtained for the shifting of the double bond preliminary to its rupture. The directing action of the OH group on the double bond is more probable. BASIL C. SOVENKOFF

Interaction between hydrazine and α -oxides and α -monochlorohydrins. A. K. PRISOV. Kharkov Inst. of Popular Education. *Ukrainskii Khim. Zhurnal* 3, No. 1, sci. pt., 125-31(1928).—Continuing the researches of Knorr (*Ber.* 35, 4474(1902)) and of Krasuskii (*C. A.* 2, 2226, 2548); *J. Russ. Phys.-Chem. Soc.* 39, 16(1907)) P. obtained 3 hydrazino alcs. and their derivs. To obtain hydrazino alc. contg. 2 mols of ethylene oxide per 1 mol. of hydrazine a mixt. of 2.5 or 3 mols. of ethylene oxide and 1 mol. of a 50% aq. N₂H₄·H₂O was, on strong cooling, sealed in a tube and left standing at room temp. The reaction was at first very violent. After 24 hrs. the tube was heated 1 hr. on a water bath and opened. Water and unchanged oxide having been driven off from the reaction mixt. by heating to 110°, the remaining thick oily liquid, b₂₅ 189°, represented [CH₂(OH)CH₂]₂NNH₂ (yield, 60%), non-crystallizing substance with an amine odor, decomps. on heating and on long keeping, reacts with aldehydes and ketones, a circumstance which proves its non-symmetric structure, reduces cold Ag₂O and Fehling soln. To obtain hydrazino alc. composed of 1 mol hydrazine and 1 mol. ethylene oxide, 50% aq. soln. of ethylene oxide (1 mol.) and N₂H₄·H₂O (4 mols.) were mixed with cooling and, on being sealed in a tube, were left standing at room temp. for 24 hrs. after which the tube was opened, the water and excess of N₂H₄ were distd. off and the residue was distd. under reduced pressure. The fraction b₂₅ 140-53° was redistd. and this time it b₂₅ 146-53°. The CH₂(OH)CH₂NNH₂ obtained possessed a strongly alk. reaction, had a bitter taste, and reduced cold Ag₂O and Fehling soln.; its alc. soln., on being satd. with HCl, gives white long needles of CH₂(OH)CH₂NNH₂·2HCl. The fraction b. 178-90°, which was equal in wt. to the above-described lower-boiling fraction, consisted of [CH₂(OH)CH₂]₂NNH₂. To obtain the hydrazino alc. contg. 1 mol hydrazine per 2 mols. trimethylene oxide a mixt. of 2 mols. of trimethylene oxide and 1 mol. N₂H₄·H₂O (the latter in 50% aq. soln.) was sealed in a tube and heated on a water bath 4-5 hrs. The tube was opened, the water and unchanged ingredients were driven off by heating at 110-5° and the residue was distd. at 44 mm [Me₂C(OH)CHMe]₂NNH₂ b. 185-90°. It is a thick liquid with an onion odor, bitter to the taste, non-volatile with water vapor, sol. in water, alc. and ether, crystg. on long keeping in white oblong crystals. It reacts with cold Ag₂O and Fehling soln. By satg. its alc. soln. with HCl is obtained [Me₂C(OH)CHMe]₂NNH₂·2HCl which crysts. in long hygroscopic needles sol. in water, poorly sol. in alc., insol. in ether, decomp. on heating and even on keeping; the HCl salt reduces cold Ag₂O and Fehling soln. To obtain the Bz deriv., [Me₂C(OH)CHMe]₂NNBz₂, a mixt. 4 g. of [Me₂C(OH)CHMe]₂NNH₂ in Et₂O with 12 g. K₂CO₃ and 12 g. BzCl was heated

on a water bath 4 hrs. The residue after evapn. of the ether was freed of admixts. and crystd. from alc. Small white needles insol. in water and ether, poorly sol. in alc. and ligroin. It reduces Fehling soln. after prolonged boiling. $[\text{Me}_2\text{C}(\text{OH})\text{CHMe}]_2\text{-NNH}_2$ was also obtained among the products of the reaction of an excess of N_2H_4 with $\text{Me}_2\text{C}(\text{OH})\text{CHMeCl}$ by operating in a sealed tube heated in an elec. furnace 5-6 hrs. at $120-30^\circ$; trimethylethylene oxide, $\text{Me}_2\text{C}(\text{CHMe})_2\text{O}$, is also found among the

products of reaction, whereas in the reaction between N_2H_4 and $\text{CH}_2\text{ClCH}_2\text{OH}$ ethylene oxide is obtained. Krasuskii's statement that the formation of α -oxamines from α -monochlorohydrins goes on through the intermediate formation of an α -oxide is confirmed by P.

BERNARD NELSON

Action of certain dibromotetracarboxylic esters on the sodium derivatives of ethyl malonate, ethyl ethanetetracarboxylate and analogous substances. JOHN J. LENNON AND WM. H. PERKIN, JR. Dyson Perrins Lab., Oxford. *J. Chem. Soc.* 1928, 1513-28.— $\text{Br}_2\text{C}(\text{CO}_2\text{Et})_2$ and $(\text{EtO}_2\text{C})_2\text{CNaCNa}(\text{CO}_2\text{Et})_2$ give about 60% of $[\text{C}(\text{CO}_2\text{Et})_2]_2$ (I);

$\text{CH}_2[\text{CBr}(\text{CO}_2\text{Et})_2]_2$ and $\text{CHNa}(\text{CO}_2\text{Et})_2$ give $\text{CH}_2\begin{matrix} \diagup \text{C}(\text{CO}_2\text{Et})_2 \\ \diagdown \text{C}(\text{CO}_2\text{Et})_2 \end{matrix}$ (II) and $[\text{CH}(\text{CO}_2\text{Et})_2]_2$

(III). With $[\text{CNa}(\text{CO}_2\text{Et})_2]_2$ $\text{CH}_2[\text{CBr}(\text{CO}_2\text{Et})_2]_2$ gives II and I. $[\text{CH}_2\text{CBr}(\text{CO}_2\text{Et})_2]_2$ and $\text{CHNa}(\text{CO}_2\text{Et})_2$ give $(\text{EtO}_2\text{C})_2\text{CH}(\text{CH}_2\text{CH}_2\text{CH}(\text{CO}_2\text{Et}))_2$ (IV) and III, while with

$[\text{CNa}(\text{CO}_2\text{Et})_2]_2$ $[\text{CH}_2\text{CBr}(\text{CO}_2\text{Et})_2]_2$ gives IV and I and with $[\text{CH}_2\text{CNa}(\text{CO}_2\text{Et})_2]_2$ there results only IV. The probable mechanism of these reactions is discussed. They can be correlated by the assumption of rapid bromination of substituted sodiomalonic esters by substituted bromomalonic esters, followed by slower double decompn. of the normal type with alkylvaln of malonic esters. In order to bring further evidence of the oxidizing action of Bresters contg. the α -bromo- α,α -dicarboxylic group, the action of $\text{CH}_2[\text{CBr}(\text{CO}_2\text{Et})_2]_2$ and of $[\text{CH}_2\text{CBr}(\text{CO}_2\text{Et})_2]_2$ on PhOH was investigated. In the 1st reaction, the PhOH was brominated and the product on hydrolysis gave *propane- α,α,γ -tricarboxylic acid*, m. 125° and loses CO_2 at $128-35^\circ$, giving glutaric acid; the latter gives adipic acid and brominated phenols. $\text{CH}_2[\text{CBr}(\text{CO}_2\text{Et})_2]_2$ and $\text{C}_{10}\text{H}_7\text{OH}$ in the presence of EtONa give II. $(\text{EtO}_2\text{C})_2\text{C}[\text{CH}_2\text{CNa}(\text{CO}_2\text{Et})_2]_2$ and $\text{BrCH}_2\text{CHBrCO}_2\text{Et}$ give *trans*-cyclopentane-1,2,4-tricarboxylic acid, the intermediate product being the 1,2,3,4,4-penta-carboxylate.

C. J. WEST

New method for the preparation of diphenyl oxalate and the dicresyl oxalates. JOSIP MIKŠIĆ AND ZVONIMIR PINTEROVIĆ. Univ. Zagreb. *J. prakt. Chem.* 119, 231-4 (1928).—PhOH (37 g.) in 200 cc. Et_2O , treated, with cooling, with 25 g. $(\text{COCl})_2$, in 50 cc. Et_2O and then with 9 g. Na wire and allowed to stand overnight, gives 10 g. $(\text{CO}_2\text{Ph})_2$, m. 134° ; similarly were prepd. the *o*-cresyl ester, m. $90-1^\circ$; the *m*-cresyl ester, m. 105° and the *p*-cresyl ester, m. 148° . Metallic K reacts in the same way, but the yields are better with Na.

C. J. WEST

Condensation of pyrrocemic acid with paraformaldehyde in the presence of sulfuric acid. V. FEOPILAKTOV. *J. Russ. Phys.-Chem. Soc.* 58, 759-66 (1926); *Chem. Zentr.* 1927, I, 418.—A continuation of previous work (cf. *C. A.* 21, 896). It was shown by Jankowa that "Kaltwasser's acid" yields a cryst. Ac deriv., a cryst. oxidation product with PbO_2 in AcOH and $(\text{CO}_2\text{H})_2$ with 1% KMnO_4 . In freezing AcOH the lactone has a mol. wt. of about 130, corresponding to $\text{C}_8\text{H}_6\text{O}_4$, in boiling AcMe the mol. wt. is 258-269, corresponding to $\text{C}_{11}\text{H}_{12}\text{O}_5$. From water it forms monoclinic crystals which lose water at about 90° . The *Ag salt* also readily loses 1 mol. of water. The "oxime" and the "di-Ac deriv." cannot be normal derivs. of the lactone because they contain about 2 and 1 mol. of water, resp., too few.

C. C. DAVIS

Synthesis of rutecarpine. III. Y. ASAHINA AND T. OHTA. *J. Pharm. Soc. Japan* 48, 313-7 (1928); cf. *C. A.* 21, 2134, 3054, 3622.—Previously A. and O. tried without success to obtain rutecarpine (I) by reduction of *N*-*o*-nitrobenzoyl-3-keto-3,4,5,6-tetrahydro-4-carboline (II) with SnCl_2 and HCl. Now they succeeded in obtaining I by treating II with glacial AcOH and Zn dust. Yield, 80%. It is to be noted that 3- β -aminoethylindole-2-carboxylic acid, the precursor of II, was previously obtained from I, but now has been obtained by treating 3-keto-3,4,5,6-tetrahydro-4-carboline (Manske and Robinson. *C. A.* 21, 1263) with EtOH-KOH. NAO UYRI

Anomalous rotatory dispersion from the standpoint of the Drude equation. CHAS. E. WOOD AND SYDNEY D. NICHOLAS. *J. Chem. Soc.* 1928, 1671-96.—Values for d. and rotations for many wave lengths are given for the following esters: Et tartrate, acetyl tartrate, diacetyl tartrate, benzoyl tartrate, dibenzoyl tartrate, thionyl tartrate, dichlorosuccinate, Me tartrate, acetyl tartrate, diacetyl tartrate, benzoyl tartrate and

dibenzoyltartrate. Examn. of the rotatory-dispersion curves for these compds. shows that both inflection and max. are confined to the positive region of rotation and crossing of the axis occurs in only 1 way, viz., as the wave length decreases so the rotation decreases, $da/d\lambda$ being always positive. The occurrence of anomalous rotatory dispersion is an indication of the relative configuration. The explanation of anomaly by consideration of ultra-violet terms only is incomplete. A view has been put forward postulating an infra-red term in the Drude equation. The term is negative for a compd. of relative configuration "d." This term, though its contribution may be small compared with rotation of electronic origin, is necessary, for it controls the assocn. of the high-frequency const. with the positive ultra-violet term and the final course of the path to the infra-red band in the positive region. The consideration of anomaly involves both the superposition rule (Lowry) and also Wood's interpretation of Drude's view of spurious anomaly; for the dispersion occurs between 2 bands, the low-frequency band in the ultra-violet and the infra-red band, and not merely outside the ultra-violet bands (longer wave length side), the infra-red band being neglected. Quartz is taken as an illustration of the importance of the infra-red term. By an extension of Thomson's view, a single asym. center can give rise to anomaly. Different classes of anomalous rotatory dispersion are discussed. C. J. WEST

Rotatory dispersion: Intersection of dispersion curves and of temperature-rotation curves. CHAS. E. WOOD AND SYDNEY D. NICHOLAS. Univ. of Birmingham. *J. Chem. Soc.* 1928, 1696-712.—The manner of intersection of dispersion curves is discussed. An envelope of max dispersion develops in certain tartrates and lactates, with increase of temp., in the direction red \rightarrow blue, which indicates movement of max. in temp-rotation curves. Movement of max of positive rotation (temp-rotation diagram) is in 1 direction only, provided the crossing of the axis, da/dT , is positive. A definite movement is of value in deciding configuration. It is necessary to know, in absence of anomaly, the direction of crossing the axis and the possibility of intersection of the temp-rotation curves in the positive region. Two methods throw light on these points—effect of solvents and extrapolation by means of a characteristic diagram. The presence and movement of negative min is assumed to be a temp relationship for enantiomorphs, and is of rarer occurrence than max of negative rotation. Utilization for configuration purposes depends upon a consideration of the following points: movement of minima; the sign of da/dT on crossing the axis; no intersection of temp-rotation curves in the negative region; effect of solvents. The possibility of 8 types of max. and min. having temp-rotation curves convex towards the axis is considered. Intersection of temp-rotation curves takes place in a definite order and gives rise to an enveloping curve of max. temp. rotation. C. J. WEST

Study of the anomalous rotatory dispersion of configuratively related compounds. CHARLES E. WOOD AND SYDNEY D. NICHOLAS. Univ. of Birmingham. *J. Chem. Soc.* 1928, 1712-27.—Anomalous rotatory dispersion is a trustworthy criterion for detg. relative configuration. The configuration of *l*-lactic, *l*-malic, *d*-hexahydro-mandelic and *d*-tartaric acids, as shown by their anomalies, are *d*, *l*, *l* and *d*, resp., which is in agreement with the configuration assigned to these acids by other workers. The non-empirical nature of this criterion is illustrated by *l*-alanine, *l*-tyrosine and *l*-aspartic acid, which are configuratively related to *l*-tartaric acid and certain series of alcs. The distinction between *d*- and *l*-alcs. contg. normal straight chains depends only on their relative lengths, since all other factors are eliminated. Movement of max. and min. for a particular wave length in a homologous series of configuratively related compds. is discussed. Series of alcs. have been considered with respect to: configuration; rotation changes with temp. for each individual member, particularly with regard to the region of approach of temp. rotation curves to the 0 axis and to a 0 rotation-temp-wave length plane; movements of max. and min. as the series is ascended. A series, none of the members (or derivs.) of which exhibits anomaly, is then considered with respect to temp-rotation curves and movement of max. and min., as the series is ascended. From analogy, conclusions are drawn as to configuration relationship. The configurations of nicotine and its salts are considered. C. J. WEST

Some acyl derivatives of hydrazine. F. J. WILSON, W. BAIRD, A. C. BROWN, E. C. PICKERING. *J. Roy. Tech. Coll. Glasgow*, No. 4, 60-2(1927).—Various aldehydic and ketonic derivs. of $\text{CO}(\text{NHNH}_2)_2$ were prepd. and their thermal decomps. studied. The following carbonylhydrazones of the type $\text{CO}(\text{NHN}:\text{CRR}')_2$ were prepd. from $\text{CO}(\text{NHNH}_2)_2$ and the resp. ketone: diacetone, di(methyl ethyl ketone), diacetophenone (I). Also some δ -aminosemicarbazones of the type $\text{NH}_2\text{NHCONHN}:\text{CRR}'$ were obtained (from $\text{CO}(\text{NHNH}_2)_2$ and the resp. aldehyde or ketone): benzaldehyde (II), acetophenone,

benzil and diacetyl. Ph_2CO and $\text{CO}(\text{NHNH})_2$ in boiling alc. gave *benzophenone δ -aminosemicarbazone*, which by prolonged boiling with excess of the ketone was partly transformed to $\text{CO}(\text{NHN}:\text{CPh})_2$ (cf. *Ber.* 37, 3177(1904)). A compd. of the mixed type is represented by the *benzaldehyde acetophenone carbohydrazone*, CH_3Ac_2 and $\text{CO}(\text{NHNH})_2$ gave 3,5-dimethylpyrazole, $\text{CO}(\text{NHIN}:\text{CHPh})_2$ (III) (cf. *J. prakt. Chem.* 52, 471(1895)) is decompd. in the following manner: boiling in abs. alc. gives dibenzaldehyde hydrazidicarbohydrazone (IV) and benzyldene azine (V); $2 \text{ III} = (\text{NH}:\text{CONHN}:\text{CHPh})_2$ (IV) + $(\text{PhCH}:\text{N})_2$ (V). IV and V were also obtained when III was heated at its m. p., but IV was further decompd. to 4-aminourazole, $\text{CO}:\text{NH}:\text{NH}:\text{CO}:\text{NNH}_2$ (VI), and V. Decompn. of I in boiling alc.: $2 \text{ I} = (\text{NH}:\text{CONHN}:\text{CMe}_2)_2 + (\text{PhMeC}:\text{N})_2$ (VII); without solvent. $2 \text{ I} = \text{VI} + 2 \text{ VII}$. Decompn. of II in boiling toluene: $\text{II} = (\text{NHCONHNH})_2 + \text{V}$; without solvent: $2 \text{ II} = \text{VI} + \text{NH}_2\text{NH}_2 + \text{V}$. Heating of $\text{CO}(\text{NHN}:\text{CMe}_2)_2$ with diphenylcarbohydrazone gave acetone phenylcarbohydrazone, VI, and $(\text{Me}_2\text{C}:\text{N})_2$, thus proving the interpretation of the thermal decompn. of some δ -anilinosemicarbazones (cf. *J. Roy. Tech. Coll. Glasgow*, No. 3, 89(1926)) to be correct. No intermediate products were obtained in the thermal decompn. of acetone, pinacolin and benzyldene δ -anilinosemicarbazone, while in the case of $\text{Me}_2\text{C}:\text{NNHCONHNHPh}_2$, some $\text{CO}(\text{NHNHPh})_2$ could be isolated. The reaction of PhNHNH_2 with acetone, acetophenone or dibenzyl ketone thiosemicarbazone, resp., gave thiosemicarbazide and the resp. ketonic phenylhydrazone instead of the expected δ -anilinothiosemicarbazone: $\text{CRR}':\text{NNHCSNH}_2 + \text{NH}_2\text{NHPh} = \text{CRR}':\text{NNHPh} + \text{NH}_2\text{NHCSNH}_2$. G. SCHWACH

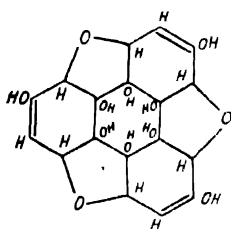

Chemistry of the three-carbon system. XVII. Cyclohexylideneacetone and cyclohexylenemethyl ethyl ketone. ALFRED H. DICKENS, WILFRED E. HUGH AND GEORGE A. R. KON. Imperial College Science Tech., London. *J. Chem. Soc.* 1928, 1630-8; cf. *C. A.* 22, 393.—The equil. mixt. of cyclohexylenemethyl Et ketone (I) and Δ^1 -cyclohexenylmethyl Et ketone (II) with an excess of EtONa contains 31% I; with insufficient EtONa, starting with I, the % of I was as follows: 3 hrs., 81; 8 hrs., 66; 16 hrs., 52.5; 24 hrs., 45; 48 hrs., 37; starting with II, the % of I was: 3 hrs., 10; 6 hrs., 20; 16 hrs., 30.5; 24 hrs., 31. With 10 cc. $\text{N}^2\text{H}_2\text{SO}_4$, after 16 hrs., I underwent about 75% conversion; II was unchanged, with piperidine, I was about 8.5% changed, II was again unchanged. In the direct condensation of cyclohexanone and MeCOEt, 84.5% II was formed. Condensation of II with $\text{CHNa}(\text{CO}_2\text{Et})_2$ gave the dihydroresorcinol ester as a viscous liquid, hydrolyzed with $\text{Ba}(\text{OH})_2$ to *cyclohexane-spiro-4-methylcyclohexane-3,5-dione*, m. 170°. Cyclohexylideneacetone (III) and Δ^1 -cyclohexenylacetone (IV), with excess of EtONa, give an equil. mixt. contg. 29% III; with insufficient EtONa, starting with III, the % of III decreased from 89% after 1 hr. to 34% after 46 hrs.; starting with II, the % of III increased from 12% after 3 hrs. to 26.5% after 24 hrs. With NaOH in EtOH, starting with III, the % of III decreases from 80.5 after 3 hrs. to 52.5% after 12 hrs.; starting with IV, the % of III after 6 hrs., 15; after 12 hrs., 22.5. C. J. WEST

Mechanism of tautomeric interchange and the effect of structure on mobility and equilibrium. II. Ring-chain tautomerism in its relation to the mutarotation of the sugars. JOHN WM. BAKER. Univ. of Leeds. *J. Chem. Soc.* 1928, 1583-93.—This paper contains a study of structural effects on ring-chain tautomerism in its application to the mutarotation of sugars. Tetraacetylglucose shows arrest of mutarotation in AcOEt for 23 hrs., and the mutarotation is not complete in 171 hrs.; tetramethylglucose shows a similar arrest in AcOEt and in Me_2CO for 6 and 3 hrs, resp. *Tetraacetylglucose anilide*, m. 98°; *p-toluide*, m. 147°; *p-aniside*, m. 129°; *p-bromoanilide*, m. 160°; *p-chloroanilide*, m. 147°; *N-methylanilide*, m. 102°. Details are given of the mutarotation of tetraacetylglucose in 90% EtOH and of the relative velocities of the anilides in AcOEt with acid catalysts at 24°. C. J. WEST

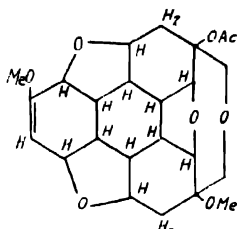

Methylation experiments on starch. LEOPOLD SCHMID AND MARGOT ZENTNER. Univ. Vienna. *Monatsh.* 49, 111-7(1928).—Methylation of starch with CH_3N_2 gives a product with about 21% MeO; hydrolysis with 1% MeOH-HCl by heating 46 hrs. at 100° and 12 hrs. at 170° gave a product, sepd. into 3 fractions with MeO 35.3, 25.23 and 20.01%. Further hydrolysis of the 1st fraction with aq. HCl gave a dimethylglucose, α_D 83.85°. Oxidation with HNO_3 gives a mono- CO_2H acid, whose Me ester contains 3 MeO groups. Hydrolysis of the fraction contg. 25.23% MeO gave a sugar with about 24% MeO. C. J. WEST

The status of lignin research. K. G. JONAS. *Papier-Fabr.* 26, 221-9(1928); cf. *C. A.* 15, 3063; 16, 2315; 19, 3015.—An address. The work of Klason, Fischer, and others, who ascribe an aromatic origin to lignin, is discussed and criticized. J.

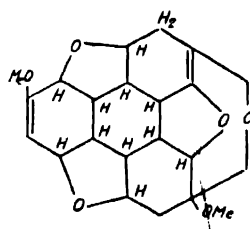

believes it to be a furan deriv. formed by polymerization and condensation of 3 mols. of 2,5-anhydrohexose, giving the compd. (I), $C_{15}H_{18}O_8$. Reduction of the OH groups in the inner ring may give rise to different lignins. I differs from Schrauth's formula (C. A. 17, 2111) in the position of the enolic OH groups. Native lignin is assigned the

I

II

III

structure II, $C_{20}H_{22}O_8$, and Willstätter lignin III, $C_{20}H_{22}O_8$. Condensed anhydro-sugars resembling III, but without the McO group, have been prepd. From the practical standpoint, such a lignin would be much more difficult to utilize commercially than if it were aromatic in nature.

R. H. DOUGHTY

Cryoscopic determination of the molecular weight of glycogen in liquid ammonia. LEOPOLD SCHMID, ERNST LUDWIG and KATHE PIETSCH. Univ. Wien. *Monatsh.* 49, 118-21 (1928).—A sample of Schuchardt's "Glykogen puriss," with 0.48% ash and α 175.3°, was almost completely sol. in liquid NH_3 ; a 2nd sample, with α 163° and 2.68% ash, was only partially sol., the recovered part having α 177°; a sample prepd. from human liver likewise was only partly sol., the recovered part having α 186°. The mol. wt. of the NH_3 -sol glycogens in liquid NH_3 was about 180 (range of values, 131-197).

C. J. WEST

Mobile hydrogen tautomerism analogous to the Wagner-Meerwein rearrangement. II. The tautomerism of 1 (or 5)-hydroxy-2,2,3,3-tetramethylcyclopentan-5(or 1)-one and its derivatives. CHARLES WM. SHOPPÉE. Univ of Leeds. *J Chem Soc.* 1928, 1662-70; cf. C. A. 22, 1952.—Reduction of bromoacetoxyphorone with Zn and AcOH gives mainly the Ac deriv., b_{10} 120.1°, of 1(or 5)-hydroxy-2,2,3,3-tetramethylcyclopentan-5(or 1)-one (I), m. 142°. It is but slowly oxidized with alk. $KMnO_4$ but reduces Fehling soln. readily; $EtOH-FeCl_3$ gives no color; *p*-nitrophenylhydrazone, golden yellow, m. 223-4° (decompn.); *p*-nitrobenzoate, m. 85°. Reduction of I gives a mixt of 2,2,3,3- and 3,3,4,4-tetramethylcyclopentanones, sep'd as the semicarbazones. $BzCl$ in C_6H_5N gives a mixt. of 2 Bz derivs, sep'd. by crystn. from dil. MeOH, 1-benzoyloxy-2,2,3,3-tetramethylcyclopentan-5-one, m. 105°, which reduces Fehling soln. and is hydrolyzed to I by NaOH; the oxime, m. 115°, gives no color with $FeCl_3$, reduces Fehling soln. on boiling, yields a Bz deriv., m. 135° and on reduction gives 3,3,4,4-tetramethylcyclopentylamine, m. 100°. 5-Benzoyloxy-2,2,3,3-tetramethylcyclopentan-1-one, m. 60°, hydrolysis gives I; the oxime is oily and gives a Bz deriv., b_{16} 200-15°; reduction of the oxime gives 2,2,3,3-tetramethylcyclopentylamine. The oximes of I form an oil which on reduction gives the 2 amines obtained from the Bz deriv. I with Me_2SO_4 gives a Me deriv., b_{16} 88-90°, n_D^{20} 1.4574; the oxime is oily.

C. J. WEST

Condensation of ketones with ethyl acetoacetate. LEONARD G. JUPP, GEORGE A. R. KON and EDWARD H. LOCKTON. Imperial College Science Tech., London. *J. Chem. Soc.* 1928, 1638-44.—Condensation of cyclohexanone with $AcCHNaCO_2Et$ by heating for 24 hrs. gives cyclohexenylacetone, cyclohexenylcyclohexanone and a very small quantity of the ester $C_6H_5CH(COMe)CO_2Et$, b_{16} 135°, giving an intense red-violet color with $FeCl_3$; semicarbazone, m. 141°; there also is formed cyclohexenylacetoacetic acid, m. 121°; semicarbazone, m. 196°; oxidation of this acid gives $(CO_2H)_2$ and adipic acid; heating splits off CO_2 and gives a mixt. of cyclohexylideneacetone and cyclohexenylacetone. The acid cannot be esterified. Other efforts to prep. the desired ester failed. Di-Et Δ^1 -cyclohexenylacetylmalonate, b_{16} 181°; semicarbazone, m. 178°; EtONa gives AcOEt and di-Et cyclohexenylmalonate. Condensation of cyclopentanone with $AcCHNaCO_2Et$ gives cyclopentylideneacetoacetic acid, m. 137° (decompn.). Et isopropylideneacetoacetate gives a semicarbazone, m. 247°; attempts to methylate the ester failed. Δ^1 -Pulegenylacetone (I) forms a semicarbazone, m. 187°; Na and MeI give the α -Me deriv., b_{16} 150°, d_4^{21} 1.49694, n_D^{21} 1.49347; semicarbazone, m. 191°. I and $AcCHNaCO_2Et$ give a dihydroresorcinol deriv., $C_{10}H_{12}O_3$, m. 130°;

FeCl_3 gives a reddish violet color. Piperitone gives a *ketone*, b_{20} 155 d_{20}^{21} 0.95821, n_D^{21} 1.49610; *semicarbazone*, $\text{C}_{14}\text{H}_{22}\text{ON}_3$, m. 217° C. J. WEST

Action of bromine water on certain olefinic hydrocarbons and ethers. JOHN READ AND WM. G. REID. Univ. of St. Andrews *J. Chem. Soc.* 1928, 1487-93.— PhCH:CH_2 and 7% Br in 10% KBr at 90° give 96.7% of β -hydroxy- β -phenylethyl bromide (I), b_2 109-10°, d_4^{20} 1.4994, n_D^{17} 1.5800; at ordinary temps., the yield drops to 78%, some dibromide being formed. I and concd. NH_4OH , shaken 10 hrs., give $\text{HOCHPhCH}_2\text{NH}_2$. Attempts to prep. I from the dibromide by digestion with CaCO_3 in aq. EtOH or Me_2CO were unsuccessful. The yields of bromohydrin from $\text{MeCH:CHC}_6\text{H}_4\text{OMe}$ at room temp. and 90° were 47.9 and 76.1%, resp. With concd. NH_4OH this gives β -hydroxy- β -*p*-methoxyphenylisopropylamine (II), m. 84° (*HCl* salt, m. 182°; *Bz* deriv., m. 159°; benzylidene deriv., viscid sirup). Crystn from abs. EtOH gives the *d*-II *d*-camphorsulfonate, m. 194-5°, $[\alpha]_D$ 20.5°; the *d*-II, m. 80-1°, $[\alpha]_D$ 4.6° (H_2O , c 1.0), 13.9° (MeOH , c 1.0), 18.4° (EtOH, c 0.6), 22.9° (C_6H_6 , c 1.2), 21.7° (Me_2CO , c 0.6). *HCl* salt, m. 171-2°, $[\alpha]_D$ 14.7° (H_2O , c 0.9); *Bz* deriv., m. 153-4°; a 0.5 EtOH soln. was inactive. The yields of bromohydrin from safrole at room temp. and 90° are 65.2 and 69.2%; from isosafrole, 67 and 72.8%; eugenol and isoeugenol give indefinite tarry products. β -Amino- α -hydroxydihydroisosafrrole, viscid oil; *HCl* salt, m. 154°. Amylene (chiefly $\text{Me}_2\text{C:CHMe}$) gives 50% of $\text{Me}_2\text{C(OH)CHBrMe}$, b_{15} 45-6°; concd. NH_4OH gives γ -amino- β -hydroxy- β -methylbutane, pale yellow, b_{15} 60-2°; chloroplatinate, orange, m. 186° (decompn.); *Bz* deriv., oily; *p*-nitrobenzoyl deriv., m. about 65°; *d*- α -bromocamphorsulfonate, m. 170°; *d*-camphorsulfonate, m. 144°; no optical resolution was noted on crystn. of these salts. With KOH the bromohydrin gives trimethylene oxide, while on heating with H_2O at 100° or with PbO_2 and PbCl_2 , Me_2CHAc results, *dl*- Δ^3 -Menthene and Br in H_2O give a mixt. of $\text{C}_{10}\text{H}_{17}\text{OBr}$ and $\text{C}_{11}\text{H}_{17}\text{Br}_2$, amber-colored liquid, which decomp. on distn, n_D 1.5111. C. J. W.

The halogenation of aromatics in aqueous solutions. D. V. TISHCHENKO. *J. Russ. Phys.-Chem. Soc.* 60, 153-62(1928).—A concd. soln. of Na_2CO_3 and 1 equiv. Br_2 give NaHCO_3 , NaBr , Br_2 , NaBr and NaBrO_3 . In dil. solns. contg. excess Na_2CO_3 , NaOBr is found. Into 0.1 mol. org. substance dissolved or suspended in 50 cc. H_2O are allowed to drop 0.1 mol. of Br_2 and Na_2CO_3 in 100 cc. H_2O ; 0.05 equiv. of HCl or H_2SO_4 are added after the mixt. is colorless. Evolution of Br_2 and CO_2 follows, and bromination stops. PhH , PhMe and xylenes are unchanged, C_{10}H_8 gives 80% very pure α - $\text{BrC}_6\text{H}_4\text{H}$; which is not colored on standing. PhOH yields over 70% *p*- $\text{BrC}_6\text{H}_4\text{OH}$; 20 g. Br_2 , 36 g. Na_2CO_3 and 4 g. PhOH give $\text{Br}_2\text{C}_6\text{H}_3\text{OH}$ quant. *m*-($\text{HO})_2\text{C}_6\text{H}_4$ is partly oxidized, 15% $\text{Br}_2\text{C}_6\text{H}_3(\text{OH})_2$ m. 111° (*Monatsh* 9, 296, 1888) being obtained. β - $\text{C}_{10}\text{H}_7\text{OH}$ forms tar which settles on careful addn. of acid; 1.2- $\text{C}_{10}\text{H}_7\text{BrOH}$ in the soln. is recrystd., yield, 60%. *o*- and *p*- $\text{C}_6\text{H}_4(\text{OH})_2$ are almost wholly resinified. The *m*- and *o*-cresols yield 84 and 70%, resp., of 6-*Br* deriv.; *p*-cresol gives 60% of $\text{Br(OH)C}_6\text{H}_4\text{Me}$ b_{15} 110-4°. Alizarin and anthraquinone are not acted on; indigo is oxidized to indoxyl. BrONa and $\text{C}_6\text{H}_4(\text{CO}_2\text{Na})_2$ are not brominated. *o*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{Na}$ after bromination was converted into the *Ca* salt and crystd. The middle fraction (70% of the total) gave 4.2- $\text{Br(HO)C}_6\text{H}_3\text{CO}_2\text{H}$. PhOH forms *p*- and $\text{MeC}_6\text{H}_4\text{OH}$, *o*-derivs. in solns. of the same acidity. On the other hand, the brominating agent must be Br_2 in acid and HOBr in alk. solns. since almost quant. bromination of *m*- $\text{C}_6\text{H}_4(\text{OH})_2$ occurs in the former and oxidation in the latter. Analogous expts. were made with Cl_2 instead of Br_2 . PhOH gives equal quantities of *o*- and *p*- $\text{ClC}_6\text{H}_4\text{OH}$, the total yield being 75%. *o*-Cresol yields 80% of *m*- and *o*- Cl derivs., *m*-cresol gives chiefly 2,3- $\text{ClMeC}_6\text{H}_3\text{OH}$ besides the *p*- Cl deriv. Thymol yields 80% of a 4- Cl deriv., m. 59-60° and b. 259-43°. *m*- $\text{C}_6\text{H}_4(\text{OH})_2$ is strongly oxidized; β - $\text{C}_{10}\text{H}_7\text{OH}$ gives 20% of what is probably 2,8- $\text{C}_{10}\text{H}_6(\text{OH})\text{Cl}$, m. 101°, and 30% of β , β - $\text{C}_{10}\text{H}_6(\text{OH})_2$, besides a tarry residue. PhNH_2 is transformed into $\text{H}_2\text{NC}_6\text{H}_4\text{NO}_2$. PhNMe_2 yields about 100% of the *o*- and *p*- Cl derivs. in equal quantities. AcNHPh , acetotoluides acetonaphthalides, Ph_2NH and α -aminoanthraquinone are not changed. $\text{H}_2\text{NC}_6\text{H}_4\text{SO}_3\text{Na}$ is converted into yellow ($\text{NC}_6\text{H}_4\text{SO}_3\text{Na})_2$, which yields $\text{H}_2\text{NC}_6\text{H}_4\text{SO}_3\text{H}$ with Sn in HCl . The salts of the CO_2H and SO_3H which do not contain OH , NH_2 , etc., groups are not chlorinated. The chlorination products of *o*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{Na}$ were a mixt. of *p*- and *o*-derivs. *p*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{Na}$ gives the *m*- Cl deriv. quant. Alk. solns. of Cl_2 thus have a stronger oxidizing action than those of Br_2 due to the greater content of hypohalite.

BASIL C. SOYENKOFF

The influence of impurities on the reaction velocity of organic halides with amines. B. V. TRONOV AND A. I. GERSHEVICH. *J. Russ. Phys.-Chem. Soc.* 60, 171-80(1928).—Equimol. quantities of PhCH_2Cl , $\text{C}_6\text{H}_5\text{N}$ and a hydrocarbon or alc., etc., were allowed

to react at 18°, extd. with H_2O , and the halogen ion titrated. Hydrocarbons and Et_2O hindered the reaction between PhCH_2Cl and $\text{C}_6\text{H}_5\text{N}$. Aldehydes, ketones, esters and PhNO_2 had little influence. $\text{CH}_2(\text{NO}_2)_2$ accelerated the reaction 1.5-2.2 times, alcs. 1.5-2.8 times, MeCN 1.79 times and $\text{MeCH}(\text{OH})\text{CN}$ and HCONH_2 about 5 times. Similar results were obtained with PhCH_2Br and CCl_4NO_2 . Substances which cause $\text{C}_6\text{H}_5\text{N}\cdot\text{HCl}$ to sep. hinder the reaction, possibly because $\text{C}_6\text{H}_5\text{N}$ is carried down with the salt. However, the immiscible substances are also chem. inert while those in which $\text{C}_6\text{H}_5\text{N}\cdot\text{HCl}$ is sol. form complexes. HCONH_2 , although immiscible, accelerates the reaction, probably by forming a complex with $\text{C}_6\text{H}_5\text{N}$.

BASIL C. SOYENKOFF

The preparation of *p*-nitrobenzyl bromide. I. V. HOPPER. *J. Roy. Tech. Coll. Glasgow*, No. 4, 58-9 (1927).—Improved methods are given for the prepn. of *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{CH}_2\text{Br}$ (I). By heating 5 g. of *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{Me}$ with 2 cc. Br at 128-32° in a sealed tube for 160 min., 70% of I was obtained. Addn. of a crystal of I raised the yield to 80%. Heating of 10 g. *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{Me}$ with 12.7 g. Br and an I crystal in CCl_4 under reflux and while exposed to the rays of a mercury-vapor lamp, gives 80% of I.

G. SCHWOCH

The action of magnesium on *p*- and *m*-dibromobenzene. Y. S. ZALKIND AND P. V. RAGOVINA. *J. Russ. Phys. Chem. Soc.* 59, 1013-8 (1927).—On the basis of electronic structure of the dibromobenzenes (according to Berkenheim) the introduction of Mg would strengthen the C-Br linkage in the *p* position and weaken it when in the *m*-position. The reactivities of *m*- and *p*- $\text{Br}_2\text{C}_6\text{H}_4$ were detd. by adding them to 2 equivs. Mg in abs. Et_2O . After 9 hrs. boiling the Mg compd. was decompd. with ice H_2O and uncombined Mg dissolved in dil. H_2SO_4 . The vols. of H_2 were measured and the aqueous layers titrated for Br. The *m*-deriv. reacted with 83.0, 87.0, 87.1% Mg, the *p*-deriv. with 88.4, 86.6, 88.0%. The figures obtained by Br titration are higher because the Fittig condensation also takes place. Among the reaction products of *m*- $\text{Br}_2\text{C}_6\text{H}_4$ were PhH (yield 30.8%) and PhBr (22.6%) besides a small amt. of Ph $_2$ and tar contg. 11.2% Br. An expt. with Mg, activated with 50% I_2 , and *p*- $\text{Br}_2\text{C}_6\text{H}_4$ showed that 83% of Mg entered the reaction. A 23% yield of PhH was obtained besides 24% PhBr, some (*p*- BrC_6H_4) $_2$ and tar. The *m*- and *p*-derivs. thus react equally readily with the second Mg, any resulting Mg_2 compds. being transformed into tar.

BASIL C. SOYENKOFF

Nitration of benzene to mononitrobenzene. V. I. MALYAREVSKII AND I. P. KALINCHENKO. *J. Chem. Ind. (Moscow)* 4, 399-500 (1927).—A series of expts. with nitrating mixts. consisting of 38.5% HNO_3 , 48.7-54.37% H_2SO_4 , 12.8-7.13% H_2O , as well as with those having the following compos.: HNO_3 34.1%, H_2SO_4 52.6%, H_2O 13.74%; HNO_3 28.69%, H_2SO_4 56.45%, H_2O 14.86%; HNO_3 23.05%, H_2SO_4 60.90%, H_2O 16.05%, the temps. of nitration being 40°, 50°, 60°, 70°, 80°, show that the compn. of the nitrating mixt. within the limits studied, and particularly the temp. of the reaction, have but an insignificant influence on the quality of the PhNO_2 obtained, the formation of $\text{C}_6\text{H}_4(\text{NO}_2)_2$ as impurity varying only between 0.03 and 0.20%. While only an insignificant amount of $\text{C}_6\text{H}_4(\text{NO}_2)_2$ is formed as long as an excess of benzene is present in the mixt., the formation of larger quantities of $\text{C}_6\text{H}_4(\text{NO}_2)_2$ and their increase with the rise of the temp. are principally due to a partial overnitration which takes place at the end of the operation when very little benzene is left. Another factor which may bring about the formation of $\text{C}_6\text{H}_4(\text{NO}_2)_2$ is the insufficient stirring of the reaction mixt. It is advisable to operate with energetic stirring of the mixt., or with a nitrating app. of such construction that the nitrating liquid, at the moment of entering the app. does not immediately come in contact with the benzene. Since the temp. of nitration can be raised to 80°, and probably higher, without lowering the quality of the product obtained, it is advisable to operate at this high temp., thus increasing the speed of the reaction. The higher the temp. the more completely HNO_3 is utilized, and thus smaller amounts of it could be taken, which in turn would permit operation with smaller amounts of H_2SO_4 .

BERNARD NELSON

Catalytic oxidation of nitro and halogen derivatives of toluene by means of air. EDWARD B. MAXTED AND ARTHUR N. DUNSBY. *J. Chem. Soc.* 1928, 1439-42; cf. C. A. 22, 2376.—Oxidation of *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{Me}$ to *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ by air in the presence of Sn vanadate begins at 260° (8.4% yield); at 270-300° the yield is fairly const. at 14-16%; the air rate was 10 l. per hr., about 0.3 g. *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{Me}$ passing the 10 cc. of catalyst during that time. *o*- $\text{O}_2\text{NC}_6\text{H}_4\text{Me}$ gave little or no acid, the product decompd. at catalyst temps. sufficient to cause oxidation. *o*- $\text{BrC}_6\text{H}_4\text{Me}$ gives 7.4% acid at 255°, 12.1% at 265°, 13.7% at 275°, 21% at 285°, 24.3% at 290°, 14% at 295° and 6.3% at 305°. *o*- $\text{ClC}_6\text{H}_4\text{Me}$ gives 4.9% acid at 260°, 7.4% at 275°, 13% at 285°, 13.8% at 287° and 12.6% at 293°.

C. J. Waser

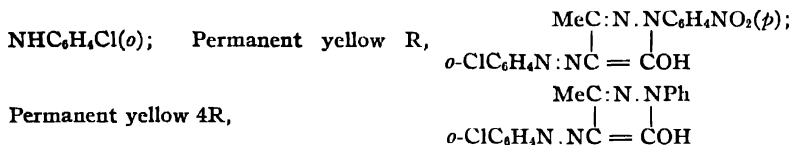

α , γ -Diamino- β -phenylpropane and related compounds of pharmacological interest. JOSEPH G. JACKSON AND JAMES KENNER. Univ. of Sheffield. *J. Chem. Soc.* 1928, 1657-62.—*Di-Et β -phenylglutarate* b_{14} 180-4°; *β -phenylglutardihydrazide* m. 177°; the corresponding urethan m. 73-4°; with boiling HBr (6 hrs.) this gives α , γ -diamino- β -phenylpropane-HBr (I), m. 252° decomps. 272°; the free base, b_{15} 150°, is rapidly converted into the carbonate, m. 172° (decompn.), in the air; *picrate*, yellow, m. 247° (decompn.); *di-Ac deriv.*, m. 153-4°; *di-Bz deriv.*, m. 179°; *di-p,p'-toluenesulfonyl deriv.*, m. 91° (Me₂SO₄ gives a *di-Me deriv.*, m. 60°, whose acid hydrolysis gives *N,N'*-dimethyl- α , γ -diamino- β -phenylpropane-HCl, m. 249°). The filtrate of I gives γ -amino- β -phenylbutyric acid-HBr, m. 114°, which, treated with cold 10% KOH, gives 4-phenyl-2-pyrrolidone, m. 60° (*Ac deriv.*, m. 63°; *Bz deriv.*, m. 145°). The di-Ac deriv. of I and P₂O₅ in PhMe gives 4-aminomethyl-1-methyl-3,4-dihydroisoquinoline (II), m. 182° (*HCl salt*, m. 222°); the di-Bz deriv., similarly treated, gives the *Bz deriv.*, m. 114°, of 4-aminomethyl-1-phenyl-3,4-dihydroisoquinoline (III), m. 169° (*di-HCl salt*, m. 291°). CH₂(CO₂Et)₂ and *p*-MeC₆H₄CH₂CHCO₂Et with EtONa give tri-Et *p*-methoxyphenylpropane- α , α , γ -tricarboxylate, b_{12} 225-40°; hydrolysis and heating the resulting acid at 130° gives β -*p*-methoxyphenylglutaric acid, m. 165°; *anhydride*, m. 152°; *di-Me ester*, m. 42°, b_{20} 205-10°; *di-Et ester*, b_{14} 206-10°; *dihydrazide*, m. 190°; *diurethan*, m. 99-100°; hydrolysis with HBr gives α , γ -diamino- β -*p*-hydroxyphenylpropane-di-HBr (IV), m. 316°, which gives a violet color with FeCl₃; *tri-Bz deriv.*, m. 206-7°. Heating veratraldehyde, CH₂(CO₂H)₂ and 4 *N* EtOH-NH₂ at 100° for 6 hrs. gives 3,4-dimethoxybenzylidenemalonic acid, light yellow, m. 208° (decompn.). Tri-Et β , β ,4-dimethoxyphenylpropane- α , α , γ -tricarboxylate, b_{14} 245-8°; 3,3'-dimethoxydiphenylglutaric acid, crystg. with 1 H₂O, m. 125-30°; *anhyd.*, m. 184°; *anhydride*, m. 124°; *di-Me ester*, m. 73°; *di-Et ester*, b_{15} 226-9°; *dihydrazide*, m. 182°; the sirupy urethan, on hydrolysis with HBr, gives α , γ -diamino- β ,3,4-dihydroxyphenylpropane-di-HBr (V), crystg. with 1 H₂O, m. (anhyd.) 294°; *tetra-Bz deriv.*, m. 217°. I and its di-Me deriv. produce no appreciable effect upon the blood pressure of a cat; IV and V are devoid of all but a trace of a sympathomimetic action. II and III cause a definite depression of the blood pressure of a cat.

C. J. WEST

Identification of the reduction products of azo dyes. II. Classification and identification of compounds belonging to group A. SHIGEO UENO. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 49-88 (1928); English Ed. 1, 3-5.—In the first paper, U. had classified the reduction products of azo dyes into 2 groups. Group A: Those which show a color reaction with difficulty through oxidation by air. when a filter paper is moistened with their NH₄OH soln.; Group B: Those giving a color reaction. Some 80 compds. belonging to group A have been classified as follows: *Class I*.—Easily distd. by steam: aniline, *o*- and *p*-toluidines, *m*- and *p*-xylydines, γ -cumidine, *o*- and *p*-anisidines, *p*-phenetidine, 2,4-Cl₂C₆H₃NH₂, 3,4-H₂N(MeO)C₆H₃Me. *Class II*.—Distd. by steam rather poorly, but easily identifiable: *m*- and *p*-C₆H₄(NH₂)₂, *m*-tolylenediamine, α - and β -C₁₀H₇NH₂.—*Class III*.—Bases difficultly sol. in water: benzidine, *o*- and *m*-tolidines, dianisidines, 3-ethoxybenzidine, 3,3'-dichlorobenzidine, *p*-H₂NC₆H₄NHPh, (*p*-H₂NC₆H₄)₂NH, thioaniline, (*p*-H₂NC₆H₄NH)₂CO, (*p*-H₂NC₆H₄NH)₂CS, dehydrothio-*p*-toluidine, dehydrothio-*m*-xylydine, 1,4-C₁₀H₆(NH₂)₂NHPh. *Class IVa*.—Bases moderately sol. in water: 3,4-H₂N(PhCH₂O)C₆H₃Me, 1,3,4,5-C₆H₂Me₂(NH₂)₂, 2-aminobenzidine, 1,2-C₁₀H₆(NH₂)₂. *Class IVb*.—Bases easily sol. in water: 3,4-(H₂N)₂-C₆H₃Me, *m*-H₂NC₆H₄NMe₂Cl, *p*-H₂NC₆H₄CH₂NMe₂, *p*-H₂NC₆H₄CH₂NH₂. *Class V*.—Free acids difficultly sol. in water, sepp. out on addn. of dil. HCl to aq. solns. of their alk. salts: 2,5,4-Cl(H₂N)(HO₂S)C₆H₃Me; benzidine-2,2'- and 3,3'-disulfonic acids; diaminostilbenedisulfonic acid; diaminodiphenylureadisulfonic acid; 4,4'-diaminodiphenylamino-2-sulfonic acid; dehydrothio-*p*-toluidinesulfonic acid; 1,4- and 1,5-C₁₀H₆(NH₂)₂SO₃H, 2,1-, 2,5-, 2,6- and 2,8-C₁₀H₆(NH₂)₂SO₃H, 1,5,3,7-C₁₀H₄(NH₂)₂(SO₃H)₂, 2,5,7-C₁₀H₄(NH₂)₂(OH)(SO₃H). *Class VIa*.—Free acids or their acid Na salts slightly sol. in water: metanilic acid; sulfanilic acid; 4,2- and 4,3-H₂N(HO₂S)C₆H₃Me; 4-amino-*m*-xylene-5- and 6-sulfonic acids; 2,4-H₂N(HO₂S)C₆H₃OH, 1,2,3,4,6-C₆H₃(NH₂)₂(SO₃H)₂, 1,4,7-, 1,4,8-, 2,1,6- and 2,3,6-C₁₀H₆(NH₂)₂(SO₃H)₂, 8,3,6-C₁₀H₄(OH)(SO₃H)₂. *Class VIb*.—Free acids or their acid Na salts easily soluble in water (more than 2% at ordinary temp., acidic Na salts diminishing their soly. very greatly on addn. of NaCl to the solvent): 2,5-H₂N(HO₂S)C₆H₃Me, 2,4- and 2,5-(HO₂S)₂C₆H₃NH₂; 1,3,6-, 1,4,6-, 2,6,8-C₁₀H₆(NH₂)₂(SO₃H)₂. *Class VII*.—Difficultly sol. in water, sol. in dil. AcOH, sepp. out on addn. of NaHCO₃ to the aq. soln. of their chlorides, easily sol. in alk. carbonates: *p*-aminophenol; 5,2- and 3,4-H₂N(OH)C₆H₃Me. *Class VIIa*.—Free acids slightly or difficultly sol. in water, aq. soln. of their HCl salts sepp. out as free acids on addn. of AcONa: *o*-, *m*-, and *p*-H₂NC₆H₄CO₂H, 3,2- and 5,2-

$\text{H}_2\text{N}(\text{HO})\text{C}_6\text{H}_4\text{CO}_2\text{H}$. *Class VIIIb*.—Slightly or difficultly sol. in water, their HCl salts sepg. mostly as free acid even without adding AcONa : 3,5,2- and 4,5,2- $\text{Me}(\text{H}_2\text{N})(\text{HO})\text{C}_6\text{H}_3\text{CO}_2\text{H}$. A. L. HENNE

Constitution of Hansa yellow 3G, 5G and log (M. L. B.) and of permanent yellow R and 4R (A. G. F. A.). A. H. BURR AND F. M. ROWE. *J. Soc. Dyers Colourists* **44**, 205-7(1928).—Analytical and synthetical reactions indicated the following constitutions: Hansa yellow 3G, 4,2- $\text{Cl}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{N}:\text{NCHAcCONHPh}$; Hansa yellow 5G, $\alpha\text{-O}_2\text{NC}_6\text{H}_4\text{N}:\text{NCHAcCONHPh}$; Hansa yellow 10G, 4,2- $\text{Cl}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{N}:\text{NCHAcCO}$ -

L. W. RIDGS

The transformation of diaminodiphenylarsinic acid into the diphenylarsinic acid. V. V. NEKRASOV. *J. Russ. Phys.-Chem. Soc.* **59**, 877-80(1927).—($p\text{-H}_2\text{NC}_6\text{H}_4$)₂AsO(OH) (I) is a by-product in the prepn. of arspenamine. $\text{Ph}_2\text{AsO}(\text{OH})$ can be obtained from it and used in the AsPh_2Cl synthesis. The crude I is extd. from the residues and charcoal thrice with the same portion of H_2O which is cooled and filtered each time. A soln. of 29 g. of the acid in 45 cc. HCl (d. 1.14) and 100 cc. H_2O is diazotized with 14 g. NaNO_2 in 70 cc. H_2O at 0-2°. The reaction mixt. is added to a cooled soln. of 106 g. $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$ in 112 cc. HCl (d. 1.14) and 180 cc. H_2O to which 2-3 cc. 10% CuSO_4 has been added. The mixt. is left overnight, neutralized, boiled with charcoal and filtered. The residue is extd. as above. $\text{Ph}_2\text{AsO}(\text{OH})$, m 173-4°, seps. on cooling. Yield 15-16 g. BASIL C. SOYENKOFF

Arylsulfonyl chlorides. II. ERICH GEBAUER-FULNEGG, EUGEN RIESZ AND SIEGFRIED ILSE. *Univ. Wien Monatsch.* **49**, 41-6(1928); cf. *C. A.* **21**, 573.—The action of NaI upon $p\text{-MeC}_6\text{H}_4\text{SO}_2\text{Cl}$ gives $p\text{-MeC}_6\text{H}_4\text{SO}_2\text{Na}$, identified as the free acid, ($p\text{-MeC}_6\text{H}_4\text{SO}_2$)₂, m. 212°, and $p\text{-MeC}_6\text{H}_4\text{SO}_2\text{SC}_6\text{H}_4\text{Me}(p)$, m. 78°. $\text{PhC}_6\text{H}_4\text{SO}_2\text{Cl}$ and NaI give $\text{PhC}_6\text{H}_4\text{SO}_2\text{Na}$ (the free acid m. 71°) and *dibiphenyldisulfone*, m. 214-6°. C. J. WEST

Course of the oxidation of arylsulfurarylides. ERICH GEBAUER-FULNEGG AND EUGEN RIESZ. *Univ. Wien. Monatsch.* **49**, 31-40(1928), cf. *C. A.* **22**, 1148.—Five g. each of 4,2- $\text{Cl}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{SOCl}$ and $o\text{-H}_2\text{NC}_6\text{H}_4\text{OH}$ in Et_2O give 6.5 g. of 4-chloro-2-nitrophenylsulfur-2'-hydroxyanilide, reddish brown, m. 143°; oxidation with $\text{Na}_2\text{Cr}_2\text{O}_7$ in AcOH gives an amorphous product, m. 134-5°; H_2O_2 gives 4-chloro-2-nitrophenyl-o-quinone sulfur imine, $\text{Cl}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{SN}:\text{C}_6\text{H}_4:\text{O}$. $p\text{-C}_6\text{H}_4(\text{NH}_2)_2$ gives sym-bis-[4'-chloro-2'-nitrobenzenesulfenyl]-1,4-diaminobenzene, m. 212°, all oxidizing agents, as well as long boiling with AcOH or Me_2CO , give a high-melting, very difficultly sol., red product; 1 amorphous product m. 264-70°; continued boiling with AcOH gives a violet product, m. 212°; chlorination of the high-melting product gives NH_4Cl and $\text{Cl}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{SOCl}$. $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$ gives the corresponding 1,2-diaminobenzene, red, m. 181°; also, a 2,3-diaminophenazine, yellow, decomps. above 340°. Oxidation of the former gives a dark violet product, m. 187-93°; long boiling with AcOH gives a reddish brown ppt. $p\text{-Me}_2\text{NC}_6\text{H}_4\text{NH}_2$ gives 1-dimethylamino-4-[4'-chloro-2'-nitrobenzenesulfenyl]aminobenzene, brownish red, m. 152°. Oxidation with HNO_3 gives the compd. $\text{C}_{14}\text{H}_{13}\text{O}_2\text{N}_3\text{SCl}$, red, m. 102°; the free base, $\text{C}_{14}\text{H}_{14}\text{O}_2\text{N}_3\text{S}$, m. 186° ($\text{Cl}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{SN}:\text{C}_6\text{H}_4:\text{NMMe}_2\text{OH}$). C. J. WEST

Direct introduction of substituents into aromatic mercaptans. Complementary note. TH. VAN HOVE. *Ghent Univ. Bull. soc. chim. Belg.* **37**, 240(1928).—A correction to the bibliography of *C. A.* **22**, 62. A. L. HENNE

Oxidation of sulfides by benzoylhydroperoxide. II. I. N. LEWIN. Nametkin's Lab., Moscow. *J. prakt. Chem.* **119**, 211-4(1928); cf. *C. A.* **22**, 1950.—(ClCH_2CH_2)₂S (2.52 g.) in 50 cc. CHCl_3 , cooled to -10° and treated with the theoretical quantity of BzO_2H in CHCl_3 , also at -10°, gives quant. the sulfoxide, m. 108.5-10.5°; Ph_2S is likewise quant. oxidized to the sulfoxide, m. 70-1.8°; (PhCH_2)₂S gives the sulfoxide, m. 133-4.6°. With an excess of BzO_2H , the corresponding sulfones are formed, quant. in the 1st 2 cases, 80% in the case of (PhCH_2)₂SO. C. J. WEST

Organoselenic compound. M. TAKAMATSU. Tokyo Imp. Univ. *J. Pharm. Soc. Japan* **48**, 450-3(1928).—Heating of 2 mols. PhOH and 1 mol. H_2SeO_4 gave a reddish brown compd., $\text{Se}(\text{C}_6\text{H}_4\text{OH})_2$, sol. in EtOH , Me_2CO and alkali hydroxides, sparingly sol. in Et_2O and insol. in CHCl_3 , C_6H_6 and NH_4OH . It is probably identical with the seleno-

phenol of Michaelis and Kuncell (*Ber.* 30, 2823). In like manner, $\text{PhOCH}_2\text{CO}_2\text{H}$ and H_2SeO_3 gave *diphenoxyacetic acid-selenoxide*, bright yellow, decomp. 210° . The above 2 reactions are represented by the following equations: $2\text{PhOH} + \text{H}_2\text{SeO}_3 = \text{Se}(\text{C}_6\text{H}_4\text{OH})_2 + 2\text{H}_2\text{O} + \text{O}$. $2\text{PhOCH}_2\text{CO}_2\text{H} + \text{H}_2\text{SeO}_3 = \text{SeO}(\text{C}_6\text{H}_4\text{OCH}_2\text{CO}_2\text{H})_2 + 2\text{H}_2\text{O}$.

NAO UYER

Organic derivatives of silicon. XXXVI. Highly complex condensation product of diphenyl- and di-*p*-tolylsilicanediol. Fission of the Si-Ph link. FREDERICK S. KIPPING AND ARTHUR G. MURRAY. Univ. College, Nottingham. *J. Chem. Soc.* 1928, 1427-31; cf. *C. A.* 22, 776.—When 10 g. Ph_2SiCl_2 is dissolved in 200 cc. 10% aq. KOH and the clear liquid concd. on the H_2O bath to about 75 cc., there sep. insol. products; repeated washing with H_2O and extn. with Me_2CO and C_6H_6 finally gives an insol. product A, SiPh_2O , amorphous, decomp. much above 360° , sparingly sol. in molten camphor but freely sol. in boiling PhNH_2 , from which it seps. after 2 hrs., boiling as an amorphous product; in the presence of a little H_2O it is completely hydrolyzed; it is not appreciably changed by boiling with 5% KOH in aq. Me_2CO for several hrs., but when heated with concd. alkali at 150° it is slowly decompd., giving C_6H_6 and a silicate. From the C_6H_6 ext. obtained in purifying A, there seps. B (SiPh_2O), an amorphous product, which begins to sinter at 300° and gradually liquefies at a considerably higher temp.; it is very slowly hydrolyzed by KOH in Me_2CO . (*p*- MeC_6H_4) $_2\text{SiCl}_2$ behaves similarly, the insol. amorphous product, $\text{Si}(\text{C}_7\text{H}_7)_2\text{O}$, shows signs of sintering at 270° but does not completely m. 360° ; it is not appreciably changed by boiling with 5% KOH in Me_2CO ; the C_6H_6 ext. gives a gelatinous solid, $\text{Si}(\text{C}_7\text{H}_7)_2\text{O}$, which sinters at 260° but does not completely m. 360° ; it is only slowly hydrolyzed by KOH- Me_2CO . Ph_2SiO , heated with 20% KOH at 100° under reduced pressure, gives after 3 hrs. 1% C_6H_6 . **XXXVII.** Production of tetrabenzylsilicane, tribenzylsilyl oxide and other products by the action of sodium on dibenzylsilicon dichloride. ALFRED R. STEELE AND F. S. KIPPING. *Ibid* 1431-9.—The action of 2.25 atoms of Na upon 50 g. $(\text{PhCH}_2)_2\text{SiCl}_2$ in 500 cc. PhMe in an atm. of N for 20 hrs., followed by 1-2 g. K for 5 hrs., gives 1 g. of an insol. product, contg. 28-34% Si; this is a gray powder, insol. in all common solvents and does not give H when heated with KOH in EtOH or Me_2CO ; 1 g. $[(\text{PhCH}_2)_2\text{Si}]_2\text{O}$; 4-5 g. $(\text{PhCH}_2)_4\text{Si}$; and, as the principal product, thick oils, which gradually harden to transparent or translucent, brittle masses, consisting of $[(\text{PhCH}_2)_2\text{Si}]_n\text{O}$; the O probably results from Na_2O present in the Na. In some cases the PhMe soln. has a mahogany color at the end of the reaction; this is assumed to be due to the conversion of the $[(\text{PhCH}_2)_2\text{Si}]_n\text{O}$ into Na or K derivs., from which other oxides are subsequently formed. Examples are given of the fission of the SiCH_2Ph linkage.

C. J. WEST

The action of nitric acid on phenol in dilute aqueous solutions. A. V. KARTASHEV. *J. Russ. Phys.-Chem. Soc.* 59, 819-32 (1927).— PhOH heated to $94-6^\circ$ for 4 hrs. with 5 equivs. of 9% HNO_3 yields chiefly 2,4-(O_2N) $_2\text{C}_6\text{H}_3\text{OH}$, besides picric acid and a tarry residue. No reaction occurs on heating with 1 equiv. of 2.8% HNO_3 , while oxidation takes place if the latter is present in excess. Heating to $96-8^\circ$ with an equiv. of 2.8-8 13% HNO_3 yields tar; nitration takes place at $40-50^\circ$ or excess HNO_3 . The temp. at which the reaction starts depends on the concn. of HNO_3 and on the oxidation products of PhOH which act as catalysts. The addn. of HCHO , BzH , or $\text{C}_6\text{H}_{12}\text{O}_6$ similarly lowers the reaction temp. and favors the oxidation of PhOH . K. concludes, the main reaction is oxidation.

BASIL C. SOYENKOFF

The nitration of phenol. A. V. KARTASHEV. *J. Russ. Phys.-Chem. Soc.* 59, 833-45 (1927).—The nitration of PhOH is preceded by oxidation (cf. preceding abstr.). The HNO_2 formed gives nitrosophenols with PhOH which are further oxidized to nitro derivs. Liebermann's test was positive (dark blue to green). The addn. of HNO_2 to a cold mixt. does not lower the temp. of the reaction, and no nitrosophenols are formed; when the mixt. is at 80° , HNO_2 starts the reaction accompanied by the evolution of heat (in the control expt. at 92°). Or the formation of nitrosophenols takes place within certain temp. limits. The addn. of nitrosophenols to the cold PhOH-HNO_2 mixt. lowers the initial reaction temp. by $5-10^\circ$. Nitrosophenols are readily transformed by cold dil. HNO_3 into the mononitro compds. Dinitro derivs. result upon continued heating. Very dil. hot HNO_3 acts as a strong oxidizer, *o*- $\text{O}_2\text{NC}_6\text{H}_4\text{OH}$ is not oxidized by heating on the water bath with 5.5% HNO_3 , 2,4-(O_2N) $_2\text{C}_6\text{H}_3\text{OH}$ being formed instead. The action of HNO_3 on PhOH is oxidation paralleled by the formation of NO compds.

BASIL C. SOYENKOFF

Bromophenols. XXX. Halogenated *o*-anisidines. MORITZ KOHN AND REGINE KRAMER. Wiener Handelsakademie. *Monatsh.* 49, 146-59 (1928); cf. *C. A.* 22, 233.—*p*- $\text{ClC}_6\text{H}_4\text{OH}$ with Me_2SO and 20% KOH gives *p*- $\text{ClC}_6\text{H}_4\text{OMe}$, b. $193-7^\circ$; nitration

gives 4,2-Cl(O₂N)C₆H₃OMe, m. 96°, which is reduced to 4,2-Cl(H₂N)C₆H₃OMe, m. 82°; in AcOH 2 mols. Br give 3,5-dibromo-4-chloro-2-aminoanisole, pale lilac, m. 113°; the constitution was established by the removal of the NH₂ group, giving 4,3,5-ClBr₂C₆H₂OMe, b₇₄₀ 296°, m. 79°, which, on heating with HBr in AcOH, gives 4,3,5-ClBr₂C₆H₂OH, m. 118°, whose Bz deriv., m. 132°. Nitration of 4,3,5-ClBr₂C₆H₂OMe gives the 2,6-di-NO₂ deriv., demethylated by C₆H₅N to the phenol deriv., m. 146-7°. *p*-ClC₆H₄OMe is nitrated to the 2,6-di-NO₂ deriv., m. 64°, which is demethylated by C₆H₅N; the phenol m. 79°. Heating 4,3,5,2-ClBr₂(H₂N)C₆HOMe with Ac₂O and then nitrating gives 4-chloro-3,5-dibromo-2-acetamido-6-nitroanisole, carbonizes at 215°; concd. H₂SO₄ at 100° for 15-20 min. gives the amino compd., S-yellow, m. 82°. 2,4-Cl₂C₆H₃OH with Me₂SO₄ and 20% KOH gives 2,4-Cl₂C₆H₃OMe, b. 222-7°; nitration gives the 6-NO₂ deriv., m. 42°, which gives 2,4,6-Cl₂(O₂N)C₆H₂OH, m. 124°, with HBr in AcOH. Reduction gives the 6-NH₂ deriv., whose Ac deriv., m. 72°. Nitration gives 1-methoxy-2,4-dichloro-3,5-dinitro-6-acetamidobenzene, m. 219°; the amino compd., deep yellow, m. 135°. 2,4,6-Cl₃(H₂N)C₆H₂OMe with 2 mols. HBr gives the 3,5-di-Br deriv., m. 83°. XXXI. 3,4,5-Trichlorophenol. *Ibid* 161-8—4,2-Cl(H₂N)C₆H₃OMe with 4 mols. Cl gives a colored 3,4,5-Cl₃ deriv., which was not analyzed but transformed, through the diazo reaction, into 3,4,5-trichloroanisole, b. 256-61°, m. 63°. HBr in AcOH gives 3,4,5-trichlorophenol, b₇₄₆ 271-7°, m. 91°; Bz deriv., m. 120°; 2,6-di-Br deriv., m. 180°, d 2.554; crystallographic data are given for this and for the 3,5-Cl₂, 3-Cl and 4-Cl derivs. HNO₃ gives 2,6-dibromo-3,5-dichloroquinone, yellow, undecompd. at 240°. 2,6-Dinitro-3,4,5-trichloroanisole, m. 95-6°. XXXII. Preparation of 2,6-dibromo-*m*-xyloquinone from symmetrical xylenol. M. KOHN AND M. K. FELDMANN. *Ibid* 169-72.—2,4,6,3,5-Br₂Me₂C₆OH, whose Me ether, m. 116°, is oxidized by fuming HNO₃ to 2,6-dibromo-*m*-xyloquinone, yellow, m. 176° (crystallographic data are given); it is unstable in the air; SO₂ reduces it to 1,3-dimethyl-4,6-dibromo-2,5-dihydroxybenzene, m. 180°; Bz deriv., m. 253°; di-Me ether, b₇₄₀ 309-11°, m. 116°. XXXIII. Chloro- and bromopyrogallol ethers. M. KOHN AND ELISABETH GUREWITSCH. *Ibid* 173-86.—1,2,3,5-(MeO)₂C₆H₃NO₂ (5 g.) and 28 cc. Br give the 4,6-di-Br deriv., m. 112-4° (crystallographic data are given), thus confirming the structure assigned by Kohn and Grün (C. A. 20, 1609). Heating 1 mol 1,3,5-C₆H₃(OMe)₃ with 1 mol PCl₅ gives the 4-Cl deriv., b₇₄₈ 252-6°; nitration gives the 5,6-di-NO₂ deriv. (I), m. 116-8°; the 5,6-di-Br deriv., m. 57-8°. 1,2,3,5-(MeO)₂C₆H₃NO₂ and about 6 mols. Cl give the 4-Cl deriv., m. 77-8°. Nitration of 1,2,3,4,5-(MeO)₂ClC₆HNO₂ gives I. Chlorination of 1,2,3,5-(MeO)₂C₆H₃NO₂ gives the 4,6-di-Cl deriv., m. 103-4°. 1,3,2-(MeO)₂C₆H₃OH and 1 mol. SO₂Cl₂ give the 4-Cl deriv., b₁₈ 175°, b₇₅₄ 270.5°; Me₂SO₄ gives 1,2,3-trimethoxy-4-chlorobenzene, b₇₁₉ 250.60°; which is nitrated with fuming HNO₃ to I. With somewhat more than 3 mols. Cl, 1,3,2-(MeO)₂C₆H₃OH yields the 4,5-di-Cl deriv., m. 103-4° (Bz deriv., m. 122-3°); the 6-Br deriv., m. 117-8°. Oxidation of the tribromo- or trichloropyrogallol di-Me ether with CrO₃ gives the 2,6-dimethoxy 3,5-dibromo- or dichloroquinone, m. 175° and 159°, resp.

C. J. WEST
Ketones of carvacrol. K. W. ROSENMUND AND CHIENCHI WHA. *Arch. Pharm.* 266, 407-11 (1928).—The following ketones and derivs. were prepd. and characterized. *carvacrol* Me ketone, C₁₂H₁₄O₂ (1-Me, 2-OH, 4-Pr, 5-Ac), m. 120° (Me ether, C₁₃H₁₆O₂, b₁₈ 164°); Et ketone, m. 110°, b₁₅ 201° (ketoxime, m. 145°); Pr ketone, m. 90°, b₁₆ 200° (ketoxime, m. 120°); carvacrol Et and Pr ketones gave on reduction with HCl and Zn wool treated with 5% HgCl₂ the corresponding propylcarvacrol, C₁₃H₂₀O, b_{14.5} 150°, and butylcarvacrol, b₁₂ 158°; condensation product of the Me ketone with BzH, C₁₉H₂₂O₃, m. 158°; condensation product of the ketonic Me ether with BzH, C₂₀H₂₄O₃, m. 72°; with diethyl ketomalonate, K salt, C₁₆H₁₈O₇K₂; free acid, m. 96° (Et ester, b_{6.5} 190°); Et ω -methoxy- γ -keto- α -hydroxybutyrate, C₁₇H₂₄O₆, b_{6.36} 180-4°. W. O. E.

Action of oxalyl chloride upon resorcinol. JOSIP MIKŠIĆ. *Univ. Zagreb J. prakt. Chem.* 119, 218-30 (1928).—*m*-C₆H₄(OH)₂ (50 g.) in 250 cc. moist Et₂O, treated with cooling with 7 g. Na wire and 20 g. (COCl)₂, heated several hrs. on the H₂O bath, again treated with 20 g. (COCl)₂, boiled 2 days and again treated with 20 g. (COCl)₂

$$\begin{array}{c} \text{HOC}_6\text{H}_3 \\ \diagup \quad \diagdown \\ \text{O} \quad \text{CHCH}(\text{OH})\text{C}_6\text{H}_3(\text{OH})_2 \quad (2,4), \text{ yellow, m. } 155-60^\circ \\ \diagdown \quad \diagup \\ \text{HOC}_6\text{H}_3 \end{array}$$

(decompn.); the alk. solns. have a pale green fluorescence; concd. H₂SO₄ gives a deep blue soln.; from MeOH it crystallizes with 1 mol. of solvent; melting with solid KOH gives β -resorcylic acid; distn. with Zn gives xanthone and *m*-C₆H₄(OH)₂; penta-Ac deriv., m. 197°. The formation of this compd. is explained by the intermediate formation of OHCCOCl, which reacts to form a ketone, which in turn is reduced by the Na.

When 33 g. $m\text{-C}_6\text{H}_4(\text{OH})_2$ is treated, without cooling, with 20 g. $(\text{COCl})_2$ and then with 12 g. K and the mixt. warmed 2 days, the Et_2O removed and the product taken up in Me_2CO , H_2O ppts. 20 g. *resjankin* (I), $\text{C}_{14}\text{H}_{18}\text{O}_{10}$, pale rose, sol. in H_2O (green fluorescence), from which it is pptd. by KCl; KOH gives a violet color; dil. solns. change to an intense red. The alk. soln. quickly decolorizes KMnO_4 . The K salt forms long, violet needles. Melting with NaOH gives β -resorcylic acid and $m\text{-C}_6\text{H}_4(\text{OH})_2$; distn. with Zn dust gives xanthone and $m\text{-C}_6\text{H}_4(\text{OH})_2$. *Tetra-Ac deriv.*, m. $170\text{--}2^\circ$. The aq. mother liquor from I slowly deposits *resperin* (II), $\text{C}_{22}\text{H}_{28}\text{O}_{11}$, whose *Ac deriv.* m. $159\text{--}9.5^\circ$. The NaOH melt gives dihydroxyxanthone and β -resorcylic acid. The absorption spectra of I and II are given

C. J. WEST

Glycol from methylethylacetaldehyde and benzaldehyde. ADOLF FRANKE AND ROSA STERN Univ. Wien. *Monatsh.* 49, 21–6(1928)— MeEtCHCHO and BzH , condensed by a slight excess of alk. KOH, give *1-phenyl-2-methyl-2-ethylpropane-1,3-diol* (I), b_{17} $188\text{--}90^\circ$, does not solidify at -19° ; *diacetate*, b_{20} $189\text{--}91^\circ$, in 2 expts., there resulted, not I, but its benzal deriv., $\text{C}_{19}\text{H}_{22}\text{O}_2$, b_{18} $214\text{--}5^\circ$, m. $80\text{--}1^\circ$, which also results from I and BzH with concd. HCl. Oxidation of I with KMnO_4 gives MeEtCHBz . Distn. of I with 14% H_2SO_4 gives the *hydrocarbon*, $\text{C}_{10}\text{H}_{14}$, b. $205\text{--}6^\circ$; this is probably PhCH.CMeEt , whose *di-Br addn. compd.* m. 57° ; the 2nd product is the *compd.*, $\text{C}_{13}\text{H}_{18}\text{O}_2$, b_{13} $156.5\text{--}7^\circ$, which is also obtained from I, HCHO and HCl; the pure *compd.* b_{12} 150° ; it is therefore a *formal* of I.

C. J. WEST

Benzal formation in glycols. ADOLF FRANKE AND JEMMERICH GIGERL. Univ. Vienna. *Monatsh.* 49, 8–20(1928)— $\text{Me}_2\text{C}(\text{CH}_2\text{OH})_2$ and a little more than 1 mol. BzH , treated with cooling with dry HCl for about 1 hr., give 68% of the benzal of *2,2-dimethylpropane-1,3-diol*, b_{10} $123\text{--}4^\circ$, m. 35° , this also results by heating the components with 5 parts 1% EtOH-HCl 1 hr. (65% yield). *Butane-1,3-diol* gives 55.5% of a benzal, b_9 117.5° . *1-Phenyl-2,2-dimethylpropane 1,3-diol* gives 50% of the benzal, m. 98° . *2-Methylpentane-2,4-diol* yields a benzal, b_9 124° . *2,4-Dimethylpentane-2,4-diol* gives 20% of a benzal, b_{16} $127\text{--}8^\circ$, m. 42° . Definite products could not be obtained from pentane-1,4-diol, camphor glycol or decane-1,10-diol, the glycol being obtained unchanged in the case of the last *compd.*

C. J. WEST

Mobile anion tautomerism. II. A complementary study of the mechanism of anionotropic change, with special reference to the fate of the mobile anion. HAROLD BURTON Univ. of Leeds. *J. Chem. Soc.* 1928, 1650–7; cf. *C. A.* 22, 2556.—The study of the mechanism of anionotropic change divides itself into 2 portions: The behavior of the electrons in the electromeric cation under different conditions of structure (see part I) and the behavior of the eliminated anion under different conditions of catalysis, it is now shown that the mobile group undergoes ionic disson. promoted by some mol. property of the solvent closely related to its dielec. const. It is suggested that the anion combines electrostatically with the catalyst by means of the preëxisting, plus the induced, dipolar field of the latter. $\text{CH}_2\text{:CHCH}(\text{OCOC}_6\text{H}_4\text{NO}_2)\text{Ph}$ was converted into $\text{PhCH:CHCH}_2\text{OCOC}_6\text{H}_4\text{NO}_2$ by boiling with Ac_2O for 6 hrs., by heating in PhCN at 140° for 6 hrs. and by heating in PhCl or $p\text{-C}_6\text{H}_4\text{Me}_2$ for 72 hrs., but not in chloral. Boiling a mixt. of $\text{CH}_2\text{:CHCH}(\text{OH})\text{Ph}$ with $p\text{-O}_2\text{NC}_6\text{H}_4\text{COCl}$, AcONa and Ac_2O gives a mixt. of $\text{PhCH:CHCH}_2\text{OCOC}_6\text{H}_4\text{NO}_2$ and $\text{PhCH:CHCH}_2\text{OAc}$. The latter is unchanged by boiling with $p\text{-O}_2\text{NC}_6\text{H}_4\text{COCl}$ and AcONa . The acetate also results from $\text{PhCH:CHCH}(\text{OCOC}_6\text{H}_4\text{NO}_2)\text{Ph}$ by heating with Ac_2O and Me_4NOAc for 6 hrs. $\alpha\text{-}p\text{-Chlorophenylallyl alc.}$, b_{10} $122\text{--}3^\circ$, from $p\text{-ClC}_6\text{H}_4\text{MgI}$ and $\text{CH}_2\text{:CHCHO}$; $p\text{-nitrobenzoate}$, m. 170° ; boiling the alc. with Ac_2O for 6 hrs. and hydrolysis gives $p\text{-chlorocinnamyl alc.}$, m. $57\text{--}8^\circ$; $p\text{-nitrobenzoate}$, m. $130\text{--}1^\circ$. Either alc. with HBr gives $p\text{-chlorocinnamyl bromide}$, m. $62\text{--}3^\circ$. $\alpha\text{-}m\text{-Tolylallyl alc.}$, b_{11} $115\text{--}7^\circ$; $p\text{-nitrobenzoate}$, m. 53° ; AcO and hydrolysis give $\alpha\text{-3-methylcinnamyl alc.}$, b_{11} $137\text{--}40^\circ$; $p\text{-nitrobenzoate}$, m. $63\text{--}4^\circ$; the bromide is a straw-colored oil, b_{11} $138\text{--}40^\circ$, which slowly decomps. into a black, viscous mass.

C. J. WEST

Laws of aromatic substitution. VIII. BERNHARD FLÜRSCHHEIM AND ERIC L. HOLMES. *J. Chem. Soc.* 1928, 1607–16; cf. *C. A.* 22, 1962.—*Tri-Et phenylmethanetricarboxylate*, b_{14} $154\text{--}5^\circ$, results from $\text{CPhNa}(\text{CO}_2\text{Et})_2$ and ClCO_2Et ; $\alpha\text{-NO}_2$ deriv., m. $83\text{--}4^\circ$. *Di-Et phenylchloromalonate*, b_2 $143\text{--}4^\circ$. On nitration, the following % of *m*-isomer are obtained: PhCH_2Cl , 11.6; $\text{PhCH}_2\text{CO}_2\text{Et}$, 12.1; PhCHCl_2 , 33; $\text{PhCH:ClCO}_2\text{Et}$, 14.2; $\text{PhCH}(\text{CO}_2\text{Et})_2$, 25.4; PhCCl_3 , 48.4; $\text{PhCCl}_2\text{CO}_2\text{Et}$, 32.7; $\text{PhCCl}(\text{CO}_2\text{Et})_2$, 52.9; $\text{PhC}(\text{CO}_2\text{Et})_3$, 56.5; PhCH_2Br , 6.6; $\text{PhCBr}(\text{CO}_2\text{Et})_2$, 39.4. The results with $\text{PhC}(\text{CO}_2\text{Et})_3$ constitute the first case of preponderating *m*-nitration in the exclusive presence, at the $\alpha\text{-C}$ atom, of such substituents as would be *m*-directing if directly attached to the nucleus. Where the quant. factor is not very pronounced—*e. g.*, at an $\alpha\text{-C}$ atom which neither forms part of an ethylenic or acetylenic group nor is

linked to substituents possessing a much higher or lower affinity demand than H— and where at the same time the polar factor is very pronounced—e. g., in the case of an α -C atom directly linked to an atom charged through electrolytic dissoen. or to several substituents of distinct and similar polarity—there the quant. factor may be overborne by the polar effect. But even in such extreme cases the quant. factor can be distinctly traced. The electrolytic dissoen. const. of aromatic acids and bases, substituted in the *m*- or *p*-positions by Cl on the one hand, by CO_2Et on the other, show that the polar effect transmitted from these positions is greater with CO_2Et than with Cl. The *m*-directive effect, however, as evidenced by the above results, is less for CO_2Et than for Cl.

Phenylstearic acid. CLARA MARIE DE MILT. *Abstracts of Theses, Univ. Chicago, Science Series* 4, 123-8(1925-6) (publ. May, 1928).—A phenylstearic acid, which is probably 10-phenylstearic acid (about 40% from 200 g. oleic acid and 400 g. PhH , with 100 g. AlCl_3 as a catalyzer) is a viscous, pale yellow, almost odorless liquid, b_d 250°, n_D^{25} 1.4905. The *K* and *Na* salts are soaps. *Pb* salt, m. about 86°, creamy-white, waxy, sol. in Et_2O , CHCl_3 and ligroin. *Ag* salt, white. *Me ester*, pale yellow oil, b_d 228°, n_D^{25} 1.4840. The *amide* is liquid. *Anilide*, faintly yellow liquid, b_d 282°. Phenylstearic acid was easily nitrated, but no definite product of reaction could be isolated. G. J. WEST

Isomeric 2-amino- α -arylcinnamic acids. JOHN M. GULLAND AND CYRIL J. VIRDEN. Dyson Perrins Lab., Oxford. *J. Chem. Soc.* 1928, 1478-86.—2,5-(MeO) $_2$ $\text{C}_6\text{H}_3\text{CHO}$, $\text{BzNHCH}_2\text{CO}_2\text{H}$, AcONa and Ac_2O give 75% of 5-*keto*-2-phenyl-4-[2',5'-dimethoxybenzylidene]-4,5-dihydrooxazole, orange, m. 170-2°; boiling a short time with EtOH - HCl gives α -benzylamino-2,5-dimethoxycinnamic acid, m. 195-6°; hydrolysis with 10% NaOH gives 76% of 2,5-dimethoxyphenylpyruvic acid, cream-colored, m. 166-70° (decompn.); with o - $\text{C}_6\text{H}_4(\text{NH}_2)_2$ this gives 3-hydroxy-2',5'-dimethoxy-2-benzylquin-oxaline, m. 179-80°, which crystallizes with 0.5 EtOH . Oxidation gives 2,5-(MeO) $_2$ - $\text{C}_6\text{H}_3\text{CH}_2\text{CO}_2\text{H}$, which condenses with 2-nitroveratraldehyde to give *trans*-2-nitro-3,4,2',5'-tetramethoxy- α -phenylcinnamic acid (I), bright yellow, m. 204-5°, and a small quantity of 2,3,4- $\text{O}_2\text{N}(\text{MeO})_2\text{C}_6\text{H}_3\text{CH}(\text{CHCO}_2\text{H})$, m. 229°; the quantity of the latter increases rapidly with rise in temp. Reduction of I with NH_4OH and FeSO_4 gives a mixt. of the *trans*-2-amino acids, A (II) and B (III); II, colorless, m. 219°, crystallizes with 0.5 H_2O from EtOH ; III, from the EtOH mother liquor, yellow, m. 167°; III is unimol. in camphor while II is bimol.; in $(\text{PhN})_2$, both were associated, but at comparable concns., the values for the mol. wt. of II were approx. twice those of III; in AcOH both appear to be unimol. but the values for II were consistently low. III in EtOH , exposed to ultra-violet light for several days, or heated with Ac_2O - H_2SO_4 for 30 min., gives 7,8,2',5'-tetramethoxy-3-phenylcarbostyryl (IV), m. 189°. IV also results from II and Ac_2O - H_2SO_4 . III is transformed into II in $(\text{PhN})_2$, as shown by the change in f. p. The addn. of AcONa or AcOH to an acid or alk. soln. of II ppts. III; the addn. of AcOH to the NH_4OH soln. of III ppts. II. The action of ultra-violet light on the Na salt of I gives a small yield of the *cis*-acid, pale yellow, m. 186°; alk. reduction gives the *cis*- NH_2 acid, which passes into IV on acidification. The diazo soln. from II or III, heated at 60°, gives 3,4,5,8-tetramethoxyphenanthrene 9-carboxylic acid, m. 190-8°; heating at 240° for 40 hrs. gives 3,4,5,8-tetramethoxyphenanthrene, light brown, m. 118-20° (*picrate*, dark chocolate, m. 158°). From the data now available it is not possible to decide whether the H_2O of crystn. of II is essential for the production of the bimol. form, or whether II is composed intrinsically of 2 mols. of the III type.

C. J. WEST

Action of phosphorus pentachloride on homophthalic acid. WM. DAVIES AND HARRY G. POOLE. Univ. of Melbourne. *J. Chem. Soc.* 1928, 1616-20.—Homophthalic anhydride in dil. EtOH , treated with 0.1 *N* KOH , the cold yellow soln. made faintly acid with dil. H_2SO_4 and FeCl_3 added, gives a bluish violet color, which lasts for a considerable time, showing the existence of the enolic form of the anhydride. With PCl_5 in POCl_3 a tarry mass results, but when 20 g. of the acid is heated with 50 g. PCl_5 in 50 g. POCl_3 3 hrs. at 140-50° there results 5 g. 3-chloroisocoumarin, lachrymatory, b_d 150°, m. 98.5-9°, shows a strong blue fluorescence in org. solvents and is stable toward neutral or acid hydrolytic agents; it reacts slowly with NH_3 in C_6H_6 , giving a small quantity of o - $\text{HO}_2\text{CC}_6\text{H}_4\text{CH}_2\text{CN}$, m. 126°; aq. NaOH gives the original acid; PhNH_2 in C_6H_6 gives homophthalanilide, m. 231.5°. Heating 54 g. acid with 250 g. PCl_5 in 100 g. POCl_3 8 hrs. at 140-50°, gives 12 g. 3,3,4,4-tetrachloro-3,4-dihydroisocoumarin, m. 122°; PhNH_2 in C_6H_6 gives an *anilide*, m. 225°. Further action of PCl_5 at high temps. gives an oily mixt., whose hydrolysis product is phthalonic acid, identified by conversion into a *compd.*, m. 239°, with p - $\text{O}_2\text{NC}_6\text{H}_4\text{NHNH}_2$.

C. J. WEST

The basicity of nitrophenoxymalonic acids. I. S. TELESTOV AND N. N. ANDRONI-

KOVA. *J. Russ. Phys.-Chem. Soc.* 59, 1199–204 (1927).—Titration with NaOH and cond. measurements of the salts show *o*-, *m*- and *p*-C(OC₆H₄NO₂)₂(CO₂H)₂ to be dibasic. (*p*-O₂NC₆H₄O)₂C(CO₂Na)₂ prep'd. both by sapon. of the Me ester and by neutralization of the acid m. 110° and showed the same cond. in H₂O. *p*-O₂NC₆H₄OCH(CO₂H)₂ is a weaker dibasic acid than the disubstituted ones since the cond. of its Na salt changes less on diln.

BASIL C. SOYENKOFF

Constituents of *Zanthoxylum setosum* Hemsl. T. ARAKI and Y. MIYASHITA. Central Expt. Sta. (Formosa). *J. Pharm. Soc. Japan* 48, 437–46 (1928).—From an alc. ext. of the leaves of *Zanthoxylum setosum*, an oil with a characteristic odor and 2 cryst. substances were isolated. One of the latter had the compn. C₁₄H₁₄O₆ and m. 104°, while the other (I) had the compn. C₁₁H₁₀O₄. I, m. 147–8°, shows bluish violet fluorescence in alc. It has 2 MeO groups and by catalytic reduction, with Pt black, it gives an aromatic substance C₁₁H₁₀O₄. It forms an oxonium salt with concd. H₂SO₄ or HCl. The above facts and also the color reactions with acids show a close resemblance between I and the limettin (5,7-dimethoxycoumarin) (II) of Tilden and Beck (*J. Chem. Soc.* 57, 323 (1890)). II and Br in either C₆H₆ or AcOH gave C₁₁H₉O₄Br₂, bright yellow, m. 257°, while I and Br in AcOH gave C₁₁H₁₀O₄Br₂, white, m. 235°. I and Br in C₆H₆, on the other hand, gave C₁₁H₉O₄Br, m. 176°. From this fact, it appears that I is probably an isomer of II. Boiling of I with 30% KOH for 8 hrs. gave dimethoxy-*o*-coumaric acid (III), C₁₁H₁₂O₆, yellow, m. 197–8°. Ac deriv., m. 210–11°. Heating of III with POCl₃ for 8 hrs., resulted in a ring closure and gave a yellow compd., m. 145–6°, which was found to be identical with I.

NAO UYEI

A new synthesis of 3,4,5-trimethoxy-*o*-phthalic acid. K. FEIST and G. L. DSCHU. Univ. Göttingen. *Festschrift A. Tschirch* 1926, 23–9; *Chem. Zentr.* 1927, II, 58.—3,4,5-Trimethoxy-*o*-phthalic acid (I) was prep'd. from 3,4,5-trimethoxygallic acid (II) in 2 different ways. (1) Gallic acid, Me₂SO, and NaOH form 3,4,5-(MeO)₃C₆H₂CO₂H and the latter and CCl₃CHO·H₂O form 3,4,5-trimethoxytrichlorophthalide, m. 71–2°. The latter refluxed in MeOH with NaOH, dild. with water, the MeOH expelled, supersatd. with HCl, extd. with Et₂O and evapd. yields 3,4,5-trimethoxyphthalidecarboxylic acid (III), m. 147–8°. The residue from the Et₂O extn. on treatment with CH₃N₃ (IV) yields the Me ester of III, m. 121°. III heated in *vacuo* yields 3,4,5-trimethoxyphthalide, m. 134–5°. The latter dissolved in hot NaOH, cooled and treated with KMnO₄, filtered, treated with SO₂, evapd., acidified with HCl, and extd. with Et₂O, yields I, m. 163°. 3,4,5-Trimethoxyphthalic anhydride, m. 143°. Di-Me ester of I, m. 64–5°. (2) II in CHCl₃ heated with Br in CHCl₃ in presence of powd. Fe until HBr is no longer evolved, the CHCl₃ distd. off, dild. with water, boiled and filtered hot, yields bromo-trimethoxygallic acid (V), m. 148°. From the mother liquor is obtained an addn. compd. of V and II. IV added to alc. V yields the Me ester of V, m. 33°. This ester boiled with Mg chips in presence of I forms 1-mono-Me 3,4,5-trimethoxy-*o*-phthalate, m. 138–41°. Treatment with IV forms its di-Me ester.

C. C. DAVIS

Separation of α - and β -santalol. T. TSUKAMOTO and E. ICHIBASHI. Tokyo Imp. Univ. *J. Pharm. Soc. Japan* 48, 416–22.—A mixt. of the oil of sandalwood in Et₂O and aq. Hg(OAc)₂ was boiled for several days. The Hg compd. of β -santalol was recovered from the Et₂O or aq. layer by addn. of Na₂CO₃ or NaCl, purified and decompd. with H₂S to obtain β -santalol (I). From the Et₂O layer, after removal of I, α -santalol was recovered by decompn. of its Hg compd. by H₂S.

NAO UYEI

Menthol. I. R. SPINNER. Univ. of Berlin. *Riechstoffindustrie* 1926, 160–2; *Chem. Zentr.* 1926, II, 3081.—Methods for the prepn. of menthol and its properties are described.

C. C. DAVIS

Optical activity and the polarity of substituent groups. IX. Menthyl esters of methoxynaphthoic and of diphenyl-2-carboxylic acids. EGON BRETSCHER, H. GORDON RULE and JOHN SPENCE. Univ. of Edinburgh. *J. Chem. Soc.* 1928, 1493–504; cf. C. A. 22, 3157.—The influence of the typically *o*,*p*-directive MeO group on the rotatory powers of the menthyl naphthoates has been examd. and found similar to that exerted in the case of menthyl benzoate. In any position adjacent to the carboxylic complex the substituent depresses the rotatory powers of the 1- and 2-naphthoates. In menthyl 2-methoxy-1-naphthoate the combined effect of the 2 *o*,*p*-directive groups in the 2- and 6-positions actually reverses the sign of rotation, giving a *d*-rotatory ester. In the 4-MeO deriv. the *p*-substituent raises the rotation but in the 5-position it has little or no effect. A MeO group in the *peri*-position also produces a marked diminution in rotatory power, thus indicating that the peculiar *o*-influence is transmitted through space and not through the chain of atoms. A Ph group in the 2-position in menthyl benzoate leads to the diminished rotation characteristic of *o*,*p*-directive substituents. A 2-MeOC₆H₄ group in this position raises the rotation. The relative magnitudes of

the rotatory powers of optically active esters of BzOH , $1\text{-C}_{10}\text{H}_7\text{CO}_2\text{H}$ and $2\text{-C}_{10}\text{H}_7\text{CO}_2\text{H}$ may be correlated with the known influence of *o*-, *m*- and *p*-substituents on the benzoic esters. *Menthyl 2-methoxy-1-naphthoate*, from the acid chloride, menthol and $\text{C}_6\text{H}_5\text{N}$ in C_6H_6 , m. $122\text{--}3^\circ$. *4-MeO deriv.*, m. $114\text{--}5^\circ$. *8-MeO deriv.*, m. $98\text{--}6.5^\circ$ (from the acid, m. $162\text{--}3^\circ$, whose *Me ester*, m. $51\text{--}2^\circ$). *5-MeO deriv.*, m. $90\text{--}3^\circ$. *Menthyl diphenyl-2-carboxylate*, b_{10} 175° ; *2'-MeO deriv.*, b_{10} $171\text{--}3^\circ$. Values are given for the rotation of these compds. in various solvents for the wave lengths 6708, 5893, 5461 and 4358. C. J. WEST

Constituents of camphorol. M. ISHIDATE. Tokyo Imp. Univ. *J. Pharm. Soc. Japan* 48, 410-5 (1928).—Recently Asahina and I. (*C. A.* 22, 2161) showed that the *d*-camphorol (I) of Schmiedeberg and Meyer is a mixt. of 3-hydroxycamphor (II) and 5-hydroxycamphor (III). This conclusion was reached from the study of their oxidation products. By repeated fractional crystn. from ligroin (IV), I has now been sepd. into II and III. II is easily sol. in IV and m. $193\text{--}5^\circ$. *Semicarbazone*, m. $183\text{--}4^\circ$, $[\alpha]_D^{25}$ 15.2° . By CrO_3 oxidation, it gave camphorquinone quant., and with Na-Hg it gave *d*-camphor. It is identical with the α -hydroxycamphor of Bredt and Ahrens (*C. A.* 20, 2157). III gave a *mono-Ac deriv.*, b_{27} $159\text{--}60^\circ$, and *semicarbazone*, m. $233\text{--}5^\circ$. III, $\text{K}_2\text{Cr}_2\text{O}_7$ and AcOH gave *p*-diketocamphane, while with Na-Hg it gave *d*-camphor and *p*-dihydroxycamphane. NAO UYET

The camphor series. X. Anomalous changes of the boiling point of isobornyl acetate. YASUJI FUJITA. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 1-48 (1928); (English Ed.) 1, 1-3.—F. observed that isobornyl acetate prepd. from camphene by the Bertram-Walbaum method b_{11} $134\text{--}64^\circ$ during the 1st distn., b_{18} $80\text{--}100^\circ$ during the 2nd distillation, b_{20} $110\text{--}20^\circ$ the 3rd time and b_{18} $165\text{--}6^\circ$ the 4th time. The 5th and following runs gave b_{20} $113\text{--}4^\circ$, which is also observed with samples prepd. with any other than the B.-W. method. Despite the inconsistency of the b. p., the other phys. properties never vary. When O_2 is passed through a neutral Me_2CO soln. of a sample, b_{20} $113\text{--}4^\circ$, the b. p. is raised to b_{10} 154° ; the reverse action is observed by treating the latter with alc. By drastic drying, the b. p. can be lowered from b_{18} $106\text{--}7^\circ$ to b_{18} 104° . Other consts. of this dry form are: $[\alpha]_D^{21}$ 1.7° , d_4^{30} 0.9739, d_4^{20} 0.9991, n_D^{30} 1.4538, MR_D 55.00. F. believes that the variations are due to a change in the mol. state of the liquid isobornyl acetate. The vapor pressure and the latent heat of vaporization prove that the sample b_{18} 104° is "abnormal" according to Trouton's rule and Nernst's formula. The mol. complexity of this acetate is less than 1, with every method of measurement. The sample b_{18} $165\text{--}6^\circ$ gives a "normal" value by Longinescu's method. F. discussed the anomalous changes of the b. p. and, in analogy with the azeotropic mixts., he conceives that an ordinary liquid consists of a mixt. of mols. having different degrees of assocn., so that the change in the b. p. takes place according to the change in the proportion of these ingredients. He further discusses the general phenomena of chem. substances which show always a const. b. p., the relation between the proportion of the different ingredients to the b. p. and then the true cause of the changes in the b. p. XI. The separation and identification of borneol and isoborneol. TETSUSAKU IKEDA AND YASUJI FUJITA. *Ibid* 257-68.—Pure borneol can be isolated as follows: treat with $\text{C}_6\text{H}_4(\text{CO})_2\text{O}$; ext. with petroleum ether in which the phthalic acid ester is insol.; dissolve the insol. part in NaOH; steam distil. This method is suitable to sep. borneol from isoborneol and is better than the ZnCl_2 or any other method. For identification borneol or isoborneol are usually treated with HNO_3 (d. 1.4), the former yielding camphor and the latter a liquid substance. If the acid contains NO_2 camphor will be obtained from isoborneol also. The optimum exptl. conditions are recorded for each reaction. XII. Anomalous phenomena observed in the acetylation of borneol. TETSUSAKU IKEDA. *Ibid* 269-97.—When bornyl acetate is prepd. with glacial AcOH and H_2SO_4 and distd., the b. p. changes for each redistn., arriving finally at a stable state, seemingly after passing through 2 intermediary states. The other phys. properties do not vary. Bornyl acetate prepd. by any other method shows a constant b. p. The b. p. change is not due to an isomerization. The mol. complexity of the acetate is far less than 1. A. L. HENNE

Camphor group. VIII. Y. MURAYAMA, K. OHTSUKA AND S. TANAKA. *J. Pharm. Soc. Japan* 48, 429-31 (1928); cf. *C. A.* 22, 955.—Contrary to the statement of Minguin, Bredt, Wieland and others, the authors found that isoborneol ester can best be converted into *p*-ketoborneol ester (II) through its trichloroacetic ester (I) by oxidation with $\text{CrO}_3\text{-AcOH}$. Thus, 100 g. of I, 375 g. AcOH and 210 g. CrO_3 gave about 73 g. crude trichloroacetate of II, which on sapon. gave II (m. $240\text{--}2^\circ$), identical with the product obtained from borneol. IX. A new oxidation product of menthol. Y. MURAYAMA AND

S. TANAKA. Tokyo Imp. Hyg. Lab. *Ibid* 432-7.—Oxidation of menthyl acetate with CrO_3 in AcOH gave an oil, probably with a group OC , whose semicarbazone (I), m. $189-90^\circ$ and has the compn. $\text{C}_{13}\text{H}_{21}\text{N}_3\text{O}_3$. Warming of I with EtOH-KOH resulted in the sapon. of the Ac group and gave a compd. (II), $\text{C}_{10}\text{H}_{15}\text{N}_3\text{O}_3$, m. 190° . Heating of II with 30% HCl liberated semicarbazide and gave an oil (III) with a PhCH:CHCHO -like odor. As judged from the analysis of II, it probably has the structure $\text{AcCH}_2\text{CH}(\text{OH})\text{C}(\text{CH}_3)\text{CHMe}_2$. In like manner, the oxidation of menthyl chloride or benzoate with CrO_3 gave the product whose semicarbazones m. $204-5^\circ$ and 212° , resp. These probably have structures similar to III. NAO UYER

Preparation and constitution of some fluorene thioureas. LUIS GUGLIAMELLI, ARMANDO NOVELLI, CELESTINO RUIZ and CAMILO ANASIASI. *Anales asoc. quim. Argentina* 15, 337-62 (1927).—Thioureas of 1,2- and 2,7-fluorenediamines are of interest because they explain a new configuration of the mol. similar to some Ph_2 derivs. Some fluorene derivs. can be better adapted to this isomerism than by applying the Kauler theory (C. A. 1, 2691), which Cain assumed for Ph_2 . Elimination of free rotation of the C_6H_5 nucleus is singular and not encountered in any other compd. of C chemistry. Buttler and Adams (C. A. 19, 3267) studied this. Thioureas of 1,2- and 2,7-nitroamino- and diaminofluorenes, hitherto unobtained, were prepd. by the original Rathke method (Ber. 5, 799), since not even traces were obtained by the previous CS_2 method. Reasoning from analogies it is assumed that both 1,2- and 2,7-diaminofluorene react in the same way in the presence of *o*-quinone, aldehydes (glyoxal), HCO_2H and AcOH acids, dibenzyl, etc., forming the resp. quinoxalines and imidazoles. E. M. SYMMES

Constitution of phenolphthalein. I. Preparation of some compounds of the phthalein type. HAKON LUND. Univ. of Copenhagen. *J. Chem. Soc.* 1928, 1569-75.—1,3,5- $\text{C}_6\text{H}_3(\text{OMe})_3$ (I) and *p*- $\text{HO}_2\text{CC}_6\text{H}_4\text{CHO}$ with HCl in abs. EtOH give 80% of 2',4',6',2'',4'',6''-hexamethoxytriphenylmethane-4-carboxylic acid, m. $258-60^\circ$; oxidation in AcOH with Ph(OAc) gives 4-carboxy-2',4',6',2'',4'',6''-hexamethoxytriphenylcarbinyl acetate, violet-black powder with bronze luster, giving a very intense violet color in all solvents but Et_2O ; the colorless Et_2O soln. becomes colored when shaken with H_2O ; perchlorate, violet leaflets with an intense metallic luster, decomps. violently when heated. I and *o*- $\text{HO}_2\text{CC}_6\text{H}_4\text{CHO}$ give 2',4',6'-trimethoxyphenylphthalide, m. 200° . I and *o*- $\text{C}_6\text{H}_4(\text{COCl})_2$ with ZnCl_2 give phloroglucinolphthalein hexa-Me ether, m. $175-8^\circ$; HCl gives a violet soln. With concd. HCl , followed by hydrolysis with aq. KOH , it gives 2',4',6'-trimethoxybenzoyl-*o*-benzoic acid, m. $184-5^\circ$. 2',4'-Dimethoxybenzoyl-*o*-benzoic acid and *m*- $\text{C}_6\text{H}_4(\text{OMe})_2$ with concd. H_2SO_4 in Et_2O give resorcinolphthalein tetra-Me ether, m. 153° ; 20% HCl gives a reddish violet color; the 2',4'-di-Me ether, m. 220° . Phloroglucinolphthalein 2',4',6'-tri-Me ether, m. 200° . All m. ps. are cor. C. J. W.

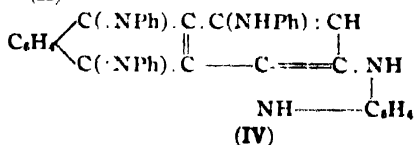

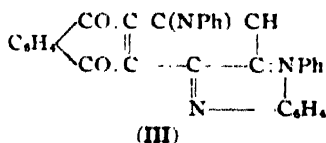

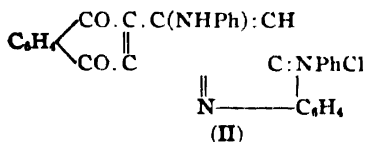

Semipinacolic transformations of trisubstituted glycols. S. KANAO and T. YAGUCHI. *J. Pharm. Soc. Japan* 48, 358-66 (1928).—*l*-Leucine Et ester and PhMgBr gave *l*-isobutyldiphenylethyleneglycol (I), iso-BuCH(OH)CPh₂OH, m. 143.4° , $[\alpha]_D^{20} -135.8^\circ$ (yield 72%). I and cold H_2SO_4 gave optically inactive iso-Bu benzohydril ketone (II), iso-Bu COCHPh₂, b. $183-4^\circ$, m. $32-3^\circ$ (yield, 80%). Semicarbazone, m. 168° . Heating of I with $\text{C}_6\text{H}_5(\text{CO})_2\text{O}$, citric acid or $(\text{CO}_2\text{H})_2$ gave an oil ($b_D^{18} 185^\circ$, $d_4^{20} 1.0269$, $n_D^{20} 1.553$) from which the semicarbazone of II (m. 168°) and that (m. $147-8^\circ$) of isobutyldiphenylacetalddehyde (V) were isolated. V is identical with the compd. prepd. by Tiffeneau and Orekhoff (C. A. 18, 70), who obtained it by heating *dl*-isobutyldihydrobenzoin (IX) with $(\text{CO}_2\text{H})_2$. Lagrave (*Ann. chim.* [10], 8, 400) obtained a mixt. of II and V by distn. of isobutyldiphenylethylene oxide (VI) ($b_D^{17} 196-7^\circ$, $d_4^{20} 1.035$, $n_D^{18} 1.5555$) which was prepd. by the action of BzO_2H on $\text{Me}_2\text{CHCH}_2\text{CH: CPh}_2$ (III). It is remarkable that the oil obtained by heating I with poly- CO_2H acids and L.'s product (VI) have the same phys. properties. For this reason, it was suspected that the heating of I with poly- CO_2H acids converts I into VI which on account of its instability splits into II and V. To make this point clearer, *l*-diphenylmethylaminopentanol (VIII), $\text{Me}_2\text{CHCH}_2\text{CH}(\text{NH}_2)\text{CPh}_2\text{OH}$, was methylated to obtain the quaternary base (VII), iso-BuCH(NMe₃)OH)CPh₂OH, and upon subsequent Hofmann decomposition, isobutyldiphenylethylene oxide (IV), $b_D^{17} 174-5^\circ$, $d_4^{20} 1.0479$, $n_D^{20} 1.5636$, $[\alpha]_D^{20} 10^\circ$, was obtained. From IV, 2 semicarbazones, one m. 168° and the other m. $147-8^\circ$, were isolated. The above facts show that compds. of the type represented by IV or VI are very unstable. Besides the compds. given above, the following new compds. are described: *l*-isobutyldiethylethyleneglycol (XI), $b_D^{18} 111-3^\circ$, m. about $48-52^\circ$, $[\alpha]_D^{18} -27.7^\circ$ (CHCl_3), from *l*-leucine Et ester and EtMgBr ; diphenylurethan, m. 122° . 3-Ethyl-6-methylheptan-4-one, b. $188-92^\circ$, from

XI and concd. H_2SO_4 . *l*-Isobutylidimethylethyleneglycol (**XII**), b_m 111–2°, $[\alpha]_D^{18}$ 22.98° (CHCl_3), from *l*-leucine Et ester and MeMgBr ; *diphenylurethan*, m. 186°. *2,5-Dimethylhexan-3-one*, b. 148°, from **XII** and concd. H_2SO_4 . NAO UYRI

Condensation of aldehydes with phenols. II. *m*-Nitrobenzaldehyde- β -naphthol. OTTO DISCHENDORFER. Tech. Hochschule, Graz. *Monatsh.* 49, 133–45 (1928); cf. *C. A.* 22, 72.—The m. p. curve of β - $\text{C}_{10}\text{H}_7\text{OH}$ and *m*- $\text{O}_2\text{NC}_6\text{H}_4\text{CHO}$ shows a eutectic at 47.5° (17.5% β - $\text{C}_{10}\text{H}_7\text{OH}$) and a 2nd at 61.5° (47% β - $\text{C}_{10}\text{H}_7\text{OH}$). On mixing 0.302 g. *m*- $\text{O}_2\text{NC}_6\text{H}_4\text{CHO}$ and 0.288 g. β - $\text{C}_{10}\text{H}_7\text{OH}$ in ligroin, the compd., m. 61.5°, crystallizes out as yellow needles; the same compd. results on melting equimol. amts. of the 2 components at 70°. *m*-Nitrobenzaldehyde- β -naphthol (**I**) results in 80% yield by treating 9 g. *m*- $\text{O}_2\text{NC}_6\text{H}_4\text{CHO}$ and 16.8 g. β - $\text{C}_{10}\text{H}_7\text{OH}$ in 180 cc. AcOH with 18 cc. concd. HCl; soln. in 6% NaOH or KOH gives the resp. salts; *dibenzoate*, m. 193–4°; *di-Me ether*, pale yellow, m. 216°. **I** (5 g.) in 75 cc. EtOH and 75 cc. 10% NaOH, treated with $\text{Br-H}_2\text{O}$ as long as a ppt. formed, gives 76% of the *dehydro deriv.*, orange, m. 221–2°; *oxime*, m. 216–7° (decompn.). Heating 10 g. **I** in 400 cc. AcOH with 80 cc. concd. H_2SO_4 and 80 cc. AcOH 1 hr. at 100° or using the components in the same way, gives *ms*-[3-nitrophenyl]dinaphthopyran (**II**), pale yellow, m. 223–4°. With H_2SO_4 or better with FeCl_3 , there results from **II** *ms*-[3-nitrophenyl]dinaphthopyranol (**III**), m. 286–7° (decompn.); the *chloride ferrichloride*, red with a metallic luster, m. 204°; *chloride-HCl*, red with a greenish metallic luster, darkens 255°, m. 281° (decompn.); *chloride mercurichloride*, bright red, m. 286° (decompn.); *perbromide*, red, m. 225° (decompn.); *perchlorate*, red, m. 307° (decompn.). The HCl salt of **III** and abs. EtOH give the *Et ether*, m. 266–7°; *Me ether*, m. 256–7°. **II**, boiled with Zn and AcOH for 8 hrs, gives the *3-acetamido deriv.*, crystg. with 0.5 AcOH, m. 140–50°, and then 246–7°; the *3-amino deriv.*, m. 242–3°.

Melting point of 2-chloroanthraquinone. MAX PHILLIPS. Bur. of Chemistry. *Ind. Eng. Chem.* 20, 874 (1928).—The m. p. of 2-chloroanthraquinone was incorrectly reported as 204° (cf. *C. A.* 19, 2335). It is 212.4°. T. S. CARSWELL

Anthraquinone dichlorodiimine and its compounds with the amines. A. A. SANIN. *J. Russ. Phys.-Chem. Soc.* 59, 867–75 (1927).—A suspension of 1,4-(H_2N) $_2\text{C}_{14}\text{H}_6\text{O}_2$ in an excess of HCl is allowed to stand for 1 hr. with excess $\text{Ca}(\text{OCl})_2$. (NCl) $_2\text{C}_{14}\text{H}_6\text{O}_2$ (**I**), seps. and is recrystd. from CCl_4 in orange prisms, m. 155–6°. It is easily sol. in PhNO_2 and $\text{C}_6\text{H}_5\text{N}$ with a red-violet color, brown-yellow in EtOH and AcOH, turns violet on heating as a result of the formation of the amine, sol. in concd. H_2SO_4 , ppts. on addn. of H_2O . **I** dissolves in alkalis and is reduced to the amine by NaHSO_3 , or by Sn and HCl. The corresponding chlorimines were also prepd. from 1,4,5,8-(H_2N) $_4\text{C}_{14}\text{H}_6\text{O}_2$, 1,5,4,8-(H_2N) $_2(\text{HO})_2\text{C}_{14}\text{H}_6\text{O}_2$ and 1,4- $\text{H}_2\text{N}(\text{HO})\text{C}_{14}\text{H}_6\text{O}_2$. **I** reacts readily with phenols and amines; 15 g. PhNH_2 boiled for 5 hrs. with 1 g. of **I** in the presence of anhyd. AcONa and $\text{Cu}(\text{OAc})_2$ yields 1,4-(H_2N) $_2\text{C}_{14}\text{H}_6\text{O}_2$ and 1.6 g. of residue insol. in aq. HCl. Recrystd. from EtOH, it m. 280° and lost Cl on treatment with NH_3 giving a base, m. 204–6°. The compds. are insol. in H_2O , sol. in org. solvents and concd. H_2SO_4 . The formulas **II** and **III** have been assigned to this quinazonium compd. and its base. The portion of the residue insol. in EtOH (0.18 g.) did not contain Cl; it crystd. from a $\text{C}_6\text{H}_5\text{N}$ -EtOH mixt. in brwn-black needles, m. 234–5°. The compn. corresponds to formula IV.

BASIL C. SOYENKOFF

Active constituent of the true coto bark. Constitution of cotoin. ERNEST SPÄTH and FRITZ WESSELY. *Univ. Wien. Monatsh.* 49, 229–40 (1928).—The methylation of cotoin with CH_3N_3 gives only 1 Me deriv., m. 97–8°; MeCHN_3 likewise gives only 1 Et deriv., m. 91–2°. That the free HO is adjacent to the CO group is shown by the

formation of 3,5-dimethoxy-2-phenylcoumarone; the Et ether with $\text{BrCH}_2\text{CO}_2\text{Et}$ gives a coumarone deriv., $\text{C}_{17}\text{H}_{16}\text{O}_3$, m. 108–9.5°. The di-Et ether of cotoin, $b_{10}\text{m}$ 160–70°, m. 82–3°; reduction with Zn dust and alc. KOH gives the alc. 2,6,4-diethoxymethoxy-phenylphenylcarbinol (I), m. 104–5°. The methylation of the Et ether and the ethylation of the Me ether give the same product, methylethylcotoin, m. 103–4°; the corresponding alc. (II), m. 80–1°. Oxidation of I with CrO_3 gives 2,6-diethoxyquinone, m. 127–8°, while II gives 2-methoxy-6-ethoxyquinone, m. 134–5°, also obtained by the oxidation of phloroglucinol Me Et ether, m. 50–1°. These facts support the formula 2,6,4-(HO)- $\text{C}_6\text{(MeO)}_2\text{C}_6\text{H}_2\text{Bz}$ for cotoin.

C. J. WEST

Condensation of furfural with acid amides. KARL BEAUCOURT, Hochschule Bodenkultur, Wien. *Monatsh.* 49, 1–7(1928).— HCONH_2 and furfural (I), heated in a CO_2 stream, give a dark resin. AcNH_2 and I give 40% of *furfurylidenediacetamide*, m. 197° (decompn.); with dil. HCl as the condensing agent, 25% yields are obtained; a Ag salt could not be prepd., the compd. being oxidized and metallic Ag being liberated. The *dipropionamide*, m. 195° (decompn.), results in 35% yields; the *dibutyramide*, m. 181° (decompn.), is formed in 35–40% yields; the *dibenzamide*, decomp. 185°, results in 30–35% yields.

C. J. WEST

Synthesis of tetrahydrofurylpropylamine. R. TAKAMOTO AND T. HIROHASHI, Tokio Imp. Univ. *J. Pharm. Soc. Japan* 48, 446–50(1928).—Condensation of $\text{C}_4\text{H}_8\text{OCHO}$ and MeCHO in 20% NaOH gave 71–2% *furylacrolein* (I), m. 51.5°. I and NH_2OH gave 98% of the oxime, (II), m. 110–1°. The reduction of II in EtOH-AcOH with Na-Hg (Goldschmidt, *Ber.* 20, 728) gave 93% *furylpropylamine* (III), $b_{14}\text{m}$ 172.5–3.0°, b_{20} 34–5°; *chloroplatinate*, yellow, m. 179–80°; *picrate*, bright yellow, m. 165–6°; *picrolonate*, yellowish brown, m. 231–2°. The reduction of II or III in EtOH-AcOH with H_2 and PtO_2 using FeCl_3 as a promoter gave 88–9% *tetrahydrofurylpropylamine*, $b_{14}\text{m}$ 186–7°, b_{20} 46–7°. *Chloroplatinate*, yellow, m. 171–2°; *picrate*, yellow, m. 136–7°; *picrolonate*, yellowish brown, m. 176–7°.

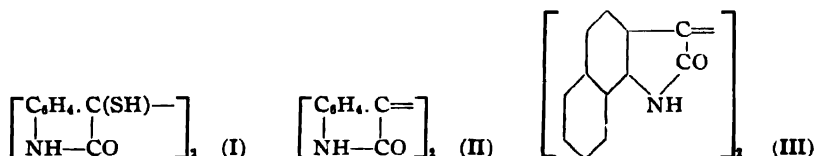

NAO UYEI

The isomerism of heterocyclic nitrogen compounds. N. POTOKHIN, *J. Russ. Phys.-Chem. Soc.* 59, 761–817(1927).—Alkaloids can be regarded as decompn. products of protein; the $\text{C}_8\text{H}_8\text{N}$ and $\text{C}_8\text{H}_7\text{N}$ groups probably result from HCHO and the fission products of proteins (Pictet). A detailed review of the literature is followed by expts. on the condensation of HCHO with hydrogenated N heterocyclics. The action of HCO_2Et on *indolemagnesium iodide*.—To 1.2 g. Mg activated with a little I_2 in 10 cc. abs. PhH are added 1 cc. abs. Et_2O and 8.5 g. EtI . The mixt. is kept at 70° for 2–3 hrs., cooled in snow, and 3 g. indole in 8 cc. PhH are introduced with shaking and cooling (about 600 cc. C_2H_4 are liberated) followed by 10 cc. HCO_2Et . The mixt. is acidified with AcOH , H_2O and Et_2O added. The Et_2O layer is shaken with Na_2CO_3 soln. and Et_2O distd. off. $\text{C}_8\text{H}_7\text{N}$ is removed by treatment with picric acid in PhH. *N-Formylindole*, HCNCC_8H_6 , b_{15} 125–6°, b_{18} 136–7°, m. 52°, $n_D^{18.5}$ 1.6200, $d_4^{18.5}$ 1.750, remains (yield 90%). When HCO_2Et is added without cooling and the mixt. heated to 80–90°, 1–2 g. of the β -aldehyde, $\beta\text{-OHCC}_8\text{H}_6\text{N}$, m. 194°, results. The action of HCO_2Et on $\alpha\text{-MeC}_8\text{H}_6\text{NMeGI}$.— $\alpha\text{-MeC}_8\text{H}_6\text{NMeGI}$, similarly prepd., is a viscous liquid, b_{15} 155°, n_D^{16} 1.6170, d_4^{16} 1.1353. When HCO_2Et is added at 70–75°, $\alpha,\beta\text{-C}_8\text{H}_6\text{NMeCHO}$, m. 198°, is obtained in small quantities. The action of HCO_2Et on *pyrrolemagnesium iodide*.—To 30 g. EtI , 30 cc. abs. PhH and 2 cc. abs. Et_2O are added 5.6 g. Mg and a little I_2 . Upon the soln. of Mg, 13 g. $\text{C}_4\text{H}_7\text{N}$ and 8 cc. PhH are introduced with cooling; 40 cc. HCO_2Et is added drop by drop and the mixt. warmed on the water bath for 10–15 min., decompd. with ice and neutralized with AcOH . The dry Et_2O ext. is fractionated *in vacuo*. A 33–5% yield of $\alpha\text{-OHCC}_8\text{H}_6\text{N}$ is obtained, b_{15} 114°, n_D^{16} 1.5939, solidifies on standing. The oxime, m. 163°. The action of AcOEt on $\text{IMgC}_8\text{H}_7\text{N}$.— AcOEt is added at 85° and heating continued for 30 min. The mixt. is extd. with Et_2O as usual, the Et_2O distd. off and the residue treated with picric acid in PhH to remove $\text{C}_8\text{H}_7\text{N}$ and $\beta\text{-AcC}_8\text{H}_6\text{N}$, leaving $\text{N-AcC}_8\text{H}_6\text{N}$ (2.8 g. from 3 g. $\text{C}_8\text{H}_7\text{N}$), b_{10} 144–5°. The picrate is decompd. with Na_2CO_3 and washed with PhH, the insol. $\beta\text{-AcC}_8\text{H}_6\text{N}$ being recrystd. from hot PhH (m. 189°). The decompn. of *N-OHC- and N-AcC}_8\text{H}_6\text{N}* at high temps.— $\text{N-OHC}_8\text{H}_6\text{N}$ (2 g.) in a sealed tube at 300° yields after 6 hrs. 250 cc. CO_2 , 1.8 g. $\text{C}_8\text{H}_7\text{N}$ and a few crystals solid at 300°. $\text{N-AcC}_8\text{H}_6\text{N}$ (2.6 g.) after 12 hrs. at 300–50° gave CO_2 and 0.15–0.2 g. quinoline besides the unchanged compd. The condensation of $\text{C}_8\text{H}_7\text{N}$ with HCHO .—Equimol. quantities of the amine and (HCHO) $_4$ were heated in a sealed tube to 140–50° for 6 hrs. $\text{N-MeOC}_8\text{H}_6\text{N}$, b_{10} 55–6° and ($\text{N-C}_8\text{H}_6\text{N})_2\text{CH}_2$, b_{10} 94–5°, were obtained upon drying and fractionation. The residue was dry-distd., free $\text{C}_8\text{H}_7\text{N}$ and probably, $\alpha\text{-MeOC}_8\text{H}_6\text{N}$ being isolated from the distillate. The condensation of $\text{C}_8\text{H}_{11}\text{N}$ with HCHO .—Equiv. quantities were heated in a

sealed tube to 150° for 6 hrs. CO₂ and a small quantity of water-sol. liquid sepd. The oil layer contained MeC₃H₁₀N, b₃₅ 33-5° (probably a mixt. of α - and *N*-compds.) and (N-C₃H₁₀N)₂CH₂, b₁₋₁ 120-5°, d₄²⁰ 0.9371, d₄¹⁵ 0.9335, n_D¹⁵ 1.4883. The condensation of (CH₃)₂NH with HCHO.—After 5 hrs. in a sealed tube at 120°, equimol. quantities of (CH₃)₂NH, b. 65-70°, and HCHO gave CO₂ and C₆H₁₄N₂, b. 185°, d₄¹⁰ 0.9110, n_D¹⁰ 1.4685.

BASIL C. SOYENKOFF

A new reaction of the disulfisatides. A. WAHL AND LOBECK. *Compt. rend.* 186, 1303-5(1928); cf. C. A. 21, 2472.—A direct transformation of a disulfisatide (I) into an isoindigotin (II) can be realized by heating with CuCl in AcOH on the water bath. The yield is 50-60%. The reaction has a general character. When the indigotin is little sol. in org. solvents, CuS cannot be removed by filtration; oxidation in wet air or treatment with hot concd. HCl must be used. Naphthodisulfisatide, which is insol. in org. solvents and thus cannot be completely freed of S, yields α -dinaphthoisoindigotin (III).

A. L. HENNE

Thiazole derivatives. HERBERT WM. STEPHEN AND FORSYTH JAMES WILSON. Royal Tech. College, Glasgow. *J. Chem. Soc.* 1928, 1415-22; cf. C. A. 21, 245.—CS(NHN:CMPh)₂ and MeCHBrCO₂Et with EtONa give 90% of 3-phenylmethylmethyleneamino-2,4-diketotetrazole-5-methyltetrahydrothiazole-2-phenylmethylmethylenehydrazone, PhCMe:NN:C.N(N:CPhMe).CO.CHMe.S, m. 150°; the 5-Et deriv.,

m. 110° (90% yield from EtCHBrCO₂Et); the 5-Ph deriv., m. 165° (80% yield from PhCHBrCO₂Et); these could not be satisfactorily hydrolyzed by dil. or concd. HCl. H₂NN:C(SH)NHNH₂ and ClCH₂CO₂Et with EtONa give an impure 3-amino-2,4-diketotetrazole-2-hydrazone, H₂NN:C.N(NH₂).CO.CH₂.S, m. 119-20°, whose

dibenzylidene deriv., m. 138°, has been previously described; MeCHBrCO₂Et gives the 5-Me deriv., m. 100-1°, whose dibenzylidene deriv., m. 114°; the 5-Et deriv., m. 92-3°, could not be obtained pure (dibenzylidene deriv., m. 106°). o-Phenyleneithiocarbamide, MeCHBrCO₂Et and EtONa give 90% of Et benziminazolyl-2- α -thiolpropionate (I), m. 100°; the butyrate, m. 108-9°; the free acid, m. 176° (decompn.). Attempted ring closure with I, by using Na wire in C₆H₆, gave the free acid, m. 179° (decompn.). Benzimidazole-2-thioglycolic acid, m. 215°. Trimethylenethiocarbamide and ClCH₂CO₂Et in C₆H₅N give Et 1,4,5,6-tetrahydropyrimidine-2-thioglycolate, m. 256°. Benzoylenethiocarbamide, ClCH₂CO₂Et and EtONa give a complex mixt., from which was isolated a small quantity of Et 4-keto-3,4-dihydroquinazoline-2-thioglycolate, m. 149°. H₂NCSNHNHCSNH₂ and ClCH₂CO₂Et are considered to give 2,4-diketotetrazolethiazole-2-ketazine (cf. Frerichs, C. A. 4, 2294; 7, 3476). H₂NCSNHNHCONH₂ and ClCH₂CO₂H give 2,4-diketotetrazolethiazole-2-semicarbazone, m. 221-2° (decompn.). Acetophenone 8-phenylthiosemicarbazone, pale yellow, m. 195° (95% yield). C. J. WEST

Rhodanines and related compounds. RUDOLF ANDREASCH. Tech. Hochschule, Graz. *Monatsh* 49, 122-32(1928).—In the reduction of benzalphenylrhodanine with Zn and HCl, the S of the thioketo group is replaced by H₂, giving 4-keto-3-phenyl-5-benzaltetrahydrothiazole, m. 206°. Similarly were prepd. 4-keto-3-phenyltetrahydrothiazole, m. 115° and the 3-p-tolyl deriv., m. 143°. The reduction product of rhodanine is apparently hydrolyzed during the concn. of the reaction product, HSCH₂CO₂H being isolated. Diphenylthiohydantoin and BzH in AcOH give 85% of benzaldiphenylthiohydantoin, m. 206°; attempted reduction led only to the splitting off of PhNH₂. Condensation of PhNHCS₂NH₂ and HO₂CCH₂CHBrPh gives 2-thioketo-3,6-diphenyl-4-ketotetrahydrothiazine, m. 122°. PhNCS and HO₂CCH(SH)CH₂Ph gives benzal- γ -phenylrhodanine, m. 118-9°. Heating PhNHCOCH₂SH with COCl₂ gives a dark colored resin; BzH gives benzaldithioglycolic anilide, m. 178°. Rhodanine and Me₂CHCHO give isobutylidenerhodanine, m. 128°; isovalerylene deriv., m. 83-5°. Isopropylthiohydantoin, m. 229°. o-Chlorobenzal- γ -phenylrhodanine (I), yellow, m. 140-1°; o-chlorobenzalrhodanine, m. 169°; α -sulphydryl-o-chlorocinnamic acid, m. 119-20°, by

hydrolysis of I. A table is given of the thioglycolic acid reaction, the compds. being classified according as to whether they give a red, green or blue color with Fe.

C. J. WEST

Chemistry of the 1,2,3-triazoles. I. Reactions in the heating of aryl azides in sodium alcoholate solutions in primary alcohols. ALFRED BERTHO AND FRITZ HÖLDER. Univ. Heidelberg. *J. prakt. Chem.* 119, 173-88(1928).—*p*-Xylyl azide (14.7 g.) and 6.9 g. Na in 111 g. PrOH, heated 65 hrs. at 108°, give 1100 cc. N and 10% of 1-*p*-xylyl-4-methyl-1,2,3-triazole, *b*₁₆ 165-70°, m. 57.5°; iso-AmOH gives 2.5% of the 4-*iso*-Pr deriv., m. 118°; PhCH₂OH gives 26% of the 4-Ph deriv., m. 129°; EtOH or BuOH did not give a triazole. Attempts are reported to det. the constitution of the compd., m. 282° (decompn.), which is formed in the reaction with PhN₃; the mol wt., 128.9, does not correspond to the analysis; since this does not result in the above reactions, the matter is dropped. II. Decomposition of 1-*p*-xylyl-1,2,3-triazole-4,5-dicarboxylic acid according to Curtius. *Ibid* 189-98.—*Di-Me* 1-*p*-xylyl-1,2,3-triazole-4,5-dicarboxylate, m. 86°, results in 82% yield from 5 g. (:CCO₂Me)₂ and 5 g. *p*-MeC₆H₄N₃ at 90°; the free acid, m. 151° (evolution of CO₂), results quant. on heating 4 hrs. with KOH in 70% EtOH. The ester and N₂H₄·H₂O in EtOH give 80% of the dihydrazide, m. 133.5° (diacetonil deriv., m. 207°; dibenzal deriv., m. 186°), and a sec. hydrazide, C₁₂H₁₄N₁₀O₄, which crysts. with 1 AcOH and m. 286° (decompn.). HNO₃ with the dihydrazide gives 92% of the 4-azide 5-isocyanate, decomp. 150°; cooking with EtOH gives a resin, while MeOH gives a sym. urea, C₁₂H₂₀N₁₄O₄, m. 164° (decompn.) and a large quantity of resin, from which nothing could be isolated.

C. J. WEST

Constitution of the anthochlor of the yellow dahlia. LEOPOLD SCHMID AND ALFRED WASCHKAU. Univ. Vienna. *Monatsh.* 49, 83-91(1928).—The dyestuff of the yellow dahlia is *apigenin*; details are given for its isolation; it crysts. with 0.5 H₂O, m. 347-8° (color.); the *Ac* deriv., m. 181-2°; the *di-Me* ether, m. 170-1°. Alk. degradation gives *p*-HOC₆H₄Ac and 1,3,5-C₆H₃(OH)₃. The KOH melt gives *p*-HOC₆H₄CO₂H.

C. J. WEST

Neocyanine. FRANCES M. HAMER. Ilford, Ltd. *J. Chem. Soc.* 1928, 1472-8; cf. Dundon, Schoen and Briggs, *C. A.* 20, 1764.—Lepidine-EtI (5 g.), 5.5 g HC(OEt)₂ and 20 g. C₆H₅N, boiled 3 hrs. and the product (0.89 g.) recrystd. from 1000 cc. EtOH, give 0.72 g. (17%) of neocyanine-EtI (I), which probably has the formula C₂₃H₁₇N₃I₂, dull-green powder, m. 284° (decompn.). The C₆H₅N mother liquor yields 42% of 1,1'-diethyl-4,4'-carbocyanine iodide (II). From *p*-MeC₆H₄SO₃Et, there results 26% I and 7% II. If the reaction product is decompd. with NaBr soln., there results 37% of neocyanine-EtBr, green and gold crystals, m. 291° (decompn.), and 5% of the bromide of II. Lepidine-MeI and HC(OEt)₂ gave no neocyanine. Neocyanine-MeBr, bright Cu color, m. 288° (decompn.) (41% yield). From condensations carried out with lepidine-*p*-MeC₆H₄SO₃Et, it appears that in the presence of much C₆H₅N there is a tendency to the formation of cryptocyanine rather than of neocyanine, but that with a small quantity of C₆H₅N the reverse is the case. All 3 neocyanines show a very similar sensitizing action.

C. J. WEST

Synthesis of anthocyanins. IV. Constitution of *o*-benzoylphloroglucinaldehyde. ALEXANDER ROBERTSON, ROBERT ROBINSON AND ADA MARGARET STRUTHERS. Univ. of Manchester. *J. Chem. Soc.* 1928, 1455-9; cf. *C. A.* 21, 3195.—The structure of *O*-benzoylphloroglucinaldehyde (I) as 4,6-dihydroxy-2-benzoyloxybenzaldehyde is confirmed by its synthesis from *O*-benzoylphloroglucinol (II), HCN and HCl; although the yield was poor, no isomers could be isolated; MeI and K₂CO₃ give the 4,6-*di-MeO* deriv., m. 148°. Similarly, II, anisoylacetaldehyde and HCl give 7-hydroxy-5-benzoyloxy-4'-methoxyflavylium chloride, previously obtained from I. *m*-Xylorcyllaldehyde, *p*-AcC₆H₄OMe and HCl in HCO₂H give 5-hydroxy-4'-methoxy-6,8-dimethylflavylium chloride, reddish violet needles, which appear red by transmitted light, crystg. with 3H₂O; the dehydrated product is redder in color; the color base gives a blue soln. in C₆H₆. V. Synthesis of 3,β-glucosidylpelargonidin chloride, which is believed to be identical with callistephin chloride. A. ROBERTSON AND R. ROBINSON. *Ibid* 1460-72.—*p*-HOC₆H₄COCH₂OH and ClCO₂Me in H₂O give *ω*-hydroxy-4-methylcarbonatoacetophenone, m. 84°; 4-*Ac* deriv. (III), m. 95-6°; 4-*Bz* deriv. (IV), m. 140-1°; the *di-Bz* deriv., m. 180-2°. IV (4.5 g.) and 12 g. *O*-tetraacetyl-α-glucosidyl bromide (V) in 80 cc. C₆H₆, treated with 10 g. Ag₂CO₃ at 35°, give 5 g. *ω*-*O*-tetraacetyl-β-glucosidory-4-benzoyloxyacetophenone, m. 147°; attempts to condense this with I were not successful. III and V similarly give the 4-*Ac* deriv. (VI), m. 132°. *ω*-*O*-Tetraacetyl-β-glucosidory-4-methoxyacetophenone, m. 133°, from V and anisoylcarbinol. VI (1 g.) and 1.5 g. I in 30 cc. CHCl₃ and 100 cc. Et₂O, satd. with HCl at room temp., give 0.4 g. pure and 0.6 g. impure 3-*O*-tetraacetyl-β-glucosidory-7-hydroxy-5-benzoyloxy-4'-acetoxyflavylium chloride,

red plates with brilliant green reflex; the orange-red EtOH soln. shows a green fluorescence; NaOH or concd. aq. Na_2CO_3 gives a purple-violet color. With 8% NaOH at 10° for 3 hrs., followed by acidification with 7% HCl until the concn. of the HCl was 2%, purification through the Pb salt and addn. of cold satd. aq. picric acid, there results 3- β -glucosidylpelargonidin picrate, bright red plates with a brilliant golden reflex; with 5% MeOH-HCl this gives the chloride, which crysts. with $2\text{H}_2\text{O}$ and in every respect appears to be identical with the callistephin chloride of Willstätter and Burdick. If this be true, then pelargonin, peonin and cyanin are 5- or 7-saccharides, the weight of evidence favoring the 5-saccharide configuration. C. J. WEST

Synthesis of pyrylium salts of anthocyanidin type. XV. The synthesis of cyanidin chloride by means of *O*-benzoylphloroglucinaldehyde. ALEXANDER ROBERTSON AND ROBERT ROBINSON. Univ. Manchester. *J. Chem. Soc.* 1928, 1526-32; cf. *C. A.* 22, 90.— ω ,3,4-Triacetoxycetophenone, m. 95° , from the 3,4-(HO) $_2\text{C}_6\text{H}_3\text{COCH}_2\text{Cl}$, Ac_2O and AcOK; 3.5 g. of the ketone, 2.5 g. *O*-benzoylphloroglucinaldehyde (I), 50 cc. AcOEt and 20 cc. EtOH, cooled and satd. with HCl, give 5 g. 5-*O*-benzoylcyanidin chloride, red, crystg. with $1.5\text{H}_2\text{O}$; the EtOH soln. is bluish red and becomes KMnO_4 -colored on diln; addn. of H_2O gives a pink color, rapidly decolorized on heating. FeCl_3 in EtOH gives an intense deep blue color, becoming reddish violet on diln. with H_2O . The chloride (5 g.), added to 65 cc. cold 8% aq.-EtOH NaOH in an atm. of N, allowed to stand 3 hrs., then treated with 100 cc. concd. HCl and heated at 60° , gives 3 g. cyanidin chloride, identical with the natural chloride. There are appended remarks on the paper of Malkin and Nierenstein (*C. A.* 22, 2358), regarding the constitution of cyanin chloride.

XVI. Synthesis of pelargonidin chloride by means of *O*-benzoylphloroglucinaldehyde. A. ROBERTSON, R. ROBINSON AND JIRO SUGIURA. *Ibid* 1533-7.—I (7.7 g.) and 7 g. 4-AcOC $_6\text{H}_4\text{COCH}_2\text{OAc}$ in 150 cc. AcOEt, satd. with HCl, gives, after 3 days, 9.5 g. 5-*O*-benzoylpelargonidin chloride, crystg. with $1.5\text{H}_2\text{O}$, plates having a maroon color in mass and deep blue luster; EtOH gives a violet soln.; the pseudo base is formed in very dil. EtOH solns. or on the addn. of H_2O ; Na_2CO_3 gives a bright violet soln. but the color, even in 50% EtOH, is pure blue. Hydrolysis gives pelargonidin chloride. $\text{MeOCH}_2\text{COCH}(\text{OMe})\text{CO}_2\text{Et}$ (22.8 g.), added to 2.8 g. in 150 cc. Et_2O and the soln. treated with 24.1 g. 3,5-(MeO) $_2\text{C}_6\text{H}_3\text{COCl}$, gives 6.7 g. ω ,3,5-trimethoxyacetophenone (II), b $_p$ $127-37^\circ$, m. 42° ; semicarbazone, m. $149-9.5^\circ$. I (2.3 g.) and 2 g. II in 500 cc. Et_2O , satd. with HCl, give 0.84 g. 7-hydroxy-5-benzoyloxy-3,3',5'-trimethoxyflavylium chloride, brownish crimson, crystg. with $2\text{H}_2\text{O}$; hydrolysis with 10% aq. NaOH, or the condensation of II and *O*-triacytlyphloroglucinaldehyde in HCO_2H with HCl gives 5,7-dihydroxy-3,3',5'-trimethoxyflavylium chloride, crystg. with $0.5\text{H}_2\text{O}$, dark violet-brown prisms, which are reddish brown by transmitted light and exhibit a Cu glance. Attempts to demethylate this compd. and to obtain the pure penta-HO deriv. were unsuccessful.

XVII. Synthesis of peonidin chloride by means of *O*-benzoylphloroglucinaldehyde. SHINZO MURAKAMI AND R. ROBINSON. *Ibid* 1537-41.—I (2.94 g.), 2.58 g. 4,3-AcO(MeO) $\text{C}_6\text{H}_3\text{COCH}_2\text{OAc}$ and 75 g. AcOEt, satd. with HCl, give 3.55 g. 5-*O*-benzoylpeonidin chloride, crystg. with $0.5\text{H}_2\text{O}$, scarlet; solus. in MeOH and EtOH are crimson, becoming violet on diln. with alc. and colorless on great diln. and warming. The salt is very sparingly sol. in boiling H_2O and hot 0.5% HCl. The soln. in aq. Na_2CO_3 is pure blue, greenish blue in thin layers and purplish blue in thick layers. The red crystals, dissolved in MeOH and warm 15% HCl added, changed to beetle-green prisms, yellowish brown by transmitted light, and gave a violet-red smear on paper; they contain $3\text{H}_2\text{O}$. Hydrolysis (acid or alk.) gives peonidin chloride, which was compared with a natural sample.

XVIII. Synthesis of malvidin chloride. WM. BRADLEY AND R. ROBINSON. *Ibid* 1541-69.— Bz_2O in C_6H_6 added to $\text{BzCHNaCO}_2\text{Et}$ in Et_2O at 0° gives *Et* benzoylbenzoyloxyacetate, m. 61° ; in EtOH it gives no color with FeCl_3 and no Cu deriv. could be isolated; on heating with H_2O at 200° for 2 hrs., there results $\text{PhCOCH}_2\text{OBz}$, m. $114-5^\circ$; with dil. H_2SO_4 this gives an unsatisfactory yield of BzCH_2OH . 3,4,5-(MeO) $_3\text{C}_6\text{H}_2\text{COCH}_2\text{CO}_2\text{Et}$ (for which a modified method of prepn. is given), transformed into the K salt in C_6H_6 and treated with Bz_2O , gives *Et* 3,4,5-trimethoxybenzoylbenzoyloxyacetate, m. 107° ; on heating with H_2O at 200° for 14 hrs., there results ω -benzoyloxy-3,4,5-trimethoxyacetophenone, m. $98-100^\circ$; this compd. exhibits little tendency to condense with I to give a flavylium salt. *Et* trimethoxybenzoyloxyacetate, m. 88° ; hydrolysis by boiling 10% H_2SO_4 for 3 hrs. gives ω -hydroxy-3,4,5-trimethoxyacetophenone, m. $87-8^\circ$ (diphenylhydrazone of 3,4,5-trimethoxyphenylglyoxal, yellow, m. $137-8^\circ$). With I and HCl in Et_2O , there results 3,5,7-trihydroxy-3',4',5'-trimethoxyflavylium chloride, crimson needles, crystg. with 1 mol. H_2O . HBr in AcOH gives a mixt. of malvidin and delphinidin or, more probably, delphinidin 3'-Me ether and therefore a synthesis of a more precise nature was undertaken. *O*-Acetylsyringoyl

chloride, m. 126°, (from the acid and PCl_5 in AcCl); with $\text{AcCHNaCO}_2\text{Et}$ gives *Et O-acetylsyringoylacetate*, m. 112–4°; hydrolysis gives *Et syringoylacetate*, m. 92°; FeCl_3 in EtOH gives a bright emerald-green color; $\text{Cu}(\text{OAc})_2$ gives an insol. brown Cu salt. These esters could not be transformed into acyloxy derivs. *Me O-benzylsyringate*, m. 71°, results from Me syringate and PhCH_2Cl and KOH in MeOH . This could not be condensed with AcOEt . *O-Benzylsyringic acid*, m. 157°, from syringic acid and BzCl in 10% aq. NaOH ; the chloride, m. 45°; the amide, m. 152°. *Et O-benzylsyringoylacetate*, m. 97–102°; FeCl_3 in EtOH gives a crimson color. Hydrolysis with NH_3 gives *Et O-benzylsyringoylacetate* (II), m. 67°; FeCl_3 gives a crimson color; the Cu salt is pale green, m. 212°. With Bz_2O_3 this gives ω -benzyloxy-4-benzyl-3,5-dimethoxyacetophenone, m. 105°; this appears to condense with I, although in a sluggish fashion and its behavior is somewhat anomalous. $\text{Pb}(\text{OAc})_4$ and II in AcOH give *Et di-[O-benzylsyringoyl]succinate*, m. 173–6°, a better yield is obtained with the K salt of II. Benzylsyringoyl chloride and CH_3N_2 give ω -diazo-4-benzoyl-3,5-dimethylacetophenone, bright lemon-yellow, m. 122–3° (decompn.); heated with AcOH at 60–70° it gives ω -acetoxy-4-benzoyloxy-3,5-dimethoxyacetophenone, m. 60.5–1°. With I and HCl , this gives 5-benzoylmalvidin chloride, crystg. with 2.5 H_2O , olive-green in mass and exhibits a strong golden luster; the alc. solns. are violet-red, and are readily decolorized on keeping or standing; aq. Na_2CO_3 gives a pure deep-blue soln., which becomes greenish on diln. in H_2O and in EtOH even the addn. of NaOAc gives a pure blue color. Hydrolysis gives malvidin chloride, which is compared with the natural product. Hydrolysis of II by heating with H_2O at 175–80° for 10 hrs. gives 4-benzoyloxy-3,5-dimethoxyacetophenone (III), m. 60–1° (semicarbazone, m. 166°; 2,4-dinitrophenylhydrazones, scarlet, m. 192–3°); HBr in AcOH gives 4-hydroxy-3,5-dimethoxyacetophenone, m. 117°. III and iso- AmNO , in EtONa give the isonitroso deriv., canary-yellow, m. 107–8° (oxime, m. 141–2°). III and I, condensed in AcOEt with HCl , give 5,7,4'-trihydroxy-3',5'-dimethoxyflavylium chloride, crystg. with 1 mol. H_2O , reddish brown, exhibiting a greenish yellow luster when rubbed; the hot aq. soln. is a deep brownish red; the brownish red MeOH soln. is not changed by heating or diln. The reddish violet NaOH soln. changes through deep red to orange and yellow. 4-Hydroxy- ω -3,5-trimethoxyacetophenone, m. 90°, results from $\text{MeOCH}_2\text{COCNa}(\text{OMe})\text{CO}_2\text{Et}$ and acetylsyringoyl chloride; with I it gives the 5-Bz deriv. of 5,7,4'-trihydroxy-3',5'-trimethoxyflavylium chloride (malvidin chloride 3-Me ether), crystg. with 2 H_2O , deep red by transmitted, olive-green by reflected light and possessing a bright yellow luster. Conc'd HCl in MeOH removes the Bz group, giving the malvidin chloride 3-Me ether, dark violet powder with a bright yellow reflex; the cold aq. soln. is blood-red and, if sufficiently dil., decolorizes on standing; the cold sat'd. soln. in 3% HCl is blood-red; the ease of pseudo-base formation in EtOH is greater than with malvidin and the color is immediately and fully restored on acidification.

C. J. WEST

The oxidation of quinoline-8-sulfonic acid. EDWARD SUCHARDA. Lemberg Polytechnic. *Kosmos* 1920–21, 18 pp.; *Chem. Zentr.* 1927, I, 3005–6.—The oxidation of quinoline-8-sulfonic acid with alc. KMnO_4 gives rise to 2 products: (1) a K salt of an addn. compd. (I) prepd. by Zürcher (*Ber.* 21, 180), and (2) the K salt of 7-sulfoisatin (II). I, m. 248°, is decompd. by strong acids; its aq. solns. are fluorescent. Decompd. with conc'd. HCl , I forms 2-amino-3-sulfobenzoic acid (III), m. 263°; its dil. aq. solns. are fluorescent. It is not identical with the compd. prepd. by Limpricht and Ulsar, which they regarded as 3,5- $\text{HO}_2\text{S}(\text{H}_2\text{N})\text{C}_6\text{H}_3\text{CO}_2\text{H}$. With KNO_3 its soln. in conc'd. H_2SO_4 form the internal anhydride of 2-diazo-3-sulfobenzoic acid, $\text{C}_7\text{H}_4\text{O}_5\text{N}_2\text{S}$, m. 150°. Warmed with 20% HCl , this forms 2-hydroxy-3-sulfobenzoic acid, $\text{C}_7\text{H}_4\text{O}_5\text{S} \cdot 2\text{H}_2\text{O}$, m. 213°. Ba salt, $\text{C}_7\text{H}_4\text{O}_5\text{SBa} \cdot \text{H}_2\text{O}$. Na salt, with 2.5 H_2O . With formamide, III forms 4-hydroxy-8-sulfoquinazoline carbonizes without fusing when heated. From II was formed the Ba salt, $(\text{C}_8\text{H}_4\text{O}_4\text{NS})_2\text{Ba}$, and from this in turn 7-sulfoisatin, $\text{C}_8\text{H}_4\text{O}_4\text{NS} \cdot 4\text{H}_2\text{O}$ (II), orange-red, m. 80°, loses its H_2O of crystn. at 197°. It is not identical with the thioisatin prepd. by G. and A. Schlieper (*Ann.* 120, 1), for their Ba salt was different crystallographically and contained H_2O of crystn.

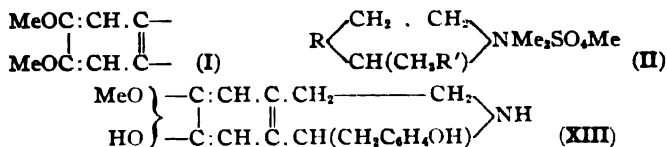

C. C. D.

Amino acid anhydrides. I. Molecular compounds of diketopiperazine with copper halides. TEI-ICHI ASAHINA AND TSURUMATSU DONO. Tokyo Univ. *Bull. Chem. Soc. Japan* 3, 151–6 (1928).—Mol. addn. compds. of diketopiperazine (glycine anhydride) and CuCl_2 or CuBr_2 have been prepd. in 80 or 90% yield, resp. Glycine anhydride-copper chloride crystals, $\text{C}_8\text{H}_{10}\text{O}_4\text{N}_2 \cdot \text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ (I), are light blue rhombic needles; they are partly decompd. in H_2O and alc. In hot solvents, the decompn. proceeds rapidly. I is insol. in, and scarcely decompd. by Me_2CO , C_6H_6 , Me_2O and CHCl_3 . The water of crystn. is expelled at 110° and the compd. turns reddish brown; on further heating it decomp. without melting. It can be recrystd. only from a warm

concd. CuCl_2 soln. by cooling. Glycine anhydride-copper bromide (II), exhibits the same general properties; the crystals are bright green monoclinic prisms, with $2\text{H}_2\text{O}$ of crystn. It was ascertained that similar compds. are formed in H_2O , but their formulas are different than in the solid state. The meaning of these mol. compds. for the chemistry of the proteins is discussed.

A. L. HENNE

Alkaloids of Sinomenium and Coccus. XX. Constitution of coclaurine. III. H. KONDO AND T. KONDO. *J. Pharm. Soc. Japan* **48**, 324-37 (1928).—In paper II, (*J. Pharm. Soc. Japan* No. 538, 1029) the approx. constitution of coclaurine was proposed, but the positions of the OH and MeO groups on the tetrahydroisoquinoline ring still remained uncertain. This paper reports the results of further work on the detn. of the positions of these groups. A complete purification of tetramethylcoclaurine-methin B (III) which was obtained by Hofmann's decompn. of tetramethylcoclaurine methosulfate (II) ($\text{R} = \text{I}$, $\text{R}' = p\text{-C}_6\text{H}_4\text{OMe}$) gave colorless crystals, m. 86° . *HCl* salt, m. $228.5-9.0^\circ$. Since it has lost its optical activity, it should have the constitution $\text{R}(\text{CH}:\text{CHR}')\text{CH}_2\text{CH}_2\text{NMe}_2$ (IIIa) rather than $\text{R}[\text{CH}(\text{CH}_2\text{R}')\text{NMe}_2]\text{CH}:\text{CH}_2$ (IIIb). The oxidation of III in MeOH with KMnO_4 gave 4-MeOC₆H₄CO₂H and an amino acid, $\text{R}(\text{CO}_2\text{H})\text{CH}_2\text{CH}_2\text{NMe}_2$ (IV). Hofmann's decompn. of the methosulfate (V) of IV gave

Me_3N and dimethoxyvinylbenzoic acid (VI), m. 184° . VI, Pd-C and H_2 gave 3,4-dimethoxy-6-ethylbenzoic acid, m. $142-3^\circ$, which was identical with Shinoda's synthetic product (*C. A.* **22**, 772). The above results show that the 2 MeO groups are in the 3,4-positions. In order further to prove that the structure of III as represented by IIIa is correct, the synthesis of III was accomplished. 3,4-(MeO)₂C₆H₃CHO and MeNO_2 gave 3,4-dimethoxy- β -nitrostyrene (VII), m. 142° . The electrolytic reduction of VII gave homoveratrylamine (VIII), whose chloroplatinate m. 196° . 4-MeOC₆H₄CH₂COCl and VIII gave 4'-methoxybenzylhomoveratrylamine (IX), m. 123.5° . IX and POCl_3 gave 1-[4'-methoxybenzyl]-6,7-dimethoxydihydroisoquinoline (X), m. $190-1^\circ$. Picrate, m. 177° . Methiodide, m. 224° . *HCl* salt of X, Pd-C and H_2 gave 1-[4'-methoxybenzyl]-6,7-dimethoxytetrahydroisoquinoline (XI); *HCl* salt, m. 175° . XI and Me_2SO_4 gave *N*-methyl-1-[4'-methoxybenzyl]-6,7-dimethoxytetrahydroisoquinolinemethylmethosulfate (II), m. 175° . Chloroplatinate of the methochloride, m. 174° . Hofmann's decompn. of XII with 30% KOH gave the free amine whose *HCl* salt m. $228.5-9.0^\circ$ and was identical with the *HCl* salt of III. The above results show the structure of coclaurine to be represented by XIII.

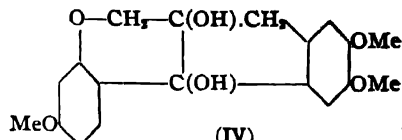

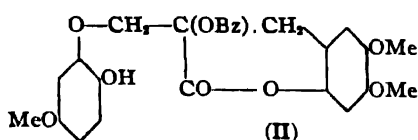

NAO UYRI

The significance of tri-, di- and sesquiterpenes in the chemistry of phytosterols and resins. K. ALB VESTERBERG. Univ. Stockholm *Tschirch-Festschrift* 1926, 4 pp.; *Chem. Zentr.* 1927, I, 894; cf. *C. A.* **21**, 4059.—Triterpene derivs. are probably present fairly often in various resins. Since abietic acid and *d*-pimaric acid yield phenanthrene derivs. when dehydrogenated with S, and since certain resin acids, C₃₀H₅₀O₂, can in all probability be regarded as diterpene derivs., there may be diterpenes which bear the same relation to phenanthrene that certain sesquiterpenes do to C₁₅H₈. A subfossil resin, probably originating from one of the Dipterocarpaceae, gave on distn. with powd. Ni a sesquiterpene, C₁₅H₂₄, b_p $90-2^\circ$, d_4^{20} 0.9153, n_D^{20} 1.5120, M_N 60.75, $[\alpha]_D^{25}$ 1.52° , which was converted by S to a C₁₆H₂ homolog similar to cadalene. In a similar manner sesquiterpenes were obtained from dammar resin and from Kauri copal resin. A sesquiterpene can be isolated from birch tar oil, which can be dehydrogenated to a naphthalene hydrocarbon, C₁₅H₁₄, b. 248° , and it is, therefore, probable that betulol would give a sesquiterpene on dry distn.

C. C. DAVIS

Synthesis of brazilin and hematoxylin and their derivatives. III. WM. HENRY PERKIN, JR., JNANENDRA NATH RAY AND ROBERT ROBINSON. Univ. of Oxford and Manchester. *J. Chem. Soc.* 1928, 1504-13; cf. *C. A.* **22**, 88.—The conversion of deoxytrimethylbrazilone (I) into *o*-trimethylbrazilin has proved a puzzling problem, chiefly because of the remarkable properties of I, which is prone to undergo oxidation; when I is merely shaken with C₆H₅N and aq. NaOH a considerable proportion of the material becomes alkali-sol. in a short time and in the presence of acids there is a strong tendency to form the isobrazilin salt. A stream of dry HCl passed through I in cold CHCl_3 gives chiefly isobrazilin-HCl tri-Me ether; other attempts to add the elements

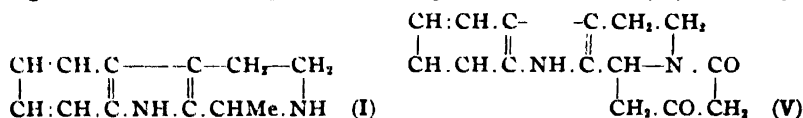

of H_2O or of an acid to I were unsuccessful. The reduction of trimethylbrazilone with $PhNHNH_2$ in EtOH does not proceed satisfactorily but in AcOH, 8 g. gives 4–4.5 g. I and as a by-product, the bright yellow compd., $C_{25}H_{32}O_4N_2$, m. 245° . The action of BzO_2H on I in $CHCl_3$ gives the compd. $C_{25}H_{32}O_8$, to which formula II is ascribed, largely

by analogy with the products derived from brazilin derivs. with H_2O_2 . I in AcOH adds Br, forming a dibromide, dark crimson, which loses Br in vacuum, giving an isobrazilin salt; with an excess of Br, a perbromide, $C_{15}H_{18}O_4Br_6$, is pptd. Zn in AcOH reduces the dibromide to I. Catalytic reduction of I in AcOEt gives the dihydro deriv. (O-trimethylbrazilane), m. 109° , which is oxidized by CrO_3 in AcOH to trimethylbrazilone (III). Reduction of III with Al-Hg in AcOEt gives the compd. $C_{15}H_{20}O_4 \cdot 0.5H_2O$, m. 129° (decompn.); Ac_2O gives a deriv., m. 116° . III and Zn in AcOH give trimethyl-dihydrobrazilone (hydroxy-O-trimethylbrazilin) (IV), m. $167-8^\circ$; with H_2SO_4 it gives isobrazilin tri-Me ether; the most characteristic salt is the anhydro sulfate, deep red needles; the anhydro HCl salt is also crimson but is more sol. than the sulfate. O-Triacetylbrazilone, m. 187° (decompn.); the tri-Bz deriv., m. 205° (decompn.).

C. J. WEST

Synthesis of carboline derivatives. G. TATSUI. Tokyo Imp. Univ. *J. Pharm. Soc. Japan* 48, 453–9 (1928).— β -(β' -Indolyl)ethylamine (Majima and Hoshino, *C. A.* 20, 758) and paraldehyde gave tetrahydroharman (I), $C_{17}H_{18}N_2$, light yellow, m. $179-80^\circ$. HCl salt, decomp. 265° . Chloroplatinate, red, decomp. 257° . It resisted most reducing reactions and by the Schotten-Baumann reaction it gave benzoyltetrahydroharman, m. $168-9^\circ$. I and MeI in a closed tube gave tetrahydro-N-methylharman-HI (II), light yellow, m. $199-200^\circ$. II and AgOH gave the methohydroxide, which was easily and quant. dehydrated in vacuum at 80° to give N-methyltetrahydroharman (III), $C_{18}H_{18}N_2$. III and MeI gave the methiodide. The condensation of I with $CH_2(CO_2Et)_2$ in presence of NaOEt gave di-Et tetrahydroharmanmalonate (IV), $C_{17}H_{18}N_2O_4$,

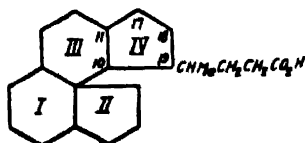

bright yellow, m. $134-5^\circ$, and the free acid, (decomps. 155°) as a by-product, which on heating liberates CO_2 and gives the Ac deriv. of I. IV and NaOEt gave a compd. (decomps. 175°) which gave a positive diazo reaction and probably has the structure represented by V.

NAO UYRE

Dehydration experiments with sitosterol. LEOPOLD SCHMID and MARGOT ZENTNER. Univ. Vienna. *Monatsh* 49, 92–7 (1928); cf. *C. A.* 21f, 3201.—From the mother liquors of the hydrocarbon, m. $324-6^\circ$, obtained in the dehydration of sitosterol, there is isolated a 2nd hydrocarbon, sublimes at 11 mm. and $170-90^\circ$, and m. $246-8^\circ$; this is not identical with chrysene, m. $246-8.5^\circ$, obtained from cholesterol, since a mixt. of the 2 compds. begins to soften at 235° and is clear at 245° ; the tetra- NO_2 deriv., $C_{18}H_8N_4O_8$, light yellow, decomp. under 200° , while tetranitrochrysene, m. above 300° . A crystallographic comparison of chrysene and the new hydrocarbon also shows that they are not identical. Various other products were isolated and m. p. given, but no indication of compn. is offered.

C. J. WEST

The bile acids. XXVIII. The nature of the fourth ring. HEINRICH WIELAND and FRITZ VOCKE. *Z. physiol. Chem.* 177, 68–85 (1928).—The basal structure of the bile acids, disregarding substituent groupings, consists of 4 rings and a side chain, which may be tentatively arranged as follows

Rings I, II and III have already been definitely established. Ring IV is now believed to be pentacyclic, since the etiobilanic acid remaining after oxidative destruction of the side chain and rupture of the ring to which it is attached is a di-CO₂H acid which readily forms an anhydride. The exact location of the side chain (C₁₉ or C₁₈) and the placement of 3 additional carbons (3Me, Me + Et or Me₂CH) remain to be detd. There is reason to believe that the C to which the side chain is attached has no other substituent and that the adjacent C carries 2H. Further studies on the 4th ring now center upon the monocyclic tetra-CO₂H acid, C₁₆H₂₄O₈, remaining after oxidative destruction of rings I, II and III. Oxidation of this yields a tri-CO₂H acid, C₁₃H₂₀O₆, by destruction of the side chain at C₁₀. Attempts, however, to break the linkage between C₁₀ and C₁₁ were unsuccessful, although by this treatment 2 more C were removed. The formation of MeAc by oxidation of the C₁₆H₂₄O₈ acid with H₂O₂ was thought at first to indicate an Me₂CH group on Ring IV, but other compds. with sec. Me groupings, *e. g.*, β -methyladipic and α -methylglutaric acids, were found to react in the same way. Among the oxidation products of desoxycholic acid, an acid, C₇H₁₀O₆, was obtained, which had the m. p. 134° of *cis*- α -methyltricarballic acid but was not identical with it and split off CO₂ with formation of α -methylglutaric acid. The identity of the acid with methyl- β -carboxyethylmalonic acid was established by synthesis of the latter from MeCH-(CO₂Et)₂ and ICH₂CH₂CO₂Et. The Me group of this acid is best reconciled with the presence of a Me on C₁₁ of the bile acid skeleton. On account of the poor yields obtained in the conversion of the C₁₆H₂₄O₈ acid into its pyro acid (ketodicarboxylic acid, C₁₃H₂₀O₆), the acid esters were used in this reaction. The tri-Me ester, m. 100°, was prepd. by treatment of the acid with MeOH-HCl. The 4th CO₂H cannot be esterified in the usual way, this behavior suggesting the presence of 3 more C-linkages on the C carrying the CO₂H. This fact also supports the assumption of a Me on C₁₁. The tri-Et ester, m. 108°. Partial esterification of the free acid yields a di-Me ester, m. 167°. Sapon. of the tetra-Me ester prepd. by the use of CH₂N₂ yields a mono-Me ester, m. 163°, whereas sapon. of the tri-Me ester yields the free acid. When the tetra-Me ester is treated with N₂H₄·H₂O only 3 ester groups react, yielding a Me ester trihydrazide, m. 145° (decompn.). HNO₂ converts this into the azide, which on evapn. yields a urethan, and this in turn is sapond. to the tri-NH₂ acid HCl salt, m. 250° (decompn.). Attempts to remove the NH₂ groups by means of HOCl or HOBr were unsuccessful, the halogen substituting on the NH₂. The tri-CO₂H acid, C₁₃H₂₀O₆, obtained by further decompn. of the pyro acid from C₁₆H₂₄O₈ readily forms a tri-Me ester, but only 2 of these ester groups react with N₂H₄·H₂O. The product was converted *via* the azide and urethan into a diaminocarboxylic acid di-HCl salt, C₁₁H₂₂O₂N₂·2HCl, which decomp. 280°, but subsequent removal of the NH₂ groups was unsuccessful. In the prepn. of pyrodesoxybilanic acid by thermal decompn. of desoxybilanic acid an isomeric desoxybilanic acid, m. 221-2°, was obtained as a by-product. When heated to 250-60° this yielded the same pyro acid as the ordinary desoxybilanic acid.

A. W. Dox

The vapor density and some other properties of formic acid (COOLIDGE) 2. An x-ray examination of saturated dicarboxylic acids and of amides of the fatty series (HENDERSON) 2. Carbon dioxide cleavage from acetonedicarboxylic acid (WIGG) 2. Velocity of oxidation of alcohols by potassium permanganate (TRONOV, *et al.*) 2. Velocity of oxidation of alcohols by chromic anhydride and nitric acid in aqueous solutions (TRONOV, *et al.*) 2. Velocity of oxidation of the alcohols, ethers and esters by potassium permanganate and chromic anhydride under various conditions (TRONOV, LUKANIN) 2. Valency and refraction equivalents (AUWERS) 2.

Organic phosphorous compounds. H. T. BÖHME A.-G. Brit. 281,232, Nov. 25, 1926. Fats and oils are treated with P₂O₅ or acetylphosphoric acid or with mixts. of Ac₂O or AcCl and H₃PO₄ to obtain products for use in the textile, leather or pharmaceutical industries as *wetting agents* or *solvents* or *pharmaceutical agents*. Examples are given of the treatment of oleic and ricinoleic acid.

Organometallic compounds. MAY and BAKER. Fr. 632,834, Dec. 3, 1926. Basic Bi salts of arylarsonic acids are prepd. by treating a soln. of a Bi salt, especially of a hydroxypolybasic acid such as tartaric acid, with a soln. of an excess of arylarsonic acid. Examples are given of the prepn. of the basic Bi salts of *N*-phenylglycinamide-*p*-arsonic acid, *p*-aminobenzenearsonic acid, 3-acetyl-amino-4-hydroxybenzenearsonic acid, and 2-hydroxy-5-acetylaminobenzenearsonic acid.

Cyclic hydrocarbons. I. G. FARBERMID. A.-G. Brit. 281,298, Nov. 24, 1926. Hydrocarbons such as C₆H₆ and its homologs, C₁₀H₈, phenanthrene and C₁₁H₁₀ are

produced by treating aliphatic or hydroaromatic hydrocarbons with an excess of H or of a gas contg. H under pressure at temps. above 500° in a cyclic process, preferably with use of catalysts, and removing the gaseous hydrocarbons such as CH₄ to prevent accumulation of undesired products. Numerous details and examples are given.

Polymerization of olefins. FRITZ HOFMANN and MICHAEL OTTO. Fr. 632,768, Apr. 14, 1927. Hydrocarbons of the olefin series are polymerized by the action of BF₃ under pressure with or without finely divided metals.

Tetrazoles. GEORG SCHENING and BRUNO WALACH (to C. C. Boehringer Sohn). Can. 282,292, Aug. 7, 1928. Compds. contg. the group —C(:N—)OAc (acylated enolic form of a mono-substituted acid amide) such as those obtained from compds. of an oximic character by an intramolecular rearrangement (Beckmann), or by the enolization of mono-substituted acid amides, are allowed to act upon compds. contg. the N₃ radical, including hydrazoic acid.

Diazo compounds. SOC. ANON. POUR L'IND. CHIM. A BALE. Brit. 280,945, Nov. 18, 1926. The process described in Brit. 238,704 (C. A. 20, 1996), suitable for the manuf. of diazo preps. from naphthalenetrisulfonic acid, is used also for the production of diazo compds. in general, other than those derived from aminoazo compds. The diazo solns. may be evapd. with a neutral naphthalenetrisulfonate, with or without addition of a diluent or fixing agent such as NaCl, Na₂SO₄ or Al₂(SO₄)₃. The dried products dissolve in water with an acid reaction and may be mixed with an acid-binding agent such as a bicarbonate, borax or CaCO₃. Several examples are given.

Alkyl derivatives. ALBERT VERLEY. Fr. 632,124, Mar. 31, 1927. See Can. 279,590 (C. A. 22, 2754).

Separation of amines. SILESIA VEREIN CHEMISCHER FABRIKEN. Brit. 280,877, Nov. 19, 1926. A mixt. of mono- and dimethylaniline is dissolved in C₆H₆, phthalic anhydride is added and the mixt. shaken; the phthalamic acid is sepd. by use of dil. NaOH and is split into phthalic acid and monomethylaniline, dimethylaniline remaining in the C₆H₆. A similar procedure may be applied to the sepn. of other mono- and dialkylated aromatic amines.

Arsonic acid. ELMER B. VLIET and ERNEST H. VOLWILER (to The Abbott Laboratories). Can. 282,284, Aug. 7, 1928. A 3-amino-4- ω -hydroxyalkylaminobenzene-arsonic acid or deriv. is made by nitrating an ω -haloalkyl(*p*-arsonophenyl)carbamate, isolating the product of the reaction, converting the isolated product into 3-nitro-4- ω -hydroxyalkylaminobenzene-arsonic acid by treatment with an alkali, reducing the product to 3-amino-4- ω -hydroxyalkylaminobenzene-arsonic acid and then converting said acid to a salt by treatment with a basic substance.

Arylthioglycolic acids. I. G. FARBERIND. A.-G. Brit. 281,290, Nov. 24, 1926. Haloalkylbenzenes are treated with chlorosulfonic acid at temps. below 100° to produce *p*-halosulfonyl chlorides. These products may then be reduced to the corresponding mercaptans, which by condensation with chloroacetic acid yield thioglycolic acids. Examples are given of the production of the following, in which X = SO₂Cl, SH and SCH₂CO₂H: 2,4-MeClC₆H₃X from *m*-ClC₆H₄Me, 2,4,5-Cl₂MeC₆H₃X from 2,4-Cl₂C₆H₃Me, 2,4,3-Cl₂MeC₆H₃X from 2,6-Cl₂C₆H₃Me and 2,5,4-Me₃ClC₆H₃X from 1,4,2-Me₃ClC₆H₃. Zn dust and H₂SO₄ may be used for the reduction of the sulfonyl chlorides, and the thioglycolic acids subsequently produced by condensation may be isolated as such or as their Na or Ca salts.

Benzoic acid. DONALD L. TABERN (to the Abbott Laboratories). Can. 282,283, Aug. 7, 1928. *o*-O₂IC₆H₄CO₂H is prepd. by passing a halogen into an aq. soln. of a salt of *o*-IC₆H₄CO₂H, at a suitable temp., sufficient alkali being added to prevent the pptn. of the intermediate products, followed by pptn. of the O₂IC₆H₄CO₂H with a mineral acid.

Butyric acid. SOC. BREVETS ÉTRANGERS LEFRANC ET CIE. Fr. 633,446, Aug. 27, 1926. See Brit. 276,617 (C. A. 22, 2378).

Hydroxybenzoylbenzoic acid. I. GUBELMANN, H. J. WEILAND and O. STALLMANN (to Newport Co.). Brit. 281,227, Nov. 29, 1926. See U. S. 1,654,289 (C. A. 22, 788).

Lactic acid. W. KLAPPROTH. Brit. 280,969, Nov. 22, 1926. Lactic acid is purified by extn. with a solvent such as ether or a higher alc. in the presence of H₂SO₄ and Na₂SO₄ or other strong acid and a salt of the acid. The ext. is washed with a concd. soln. of a neutral or acid lactate such as that of Na, Ca or Ba and the lactic acid ext. is then freed from the ether which is reused. In some instances, further purification may be effected by heating with a small proportion of H₂SO₄ to 80–100°.

Sulfonic acids. I. G. FARBERIND. A.-G. Fr. 632,155, Apr. 5, 1927. See Brit. 272,967 (C. A. 22, 1848).

Acetic anhydride. H. DREYFUS. Brit. 280,972, May 26, 1926. HOAc vapor in

heated in the presence of H_2PO_4 , $\text{H}_4\text{P}_2\text{O}_7$ or HPO_3 or a mixt. of these, with or without pumice or kieselguhr at temps. of 100–400° and the reaction products are passed through fractionating columns to sep. Ac_2O . The crude product also may be distd. over dry NaOAc .

Hydroxycarboxylic acid chlorides. BRITISH SYNTHETICS, LTD., AND ERIC B. HIGGINS. Fr. 632,767, Apr. 14, 1927. *o*-Hydroxycarboxylic acid chlorides are prepd. by reaction of SOCl_2 on an inorg. salt of the acid in question; thus 2,3-hydroxynaphthoic acid chloride is produced from the Na hydroxynaphthoate.

Methanol. COMPAGNIE DE BÉTHUNE. Fr. 632,259, July 17, 1926. See Brit. 274,492 (C. A. 22, 2171).

Synthetic methanol. COMPAGNIE DE BÉTHUNE. Fr. 633,139, Aug. 6, 1926. See Brit. 275,600 (C. A. 22, 2171).

Pentaerythritol. HENRY A. AARONSON. U. S. 1,678,623, July 24. Acetaldehyde 44 parts and CH_2O about 150 parts are mixed with water not over 1000 parts, lime is gradually added with stirring until a temp. of 60° is attained, the addition of lime is further continued to maintain this temp. until about 33 parts are added, stirring at a temp. of 60–65° is continued for 2 hrs., the mixt. is cooled, the lime is pptd. with H_2SO_4 , the CaSO_4 is filtered out, remaining lime is removed with oxalic acid, the soln. is evapd. *in vacuo*, and the residue is washed, dried and pulverized.

Thymol and chlorothymol. F. RASCHIG. Fr. 633,067, Apr. 22, 1927. See Brit. 270,283 (C. A. 22, 1366).

Chloropyridine. DEUTSCHE GOLD- UND SILBER-SCHNEIDANSTALT VORM. ROESLER. Brit. 281,650, Dec. 3, 1926. 2-Chloropyridine is made by reaction of phosgene on *N*-alkyl-2-pyridones at an elevated temp.

Vanillin. JOSEPH TCHERNIAC. Fr. 632,640, April 11, 1927. See Brit. 268,158 (C. A. 22, 1164).

Catalytic hydrogenation of naphthostyryl, etc. I. G. FARBERIND. A.-G. Brit. 281,257, Nov. 25, 1926. Tetrahydronaphthostyryl or its homologs and substitution products are made by catalytic hydrogenation under pressure of naphthostyryl or a homolog or substitution product. Only the ring contg. the CO group is hydrogenated. Ni may be used as a catalyst.

Treating light paraffin hydrocarbons to obtain olefins, etc. ALEXANDER S. RAMAGE (to Bostaph Engineering Co.). U. S. 1,678,078, July 24. Material such as natural gas is heated to a temp. not substantially above 550° (suitably about 550°) with a reducible metal oxide such as Fe_2O_3 in order to form olefins which may be converted into alcs.

Calcium formaldehydesulfoxylate. I. G. FARBERIND. A.-G. Brit. 281,134, Feb. 14, 1927. A difficultly sol. Ca formaldehydesulfoxylate having 4 atoms of S to 3 atoms of Ca in the mol. is pptd. from an aq. soln. of Na formaldehydesulfoxylate by a mixt. of a sol. Ca salt such as CaCl_2 and Ca(OH)_2 or CaCO_3 .

Hydrogenating phenol-ketone condensation products. SCHERING-KAHLBAUM A.-G. (formerly Chem. Fabrik. auf Aktien vorm. E. Schering). Brit. 280,924, Nov. 16, 1926. The process as described in Brit. 276,010 (C. A. 22, 2379) is carried out at temps. substantially higher than usual hydrogenation temps., *e. g.*, the condensation product of *m*-cresol and acetone may be treated with H under pressure in the presence of a Ni catalyst at a temp. of 280° to form thymol and then stereoisomeric menthols (according to the duration of the treatment), or, the condensation product of *p*-cresol and acetone may be hydrogenated to form 4-methyl-6-isopropylphenol and then a mixt. of the stereoisomeric 4-methyl-6-isopropylcyclohexanols.

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

The enzymic cleavage of α - and β -glycerolphosphoric acids. P. KARRER AND R. FREULER. Univ. Zurich. *Festschrift A. Tschirch* 1926, 421–4; *Chem. Zentr.* 1927, I, 3064.—The behavior of α - and of β -glycerolphosphoric acid toward enzymes was compared. Glycerolphosphatase from the hepatopancreas juice of the vineyard snail was chosen for the enzyme, and the Na salts of synthetic racemic α - and β -glycerolphosphoric acid for the substratum. The best effect was in strongly acid soln., and both acids were hydrolyzed at the same rate by the enzyme. With sufficiently slow

action, the decompn. reaches 96%. When the results are recorded graphically, a similar course of the hydrolysis of each glycerolphosphoric acid is evident. An increase of the quantity of enzyme causes a relatively great cleavage in the early stages of the decompn. compared with that in the later stages.

C. C. DAVIS

Further results of research on pectin. H. ECKART AND A. V. GYALÖKAY. *Johs. Eckart Konservenfabr. Konserven-Ind.* 14, 2-3, 13-5, 37-40; *Chem. Zentr.* 1927, I, 1900-1.—The max. limit of gelation was at p_H 3.04-3.10 and the optimum p_H was 2.3. For 1% pectin, the lower limit of gelation was with a 50% addn. of sugar, the upper limit with 75% addn. and the optimum with 60% addn. The Ca pectate value is unsatisfactory as a criterion of the gelation effect.

C. C. DAVIS

The violet bands of blood serum. MORIKUNI SAITO. Kaiserlich. Univ., Kioto, Japan. *Acta Schol. Med. Univ., Kioto* 9, 303-6(1927).—Absorption bands were found in 20 samples of human serum in the violet at about 4100 Å. U. which were presumably not caused by hemoglobin since the violet bands were 16 times stronger than those in the yellow-green area. It is suggested that they may be caused by the colloidal condition of the serum.

H. J. DEUEL, JR.

The specificity of animal proteases. XII. The specificity of pancreatic trypsin and intestinal erepsin. ERNST WALDSCHMIDT-LEITZ, ANTON SCHAFFNER, HANS SCHLATTER AND WILLIBALD KLEIN. *Bayer Acad., Munich. Ber.* 61B, 299-306(1928); cf. *C. A.* 21, 1466, 3061; 22, 246.—The specificity of intestinal erepsin (I) and trypsin kinase (II) is influenced not only by the length of the peptide chain but by the constituent amino acids. Thus it was found the glycylglycine (1), leucylglycine (2), leucylleucine (3), glycylserine (4), alanylserine (5), leucinemethylisoserine (6), glycylcystine (7), dileucylcystine (8), leucylglutamic acid (9), [phenylalanyl]glutamic acid (10), glycyltyrosine (11), alanyltyrosine (12), diargininetritrate (13), alanyl [α -aminocaproic acid] (14), alanyl [β -aminobutyric acid] (15), leucyl [β -aminobutyric acid] (16), glycyl [α -aminocaproic acid] (17), and leucyl [ϵ -aminocaproic acid] (18) were hydrolyzed by intestinal erepsin (except 13) and not by trypsin-kinase (no expts. on 6, 14, 15, 16, 17, 18). Diarginine trinitrate is probably an anhydride since it does not hydrolyze with acid, which would explain the negative effect of the enzyme on it. The enzymes were able to hydrolyze the unnatural as well as the naturally occurring dipeptides. However, both I and II were inactive in causing a hydrolysis with a number of anhydrides (glycine anhydride, glycylalanine anhydride, alanine[phenylalanine] anhydride, glycylserine anhydride, and phenyldiketopiperazine). The lengthening of the C chain was without effect on changing the susceptibility to the individual enzyme. Thus leucyltriglycylleucine, leucylheptaglycine, leucylnonaglycine, and leucyltriglycylleucyltriglycylleucylnonaglycine were hydrolyzed by I but not by II while [α -bromoisocaproyl]nonaglycine and [α -bromoisocaproyl]triglycylleucylnonaglycine were not acted on by either enzyme. Leucylglycyltyrosine (19), glycylalanyltyrosine (20), glycyltyrosylglycine (21), glycylalanylglycyltyrosine (22) and leucyltriglycyltyrosine were hydrolyzed by II but only 19, 21 and 22 by I (no test on 20), β -naphthalenesulfonylglycyltyrosine was hydrolyzed by II and also by trypsin alone but at a slower rate. The splitting of a large no. of acylated peptides confirms the assumption of Euler and Josephson that for the union of a substrate to erepsin, the presence of a free NH_2 group is necessary while the change in the carboxyl group (by esterification or making an amide) is without effect on ereptic hydrolysis. The addn. of erepsin to the free NH_2 group probably is caused by a free aldehyde or ketone group of the enzyme. For the action of trypsin a free NH_2 group is unnecessary since the latter is active on β -naphthalenesulfonylglycyltyrosine. The attack of trypsin presumably is on the carboxyl group.

H. J. DEUEL, JR.

The isomerism of hemin and allo-hemin. RICHARD KUHN AND CARL SBYFFERT. Eidgenöss. Tech. Hochschule, Zurich. *Ber.* 61B, 307-14(1928).—A new isomer, allo-hemin, was prepd. from hemin by allowing acetic anhydride to act on acetic acid hemin in pyridine- $CHCl_3$ soln. at room temp. Its chief differences are in soly., being sol. in $CHCl_3$ and acetone and wholly insol. in 2 N NaOH at room temp. Both carboxyl groups of hemin are present in the allo isomer. On heating with soda soln. complete soln. of the allo-hemin occurs. Absorption bands of allo-hemin and hemin agree in dry and moist pyridine. By crystn. of allo-hemin from hot $CHCl_3$, or hot acetone, a compd. is obtained which is insol. in cold $CHCl_3$ and easily sol. in 2 N NaOH. Hemin \rightarrow Allo-hemin \rightleftharpoons hemin. Allo-hemin when dried at 110° in vacuum and pulverized is easily sol. in $CHCl_3$ after 6 months. Acetic anhydride plays the important role in the change of hemin to allo-hemin, the pyridine and $CHCl_3$ acting only as solvents.

H. J. DEUEL, JR.

Remarks on the work of E. Waldschmidt-Leitz and W. Klein—on the specificity

and method of action of erepsin, trypsin and trypsin-kinase—as well as that of E. Waldeschmidt-Leitz and Gertrud Rauchsches—on the specificity of peptidases. II. Comparison of the peptide-sugar combination with the method of action of erepsin. KARL JOSEPHSON. Univ. Stockholm. *Ber.* 61B, 1276-9(1928).—Cf. C. A. 21, 2381. Polemical. H. J. DEUHL, JR.

The action of the pepsin of herbivora and carnivora on vegetable and animal proteins. H. W. VAHLTEICH. *Z. physiol. Chem.* 176, 222-30(1928).—Pepsin was prepd. from horse stomach and from dog stomach by the same method and the action of each prepn. on the vegetable proteins, edestin, gliadin and glutenin, and on the animal protein, myosin, detd. by the Willstätter and the Van Slyke methods. The 2 pepsins were apparently identical, the extent of digestion of a given protein being approx. the same in both cases. The Willstätter method gave in all cases higher values for amino N than the Van Slyke method. A. W. DOX

Bacterial catalase. ARAO ITANO AND SATIYO ARAKAWA. *Ber. Ohara Inst. landw. Forsch.* 3, 505-28(1928); cf. C. A. 22, 2382.—The catalase was obtained from *Clostridium thermocellum* and a thermophilic cellulose-fermenting bacterium isolated by Itano. The catalase action was influenced by the H-ion concn., a $p_H < 7$ having a stronger depressive action than $p_H > 7$. The action in glucose broth was not influenced appreciably by the quality or quantity of glucose used. Cultures 72 hrs. old gave max. catalase action; older cultures showed lowered activity. The velocity of the action decreased upon standing. Such chemicals as $MgSO_4$, $CuSO_4$, HCl , $HgCl_2$ and KCN depressed the action of catalase, KCN being the strongest depressor. Many tables and curves are given. RUSSELL C. ERB

Chemical and enzymic processes in the light of stereochemical research. CARL NEUBERG AND MARIA KOBEL. *Naturwissenschaften* 16, 392-6(1928).—A review with 19 references. B. J. C. VAN DER HOEVEN

The character of the action of enzymes on proteins and polypeptides. EMIL ABDERHALDEN. *Naturwissenschaften* 16, 396-9(1928).—A review. B. J. C. v. d. H.

Acid binding and swelling of fibrin. I. ERWIN VOIT. *Z. Biol.* 87, 270-8(1928).—Sol. albumin hydrolyzes slightly in acid but undergoes strong electrolytic dissocn. Fibrin, however, shows relatively great hydrolysis and little dissocn. There is greater association between acid and native fibrin than between acid and denatured fibrin. II. Swelling of native fibrin in dilute hydrochloric acid. FRITZ SCHULDENZUCKER. *Ibid* 279-91.—Fibrin can bind acid and then undergo marked hydrolysis. This is associated with marked swelling (9 times more than neutral fibrin). III. Water and acid binding of fibrin coagulated by boiling water. FRIEDRICH LOCHMÜLLER. *Ibid* 292-306.—When fibrin is purified with hot water, alc. and ether, it loses its fat and practically all its ash. Boiling with water causes the soln. of an albumin substance (the loss = 16.05% N). For horse fibrin the figure is 12% and for ox 7%. Denatured fibrin does not lose its acid-binding power but the acid-binding power increases less slowly with increase in acid concn. As in the case of native fibrin, there is slight soln. after treatment with acid; for native fibrin this dissocn. is 6.7%, for denatured 3%. FRANCES KRASNOW

Dehydration of malic acid. I. AMANDUS HAHN AND W. HAARMANN. *Z. Biol.* 87, 465-71(1928).—Frog muscle contains a large amt., of malic acid dehydrase, which seemed to be more active in the spring months than in the winter months. When this enzyme acts on malic acid large quantities of CO_2 are liberated. FRANCES KRASNOW

The photodynamic action of hematoporphyrin. ETHELBERTA N. ROCK AND W. H. HOWELL. Johns Hopkins. *Am. J. Physiol.* 84, 363-77(1928).—The fatal effects of light on animals that had received injections of hematoporphyrin were generally the same in all species tested; cutaneous irritation with great motor excitation, erythema and edema of the skin and hyperpnea, followed by cutaneous cyanosis, loss of sensibility, stupor and death. The toxic action is localized and toxic substances are not carried in the blood. Blood pressure, after some fluctuations, slowly sank to a lethal level, due probably to paralysis of the cutaneous circulation. Possibly the hematoporphyrin combines slowly with a substance or substances in the tissues. Light acting on this compd. gives rise to the injurious effects. J. F. LYMAN

Changes in permeability associated with the absolute minimum vital temperature. NELLIE M. PAYNE. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 81, 504(1927).—In insects at the lowest temp. at which they can live changes in cell permeability occurred,

the cell wall becoming permeable to protein. This change was followed by rapid oxidation. J. F. LYMAN

The effect of changes of hydrogen-ion concentration on the cardiac action current. JANE SANDS AND WILLIAM AMBERSON. Woman's Med. Coll. of Penn. and Univ. Penn. *Am. J. Physiol.* **84**, 533-44(1928).—Pulse rate, conduction rate and action currents varied according to the acidity of the soln. bathing the heart. J. F. LYMAN

Penetration of ultra-violet rays through clothing materials. CARRIE C. DOZIER AND HARRIET MORGAN. Utah Agr. Expt. Sta. *Am. J. Physiol.* **84**, 603-9(1928).—Ultra-violet did not penetrate baby flannel, pongee and crepe de chine sufficiently appreciably to activate cottonseed oil in respect to vitamin D. Artificial silk and meadow lane materials transmitted the rays. J. F. LYMAN

Phosphagen. PHILIP EGGLETON AND GRACE PALMER EGGLETON. Univ. Coll., London. *J. Physiol.* **65**, 15-24(1928); cf. *C. A.* **22**, 454.—Phosphagen (an ester of H_2PO_4 and creatine) occurs in resting voluntary muscles of all vertebrates. It is readily hydrolyzed in acid medium and hence must be extd. rapidly. It does not give the diacetyl color reaction for creatine. Muscles capable of rapid energy output are, in the resting condition, richer in phosphagen than those intended for lower rates of energy expenditure. Under anaerobic conditions and in resting muscle the disappearance of phosphagen was not correlated with lactic acid production. The breakdown of phosphagen always resulted in the liberation of a proportional amt. of creatine. Resynthesis of phosphagen in a fatigued muscle was very rapid if the surrounding atm. was rich in O_2 . When phosphagen broke down in resting muscles under anaerobic conditions the P remained entirely as inorganic phosphate; phosphagen destroyed as a result of activity produced inorganic phosphate and organic phosphate esters; phosphagen destroyed during incubation with NaF in a soln. buffered with $NaHCO_3$ was accounted for entirely by the phosphate esters formed. The phosphate ester produced in fatigue is identical with Embden's lactacidogen. J. F. LYMAN

The enzymic processes in mammalian skeletal muscle. MYRA K. BEATTIE, J. BELL AND T. H. MILROY. Queens Coll., Belfast. *J. Physiol.* **65**, 109-45(1928).—Muscle juice, obtained by pressing minced muscle, or exts. of muscle prepared by Myerhoff's method, incubated at 22° to 45° gave an approx. equimol. production of H_2PO_4 and lactic acid from the breakdown of the hexose diphosphate present. When glycogen alone was added esterification and lactic acid production occurred in approx. equimol. proportions at 22°, while the inorganic phosphate decreased. At 37° both esterification and lactic acid production were diminished, but the equimol. proportions were maintained. At 45° esterification ceased but diastatic action and the breakdown of pre-existing hexose diphosphate continued. When both glycogen and phosphate were added esterification became the dominant process at 22°. At 37° esterification was less and lactic acid production was greater than at the lower temp. At 45° there was some esterification along with lactic acid production; while at 50° both processes were inhibited although diastatic action was evident. In the presence of NaF esterification alone occurred and always to a greater extent than in its absence. Esterification of itself, owing to the formation of esters with higher dissociation consts. than H_2PO_4 , resulted in a fall of buffering capacity in the neighborhood of the neutral point and a rise in the more acid zone of p_H 6.5 to 5.5. J. F. LYMAN

The action of substances containing the alcoholic hydroxyl groups on pancreatic lipase. A DI FRISCO. *Boll. soc. ital. biol. sper.* **3**, 299-303(1928).—The hypothesis is advanced that the protective action of glycerol and glucose on pancreatic lipase is due to the presence of OH groups which combine with the metallic catalyzer in the enzyme and prevent its flocculation. Expts. were made to det. whether Na K tartrate and Na citrate have a similar protective action. Fresh and heat-inactivated pancreatic juice were added to samples of oil of sweet almond contg. (a) glycerol, (b) tartrate and (c) citrate. Pancreatic juice + glycerol, pancreatic juice + tartrate, and pancreatic juice + citrate were inactivated by heat and each was added to sweet almond oil. The addn. of glycerol, tartrate and citrate to inactivated juice restored partly the hydrolytic action. Juice in the presence of tartrate, citrate and glycerol resisted heat inactivation. Glycerol and tartrate increased somewhat the hydrolytic action of fresh juice; citrate inhibited it slightly. Tartrate and citrate have, therefore, a protective action on pancreatic lipase similar to that of glycerol. PETER MASUCCI

The radiation risks of the röntgenologist. A. E. BARCLAY AND SYDNEY COX. *Am. J. Roentgenology and Radium Therapy* **19**, 551-61(1928).—Measurements were made of the amts. of radiation received by various workers in the course of routine x-ray therapy, fluoroscopy, and radiography. On the basis of these measurements, a daily exposure of 0.00028 of a unit skin dose is recommended as the safe limit. De-

tails as to the amt. of protection necessary for different types of x-ray work are given.

E. H. QUIMBY

A note on the viscosity changes produced in egg albumin by x-rays. J. A. V. FAIRBROTHER. *Brit. J. Radiology*, [N. S.] 1, 121-5(1928).—The viscosity of egg albumin is decreased to a min. value, sometimes as much as 40%, by an x-ray dose of about 211,500 e, from a beam of Mo K radiation. This decrease is permanent and no appreciable subsequent coagulation occurs. When irradiated egg albumin is brought to the coagulation temp., 61°, setting is delayed.

E. H. QUIMBY

The intensity of radiation in the vicinity of filtered radon implants. EDITH H. QUIMBY. Memorial Hosp., N. Y. City. *Radiology* 10, 365-76(1928).—The distribution of the intensity of radiation about a tube of radon inserted in organic material has been investigated by the production of 3 phenomena, tissue necrosis, bleaching of butter, erythema of human skin. The actual intensities necessary to produce these were quite different, but the relative intensities for different distances from the tube were the same. A curve was derived representing the variation of intensity or quantity of radiation with distance from the buried source. Possible applications of this information to Ra therapy are discussed.

E. H. QUIMBY

The transport numbers of fibrin in solutions of dilute acids and alkalis. DAVID M. GREENBERG. Univ. of Calif. *J. Biol. Chem.* 78, 265-80(1928).—The transport no. of fibrin was detd. in soln. in NaOH, KOH, LiOH and in HCl, HBr and HNO₃. The same value was obtained in all solns. The sum of the transport nos. of anion and cation was approx. unity. The mobility of the fibrin as cation was calcd. to be 78, and as anion 44. In solns. in weak acids the values for the transport nos. were higher than would be expected if independent migration were taking place. This indicates formation of complex ions.

C. RIEGEL

The alleged conversion of fat to carbohydrate. I. The metabolism of acetic acid. HARRY J. DEUEL, JR. AND ADOLPH T. MILHORAT. Cornell Univ. *J. Biol. Chem.* 78, 299-309(1928).—Na acetate administered to phlorrhizinated dogs caused no significant change in D:N ratio. This indicates acetic acid is not a glucogenic substance. Only a small amt. of acetate was excreted, suggesting practically complete oxidation in the animal.

C. RIEGEL

Distribution in the organism of oil injected into the arterial system. Proof of pulmonary lipopexia. LÉON BINET AND RENÉ FAHRE. *Compt. rend. soc. biol.* 99, 190-2(1928).—Emulsified olive oil rendered fluorescent by the addn. of diphenylanthracene was injected into the arterial system and the fat extd. from different organs was examd. by the Wood radiations. The fat-fixing power of the lung was particularly marked, that of the muscle, liver and kidney following in order.

L. W. RIGGS

Physico-chemistry of the vitreous body. Relation of p_H to its swelling. F. REDSLOB AND P. REISS. *Compt. rend. soc. biol.* 99, 219-22(1928).—A special app. designed for this study is illustrated and described. The curve of swelling of the vitreous body shows a characteristic course as a function of the p_H . The p_H of freshly enucleated vitreous body 1 hr. after death was 7.7. By injections of isotonic solns. the zone of p_H ranging from 7.8 to 8.8 was explored and max. of swelling were observed, at 8.1 and 8.7, and a min. at 8.25. The relatively high p_H is explained by the spontaneous *post-mortem* evolution of the vitreous body toward alkali.

L. W. RIGGS

Ultra-violet irradiation and elaboration of the heterohemolysins. A. BESSEMAN AND P. NELIS. *Compt. rend. soc. biol.* 99, 329-31(1928).—The results generally indicated that the irradiation employed had little or no influence on the titer of natural heterohemolysins, or on the elaboration of artificial heterohemolysins in the rabbit.

L. W. RIGGS

The phosphorus of serum. M. MACHEBOEUR. *Ann. Inst. Pasteur* 41, 1036-44; cf. *C. A.* 21, 2005, 3642.—The results obtained confirm those of Greenwald in his isolation of a diphosphoglyceric acid from pig blood. In addn., it is claimed that a stable phosphoric ester is present in serum and also that one part of the H₃PO₄ is bound with glyceric acid forming a stable compd. which is rather resistant to acid hydrolysis.

B—METHODS AND APPARATUS

STANLEY R. BENEDICT

A method for the biological assay of cod-liver oil. GEORGIAN ADAMS AND E. V. MCCOLLUM. Johns Hopkins Univ. *J. Biol. Chem.* 78, 495-524 (1928).—An attempt to obtain standardized procedure for this assay. The diet used for the test was the McCollum diet 3143 although the McCollum diet 4338 or Steenbock's diet 2965 were satisfactory while the McCollum diet 4025 did not produce rickets. Rats weighing 50-60 g. were used and were kept in a darkened room to prevent the complication of ultra-violet radiation. Control animals were killed before the cod-liver oil was given in a dose of 0.125 or 0.25% for 8 days; then the rachitic rats and a second set of control animals were killed. The serum Ca remains at the normal level of 10-11 mg. but P falls after the rachitic diet from 8.5 mg. to lower levels (4.5, 1.54, 2.01 mg.) in various groups after 21 days. The $[Ca^{++}] \times [PO_4^{--}]$ product is always below 8.0×10^{-23} in active rickets while it increases above this value in healing. The results of the analyses of the ash of the femurs after different lengths on the rickets-producing diet usually showed a decrease but showed great variation. However, when rats of a single sex (male) were used there was a more nearly graded falling off in the ash (29.17% at 21 days, 28.32% at 28 days, 29.60% at 29 days, 25.92% at 37 days and 24.64% at 40 days) using the average of 3 to 7 rats. However, the individual variations were considerable. There is also no particular relationship between the strength of the line test and the ash content. Similar deviations were found in the Ca and P values in the bones. The right and left femora of the same animal showed considerable deviations in Ca content although the P was fairly uniform. This agrees with the observation that the line test may vary in the two bones. The requirements set forth for the test are (1) a basal diet which allows fairly rapid growth of animals, (2) having a condition of florid rickets in 18-21 days and (3) allowing a healing in 8 days when cod-liver oil is given in a dose of 0.125 g. or higher. Antirachitic potency cannot be detd. by changes in bone compn. Blood analyses giving the $[Ca^{++}].[PO_4^{--}]$ values indicate whether the animal has active or healing rickets and can be correlated with the line test when averages of 10 to 15 animals are used. Variations in the vitamin D content of cod-liver oils were found.

H. J. DEUEL, JR.

Determination of urea in blood. F. W. Fox. *Biochem. J.* 22, 545-7 (1928).—The method is based on a procedure described by Kennaway (cf. *C. A.* 14, 3432). For macro-extn., the method is as follows: measure 5 cc. blood into 175 cc. conical flask, followed by 5 cc. 0.75 N H_2SO_4 and 5 cc. of 10% Na tungstate. Add 35 cc. water, shake and filter into a 50 cc. measuring cylinder. Place 30 cc. filtrate into another 175 cc. conical flask and wash out the cylinder with 10 cc. water. Add 3 drops 0.2% methyl red or chlorophenol red, boil and cool under tap. (Run blank with each batch of estns. Place 40 cc. water in a similar flask with equal quantity of indicator. Adjust to reddish yellow color with 0.01 N acid or alkali.) Now neutralize the test, first approx. with 0.1 N alkali and finally match with the blank with 0.01 N alkali. Add 5 cc. enzyme ext. (made by shaking 1 g. powd. soy bean with 50 cc. 0.85% saline and filtering after 20 min.) to both blank and test. Incubate for 1 hr. at 50°. Add 0.01 N acid until soln. is acid. (Most samples require about 10 cc.) The blank receives 10 cc. Boil, cool under tap and titrate with 0.01 N alkali, matching the test against the blank. The difference between vol. of alkali used for the test and that used for the blank when multiplied by 10 gives percentage urea in blood. A micro-estn. is also described. B. H.

What is the value of the cholesterol determination in the case of lead poisoning? ERNST KÜHN. *Zentr. Gewerbehyg. Unfallverhüt* 14, 117-29; *Chem. Zentr.* 1927, 11, 602.—The cholesterol content of the blood is generally taken as a measure of the ability of the organism to protect itself. In the case of lead poisoning the cholesterol content of the whole blood is frequently higher than the cholesterol content of the serum. Under normal circumstances the reverse is true. This phenomenon cannot yet be considered as specific of Pb poisoning. A. L. HENNE

The nature of the van den Bergh reaction. W. M. ROBERTS. *Brit. J. Exptl. Path.* 9, 107-12(1928).—The pigment of hemolytic serums gives a direct reaction if extd. by CHCl_3 and dissolved in an alk. buffered soln. This is in opposition to the hypothesis of Davies and Dodd (cf. *C. A.* 22, 605) that the pigment of hemolytic serums is present as an oxidation product of bilirubin. It is probable that bilirubin in such serums is present largely in the free colloidal condition. The suggestion of Collinson and Fowweather (cf. *C. A.* 22, 2403) that in those serums giving the direct reaction the bilirubin is present as the NH_4 salt is shown to be untenable. It appears that the bilirubin is in combination with some substance, the nature of which is as yet undetd., this combination being destroyed by the addn. of alc., leaving the bilirubin as a salt—probably the Na salt. HARRIET F. HOLMES

Bilirubin and the van den Bergh reaction. C. E. NEWMAN. *Brit. J. Exptl. Path.* 9, 112-9(1928).—The different van den Bergh reactions probably are due to an underlying chem. difference between the bilirubins. The behavior of azobilirubin as a dichromic indicator and the many differences between the bilirubins from different sources all point to its being, as pure bilirubin, an org. acid contg. 2 COOH groups and capable of forming 2 series of salts. The differences between pure bilirubin, the acid, and the delayed reaction pigment seem to indicate that the latter is a substance closely allied to the former, but considerably more stable. Pure bilirubin could not circulate as such in the blood, since it is changed on soln. in serum to the prompt reaction type of pigment. Prompt-reaction bilirubin is probably Na H bilirubinate. The disodium salt exists only in extreme alk., and does not concern physiology or pathology. The delayed reaction pigment cannot be biliverdin, because this substance is green, insol. in CHCl_3 , and only gives the van den Bergh reaction in 12-24 hrs.—all points of distinction from the delayed-reaction pigment. HARRIET F. HOLMES

The auto-inhalation method of anesthesia in canine surgery. JOHN C. HARDEN-BERGH AND FRANK C. MANN. *J. Am. Vet. Med. Assoc.* 71, 493-501(1927).—A cabinet inhalation method is described. It is very advantageous. An even anesthesia may be maintained over a long period, and hence furnishes a feasible one-man method that can be employed in emergencies by the practitioner. FRANCES KRASNOW

Iron metabolism. IV. WOLFGANG LINTZEL. *Z. Biol.* 87, 157-66(1928); cf. *C. A.* 22, 3435.—The Neumann-Hanslian method is not applicable to Fe detn. in urine. With the method of Lach and Friedenthal no Fe is found in normal urine. A new colorimeter technic for the detn. of Fe is described. Fe is sepd. as ferriphosphate and ferrosulfite from other salts obtained in urine ash and measured as the thiocyanate. Normal urine is free from Fe. FRANCES KRASNOW

Delay of blood in passing through the lungs as an obstacle to the determination of the carbon dioxide tension of the mixed venous blood. W. F. HAMILTON, J. W. MOORE AND J. M. KINSMAN. Univ. Louisville, Ky. *Am. J. Physiol.* 82, 656-64(1927).—The difference between CO_2 tension of alveolar air and rebreathed air increased significantly as the rebreathing time increased. This is thought to arise from the fact that at the beginning of rebreathing the lungs are full of arterIALIZED blood and as this blood leaves the lungs and venous blood enters, the tension of the rebreathed air gradually rises as the mean tension of the blood in the lungs rises. The accuracy of detg. circulation rate from the difference of CO_2 in alveolar and in rebreathed air is questioned. J. F. LYMAN

The efficiency of bicarbonate and phosphate buffers for experimentation with excised organs. TORALD SOLLMANN, W. F. VON OETTINGEN AND Y. ISHIKAWA. Western Reserve Univ. *Am. J. Physiol.* 85, 118-28(1928).—If a definite p_H is essential in physiol. expts. where the buffer soln. is being aerated it is recommended to maintain it by the periodic addn. of bicarbonate (or HCl) under colorimetric control. J. F. L.

Precipitins obtained by means of proteins coagulated by alcohol and their specificity. E. NICOLAS AND K. KATRANJIEFF. *Compt. rend. soc. biol.* 99, 184-6(1928).—Antiserums obtained by means of proteins of blood serum coagulated by alc. may be used for zoölogic differentiation of proteins. This may be applied in food exams. in *distinguishing beef and pork*. L. W. ROOS

Purification of pepsin. I. A quantitative method for the determination of pepsin.

II. Purification of pepsin by adsorption and the composition of purified pepsin. THOMAS LEROY McMEEKIN. *Abstracts of Theses, Univ. Chicago, Science Series* 4, 391-6 (1925-6) (publ. May, 1928).—For estg. its digestive activity, 1:4000 U. S. P. pepsin in a concn. of 0.1 to 10.0 mg. were allowed to act for 2 hrs. and at a temp. of 40° on 4-g. coagulated egg white suspended in 100 cc. 0.3% HCl. The egg white has to be prepd. by a special process. Then the soln. was filtered, the total N detd. by the method of Koch and McMeekin (cf. *C. A.* 18, 3335), and in another portion, the refractive index was taken. Both procedures furnished corresponding values of the rate of hydrolysis, yet the latter method is to be preferred. In studying the adsorption of pepsin on egg white, the H-ion concn. was found to have a great influence on the amt. of pepsin adsorbed. Adsorption occurs at any p_{H} between 1 and 7, but the adsorption is greatest at a p_{H} of 3.0. In 100 cc. soln. of p_{H} 3.0, and contg. 1000 mg. pepsin, 90% of the latter were adsorbed by 4-g. egg white. The pepsin adsorbed can be removed by $NaHCO_3$ or Na_2HPO_4 solns. With $NaHCO_3$, the max. release of 66% was obtained at a p_{H} of 3.0, while Na_2HPO_4 was most efficient (96%) at p_{H} 6.1 to 6.2. Based on these findings, a method of purification of com. pepsin is devised. Pepsin thus prepd. had a high activity (1:52-000) it gave the biuret, xantho-proteic and diazo reactions. The N content was 12.8 to 13.8%. It contained small amts. of P and reducing substances. G. SCHWOCH

Turbidimetric methods for sugar in blood and urine. ANTON R. ROSE. *J. Lab. Clin. Med.* 13, 382 (1928).—Clarify by shaking the sample with a modified Lloyd's reagent, add 3 cc. of ferricyanide reagent to 1 cc. of the filtrate; digest for 15 min. in boiling H_2O , dil. with H_2O to the 20-cc mark, mix; to 1 cc. of this dil. mixt. add 13 cc. of NH_4 soln. and treat with 1 cc. M $ZnSO_4$ soln.; measure the resulting turbidity in the Euton Junior (or wedge) Scopometer. This method is credited with the advantage of working over both normal and pathologic ranges of sugar in urine. On application of this method to blood the results have been more like Folin's Cu method than Benedict's picric acid method. ETHEL W. WICKWIRE

Lamotte-Wuth bromide comparator. W. A. TAYLOR. *J. Lab. Clin. Med.* 13, 495 (1928).—A method is given for the detn. of the bromide content of blood serum. ETHEL W. WICKWIRE

C BACTERIOLOGY

CHARLES B. MORREY

The mechanism of the degradation of fatty acids by mold fungi. II. PHILIP D. COPPOCK, VIRA SUBRAMANIAM AND THOMAS K. WALKER. *Univ. Manchester. J. Chem. Soc.* 1928, 1422-7; cf. *C. A.* 21, 2394.—*Aspergillus niger* grew satisfactorily on Ca butyrate, producing the following changes: Ca butyrate \rightarrow butyric acid \rightarrow β -hydroxybutyric acid \rightarrow acetoacetic acid \rightarrow acetone. No crotonic acid was formed and it was proved that *A. niger* would not grow on the salts of this acid as the sole source of C. On a medium contg. Ca valerate as the sole source of C, *A. niger* grew satisfactorily, giving a mixt. of β -hydroxy valeric acid and $\begin{matrix} CH_3 \\ C_2H_5 \end{matrix} \rangle CO$ but which

of these was formed first was not detd. On isovaleric acid*acetone was formed after 6 days by *A. niger* by the loss of a methyl group and the production of CH_3COCH_2COOH . H. J. DEUEL, JR.

Raising fermentative activity of *B. venturellii*. AMBROGIO DE TOMASI. *Boll. ist. sieroter. Milan* 5, 216-8 (1926). *Biol. Abstracts* 1, 677.—*Bacillus venturellii* in milk was accustomed to acetone and Am alc. by adding increasing amts. of these substances. The organisms so treated when cultivated on potato mash produced increased yields of distillable substances, about 50% more than organisms not so "exalted" in fermentative power. H. G.

The conditions of growth of the Bordet-Gengou bacillus. T. HAKAYAWA AND S. INAMORI. *J. Orient. Med.* 7, 105-26 (1927); *Ber. ges. Physiol. exptl. Pharmacol.* 44, 579.—Shiga's glycerol-potato-broth agar with horse serum (7.3) is the most favorable medium for culture and isolation from the sputum. Fresh potato promotes growth; fresh blood is not indispensable. The optimal p_{H} is 6.8-8.0 for the *Bacillus Gengou*, 6.6-8.0 for the *Bacillus influenzae*. The limits of viability are: 3.6-9 and 4.4-9, resp. A sepn. with the aid of the p_{H} was, therefore, impossible. MARY JACOBSEN

A simplified method for detecting indole formation by bacteria. NIKOLAUS KOVACS. *Staatlichen Serotherapeutischen Institut. Z. Immunitäts.* 55, 311-5 (1928).—The soln. used was p -dimethylaminobenzaldehyde 5 g., amyl alc. 75 cc., concd. HCl 25 cc. The principle of the test is that when the culture in bouillon is shaken with the

soln. indole is extd by the amyl alc. and reacts in a medium where the color is not changed by the color of the bouillon.

JULIAN H. LEWIS

Lactic acid production by scarlet fever streptococci and the common pyogenic streptococci. A. KAPPUS. Univ. Berlin. *Z. Hyg. u. Infektionskrankh.* 107, 697-701 (1927).—There is no difference in the character of the lactic acid produced by the true streptococci of scarlet fever, the ordinary streptococci from the mouths of scarlet fever patients, and the common pyogenic streptococci. Formation of *d*-lactic acid is the rule. Racemic lactic acid and *l*-lactic acid are usually produced, but only in small amount. The quantity formed seems to depend primarily upon the time of incubation. That formed in the early stages seems to be destroyed in more prolonged incubation. The quantity formed is of no differential diagnostic value for distinguishing the various types of streptococci here considered.

E. R. LONG

Adsorption and disinfection. I. Investigation with mercury and silver salts. GEORG LOCKEMANN AND HERMANN PILCHER. Robert Koch Inst., Berlin. *Z. Hyg. Infektionskrankh.* 108, 125-45 (1928).—The nature of the material in which bacteria are present is of the first importance in disinfection. Wool absorbs Hg solns. most strongly. Silk, cotton and linen are less absorbing. Absorption of Ag salts is similar except that in the presence of dil. solns. (0.17%) silk at first surpasses wool, 24 hrs. being required to equalize the effect. In the presence of wool the disinfecting power of solns of HgCl₂ and AgNO₃ for paratyphoid B and colon bacilli and *Staphylococcus aureus* is low. In the presence of silk the disinfecting power is somewhat higher. Cotton and linen interfere still less with disinfection.

E. R. LONG

Observations on the formation of diphtheria toxin. A. GALLINCK. Univ. Berlin. *Z. Hyg. Infektionskrankh.* 108, 522-9 (1928).—The addn. of 0.2% sugar to the medium of growth of diphtheria bacilli leads to marked acid production and inhibits diphtheria toxin production. Aeration of such a culture does not increase the toxin production. Correction of the H-ion concn. during growth is without influence on toxin formation. In an irregular manner, varying with the strain of bacillus used, the addn. of cystine leads to higher and more rapid production of toxin, and even to toxin formation by strains not ordinarily forming toxin.

E. R. LONG

Special synthetic media for the cultivation of bacteriophage. S. RACCHISA. *Boll. soc. ital. biol. sper.* 3, 257-8 (1928).—Two formulas are given for making synthetic media suitable for the cultivation of bacteriophage. (1) asparagine 3 g., NaCl 4.50 g., MgSO₄ 2 g., K₂HPO₄ 2 g., H₂O, 1000 cc. (2) glycine 1 g., MgSO₄ 2 g., NaCl 2 g., K₂HPO₄ 2 g., NH₄ lactate 3 g., H₂O, 1000 cc. Dissolve the substance in H₂O, boil, neutralize and autoclave. Filter, place in tubes and sterilize in autoclave.

P. M.

Direct microscopic observations on the growth of the colon bacillus. The periodicity of bacteriophage action. K. A. JENSEN. State Serum Inst., Copenhagen. *Centr. Bakt. Parasitenk. I Abt.* 107, 1-34 (1928).—At certain stages of growth the bacilli have little protoplasmic material and are resistant to lysis.

JOHN T. MYERS

Food utilization by the colon bacillus. H. BRAUN, H. LISCH, H. HENKEL AND P. GINTSCHOFF. Univ. Frankfurt. *Centr. Bakt. Parasitenk. I Abt.* 107, 35-48 (1928). The colon bacillus can utilize only a few org. acids of the aliphatic series. It can use lactic, succinic and malic acids, and many carbohydrates. The intestinal disturbances due to eating unripe fruit may be due to fermentation of malic acid and carbohydrates. Shiga-Kruse dysentery bacilli have a narrower food range than does *B. coli*.

J. T. M.

A contribution to the knowledge of antagonism of the typhoid and the colon bacillus, and the use of enriching media for the typhoid bacillus. J. VIGNATI. Univ. Brun. *Centr. Bakt. Parasitenk. I Abt.* 107, 54-69 (1928). By nephelometric observation it was possible to note that some substances had a stronger effect on the protoplasm of the colon bacillus than of the typhoid bacillus. Victoria blue showed the most marked distinctions, but they were too slight to be of practical value, since the proteins are so similar. Cultures of the colon bacillus produce a filterable substance which hinders the multiplication of the typhoid bacillus. Adsorbents like bolus alba will remove this substance, but its presence in the medium will not prevent over growth by *B. coli*. Apparently the inhibitory agent has a greater affinity for the typhoid bacillus than for the adsorbent. Cultures in bile plus lactic acid did not overcome the inhibitory agent. NH₄OH in bile favored the typhoid bacillus and Na₂CO₃ was better still. This is not a direct chem. inhibition of *B. coli* but a change in biol. relationships between *B. coli* and *B. typhosus*. Na₂CO₃ bile (14 cc. of 1% Na₂CO₃ plus 100 cc. of bile) is a practical enriching medium for typhoid in feces. Further work is in progress.

J. T. M.

A fatal case of meningitis caused by a capsulated bacillus. H. KLEWEL. Univ. Heidelberg. *Centr. Bakt. Parasitenk. I Abt.* 107, 100-4 (1928).—The organism differed

from Friedländer and other capsulated bacilli in its ability to liquefy gelatin and the formation of an amber pigment.

JOHN T. MYERS

Effects of dyes in bacteria. I. FR SARTORIUS Westphal Kaiser Wilhelm Univ., Munster. *Centr. Bakt. Parasitenk. I. Abt.* 107, 134-56(1928); cf. *C. A.* 21, 113.—The effect of many dyes in the presence of many salts on the members of the colon-typhoid group of bacteria was studied. Methylene yellow H favors the paratyphoid bacilli and inhibits coli and typhosus. Resorcinol black was the most favorable dye found as a selective agent for *B. typhosus*, young cultures being more resistant than old ones. Dahlia favors the pathogens at the expense of the colon group if the p_H is between 8.0 and 8.5. Work is in progress as to any relationship between dye resistance and virulence. Here is a good bibliography. II. **The action of dyes of different constitution at different p_H values.** *Ibid.* 398-427.—The action of the azine dyes on the colon group seems directly proportional to the no. of amino groups, which give them their basic character. It may be modified by the type of substitution in the amino groups. The introduction of alkyl radicals increases germicidal activity. Substitution of alkyl radicals in the benzene ring weakens activity. A change which decreases soly will decrease germicidal activity. The majority of dyes in this group are more active at a p_H of 6.5 than at 7.5 or 8.5. Many individual effects of p_H and substitutions in the oxazine, di- and triphenylmethane, xanthone, acridine, quinoline, thioflavine, thiazine, nitro, azo and alizarin dyes were noted, but no definite generalizations were drawn. J. T. M.

The staining of lepra bacilli. (TTO RUEDEL *Centr. Bakt. Parasitenk. I. Abt.* 107, 357-8(1928). The following technic will differentiate between tubercle and lepra bacilli. Apply carbolfuchsin (basic fuchsin, 1 g.; alc., 10 cc., phenol, 5 g. and water up to 100 cc.) and heat till steam rises. Wash several times with 5% H_2SO_4 . Wash with water. Apply Joeffler's methylene blue for 30 to 60 sec. Wash with water. Wash 2 to 5 sec. with 70% alc. and then 1 to 3 sec. with abs. alc. Mount in toluene balsam.

JOHN T. MYERS

The influence of metallic salts on the development of bacteria. I. Silver salts. H. A. ANDRESEN *Centr. Bakt. Parasitenk. I. Abt.* 105, 444-55(1928).—Ag salts react with peptone and there is no equal established between bound Ag and the Ag ion. Bound Ag is slowly freed by Na₂S. In a protein and peptone free medium, the Ag-ion concn. can be kept quite constant, and concns. of $0.16 \cdot 10^{-11}$ to $0.10 \cdot 10^{-11}$ inhibit bacterial growth. Only Ag as ion has inhibiting power. The effect increases with the alkyl of the medium.

JOHN T. MYERS

The protamine bacteria. I. E. DEN DOOREN DE JONGE. *Centr. Bakt. Parasitenk. II. Abt.* 71, 193-232(1927). The term protamine bacteria is applied to that group of organisms which are Gram negative, non-spore bearing rods which can split one or more of the lower alkylamines. Of a large no. of oxidizing bacteria studied, only a few species met these requirements. The action of many bacteria was studied on a large list of org. compds. including acids, alcs., amino acids, amides, ureides, guanidine and purine derivs.

JOHN T. MYERS

Spore formation and colloid changes. GYULA DARÁNYI *Centr. Bakt. Parasitenk. II. Abt.* 71, 353-7(1927).—Sporulation in bacteria does not depend on such factors as O tension, p_H , salt concn. or temp.; but on colloidal dispersion. Hence dehydration will induce spore formation in very young cells.

JOHN T. MYERS

The influence of sugars on the metabolism of yeasts. A. OSTERWALD. *Centr. Bakt. Parasitenk. II. Abt.* 71, 357-72(1927).—In pure yeast cultures, the type of sugar in the medium influences the rate of growth and the kind and amt. of metabolic products. The effect does not depend on content of acid, alc. or N compds. Most sugars favor the growth of yeasts.

JOHN T. MYERS

Studies on amylase formation by several strains of Aspergillus. H. KNAPP. *Centr. Bakt. Parasitenk. II. Abt.* 71, 372-98(1927).—Amylase is formed faster and in larger amts. at the optimum growth temp. and with optimum type of medium. Enzyme formation and growth are proportional. Sporulation begins when diastase formation stops. Acid inhibits diastase production. Diastase is not used by the organism.

JOHN T. MYERS

Biochemical differential characteristics of the lactic acid bacteria. I. **Methods of investigation.** I. A. MAKRIKOV. *Centr. Bakt. Parasitenk. II. Abt.* 71, 399-407(1927).—It is essential to use a simple medium and the following was selected. K_2HPO_4 , 0.05 g.; $MgSO_4$, 0.05 g.; NH_4MgPO_4 , 1.5 g.; peptone, 0.2 g.; "manganpepton," 0.1 g.; lactose, 0.3 g.; $CaCO_3$, 0.2 g.; and cond. water 100 cc. All lactic acid bacteria belong to a single physiol. group.

JOHN T. MYERS

Milk as a culture medium for the lactic acid bacteria. SÖNCKE KNUDSEN AND A.

SÖRENSEN. *Centr. Bakt. Parasitenk. II Abt.* **71**, 500-7(1927).—The addn. of yeast autolysate frequently increased the yield of lactic acid. JOHN T. MYERS

The proteolytic action of certain lactic acid bacteria. W. H. PETERSON, L. M. PRUESS AND E. B. FRED. *J. Bact.* **15**, 165-78(1928).—Of 22 strains of lactic acid bacteria, 13 were mannitol fermenters and 9 were not. Three different media varying in N content from 105 to 326 mg. per 100 cc. were used. Formation of non-protein N, amino N, and of NH_3 was taken as a measure of proteolysis. Non-protein N was the most abundant form of N produced, there being an increase in most cases and a decrease in only a few. The max. increase occurred in a nitrose yeast-water medium contg. 326 mg. of N per 100 cc. where 89 mg. per 100 cc. were produced, making about 51% of the total N present after incubation. In a few cases more amino N was consumed than was formed, the variations ranging from a decrease of 24.8 mg. to an increase of 33.2 mg. per 100 cc. of culture. NH_3 production was small in all cases and sometimes did not equal its consumption. Proteolysis continued long after the destruction of sugar ceased. There is a long bibliography. JOHN T. MYERS

Description of an organism found in solutions of sodium caseinate. RUDOLPH GAHL. Univ. of Calif. *J. Bact.* **17**, 35-42(1928).—The name *chromobacter caseinum* is applied to the organism. JOHN T. MYERS

The bactericidal destruction of acetyl methyl carbinol. O. B. WILLIAMS AND MARIE B. MORROW. Univ. of Texas. *J. Bact.* **17**, 43-8(1928).—Acetylmethylcarbinol is destroyed by certain strains of the colon-aerogenes group of bacteria, chiefly *Aerobacter aerogenes*; by the green fluorescent bacteria; and by all of the aerobic spore formers tested. It is not destroyed by the representatives tested of the *Salmonella*, *Eberthella*, *Proteus* or *Serratia* groups. It is probable that the compd. serves as a source of C. JOHN T. MYERS

Studies on the proteolytic bacteria of milk. I. A medium for the direct isolation of caseolytic milk bacteria. WILLIAM C. FRAZIER AND PHILIP RUFF. U. S. Dept. of Agr. *J. Bact.* **17**, 57-63(1928).—The following casein agar has been adopted. Soak 3.5 g. of casein in 150 cc. of distd. water for 15 min. and add 72 cc. of satd. lime water. Shake until the casein is almost dissolved, add 0.35 g. of K citrate and shake until soln. is complete. Add 10 cc. of double-strength beef infusion and make up to 300 cc. Add 100 cc. of 0.15% CaCl_2 soln. and 100 cc. of a soln. which contains 0.105% of $\text{NaH}_2\text{PO}_4 \cdot 2\text{H}_2\text{O}$ and 0.035% of KH_2PO_4 . Divide the soln. into 50-cc. portions in 200 cc. flasks and autoclave 15 min. at 20-lbs. pressure. The p_{H} value should be 7.0. Sterilize likewise 50-cc. portions of 3% washed agar. One flask of each is heated in a steamer and mixed hot for use. II. Action of proteolytic bacteria of milk on milk. *Ibid.* 65-78.—Data are given to show the change in amino N, titratable acidity, H-ion concn., and NH_3 in milk by 229 cultures of proteolytic milk organisms. Tests were made for tryptophan in cultures in both autoclaved and steamed milk held for 10 days at 30°. The cocci were found to be mostly acidoproteolytic and to produce only a moderate amt. of amino N in milk. The Gram-negative rods varied from weakly to actively proteolytic. The Gram-positive rods fell into 3 groups: (1) high acid, low amino N, (2) low acid, low amino N and (3) low acid, high amino N. JOHN T. MYERS

Decomposition of nitrates by bacteria. M. P. KORSAKOVA. *Bull. acad. sci. union republ. soviet socialist* **1927**, No 15 7, 1221-50. In the reduction of nitrates by bacteria under anaerobic conditions the oxidation of an org. substance present is the source of energy necessary for the reaction. If this reaction takes place in presence of glucose the concn. of H ions of the soln. remains unchanged, but in case citric acid plays the role of the org. substance to be oxidized, the soln. gradually becomes alk., and the quantity of CO_2 sepd. per unit of free N is twice the amount of CO_2 sepd. in presence of glucose. The reduction of nitrates takes place in 3 phases: (1) $2\text{HNO}_3 \rightarrow 2\text{HNO}_2 + \text{O}_2$; (2) $2\text{HNO}_2 \rightarrow \text{intermediate} + \text{O}_2$; (3) $\text{intermediate} \rightarrow \text{N}_2 + \text{H}_2\text{O} + \text{O}$. The nature of the intermediate has not been established. In the course of reduction of nitrates, glucose which is contained in soln. is entirely oxidized to CO_2 . The relationship which has been established between the amount of oxidized glucose and that of reduced nitrate as well as that of CO_2 and N formed points to the following reactions: $\text{C}_6\text{H}_{12}\text{O}_6 + 6\text{O}_2 = 6\text{CO}_2 + 6\text{H}_2\text{O}$, $5\text{C}_6\text{H}_{12}\text{O}_6 + 24\text{KNO}_3 = 24\text{KHC}_2\text{O}_4 + 6\text{CO}_2 + 12\text{N}_2 + 18\text{H}_2\text{O}$. BERNARD NELSON

The rate of reduction of methylene blue by *Bacillus coli*. G. S. EADIE. *J. Gen. Physiol.* **11**, 459-68(1928).—The relation between substrate concn. and velocity of reduction of methylene blue and other oxidation-reduction indicators of Clark by *B. coli* in the presence of succinic acid and glucose was studied. The rate of reduction is expressed by the equation, $v = a + b \log c$, in which a and b are consts. and c is the concn. With the concns. used, increasing the p_{H} of the soln. increased the rate of the reduction

of methylene blue. Compared with the system, barley amylase and starch, this system shows the same relation between substrate concn. and velocity but the effects produced by altering p_H and the temp. on this relation are quite different in the two cases. The relation between velocity and substrate concn. does not appear to be governed by the mass law; the indications are that adsorption plays an essential part in the process.

C. H. RICHARDSON

The oxygen consumption of luminous bacteria. E. N. HARVEY. *J. Gen. Physiol.* 11, 469-75(1928).—The O_2 consumption of luminous bacteria detd. by the Thunberg micro respirometer and by the time elapsed before the luminescence of an emulsion of luminous bacteria in sea water begins to dim when more than 99% of the dissolved O_2 has been consumed, agree exactly. At 21.5° the consumption is 4.26×10^{-11} mg. O_2 per bacterium, or 2.5×10^1 mg. per kg., and 5.6 mg. per sq. m. of surface of the organism. Expts. show that O_2 must diffuse into the bacterium much more slowly than through gelatin or connective tissue but not as slowly as through chitin. Comparison of the O_2 consumption of organisms or tissues should be in terms of O_2 used per unit wt. with sufficient O_2 tension so that the consumption is independent of the tension.

C. H. RICHARDSON

The stability of carbohydrate media. LUCY D. HENRY AND M. S. MARSHALL. *J. Lab. Clin. Med.* 12, 474-7(1927).—Twenty % unheated filtered solns. of dextrose, lactose, maltose, sucrose, mannitol and levulose stored at 5° appear to retain their sp. properties with regard to biologic fermentation for a period of at least 20 months; xylose similarly prepd. is stable for at least 12 months. The addn. of such solns. to culture medium aseptically, to avoid heating, specifically a beef ext. sugar-free semi-solid agar, furnishes an excellent means of checking fermentation characteristics of bacteria, but the storage of the medium after the addn. of the carbohydrate for more than a few days renders the fermentation reactions nonspecific. Variation in the fermentation of some carbohydrates by some bacterial strains may under unknown circumstances occur, but every possible means of demonstrating that such variation does not occur should be exhausted before accepting such a conclusion. Fermentation reactions should be read, for example, at 4, 6, 8, 24 and 48 hrs. from the time of inoculation, for it is essential that one view fermentation as a progressive process with several possibilities rather than as a static definitely positive or negative matter. THOMAS G. PHILLIPS

The presence of certain xanthine substances and their derivatives in the potato. G. G. SCHWEIZER. *Arb. Biol. Reichs. Land-Forstw.* 15, 1-18(1926); *Chem. Zentr.* 1927, I, 908.—To explain the "mosaic disease" of the potato, the contents of purine bases in the tuber, in the germ and leaves were detd. Xanthine, guanine and hypoxanthine were isolated and in the germ adenine was identified. The purine content of germinated tubers is essentially higher than that of tubers which have not germinated, while the purine content of the germs is between these 2 values. The older the germ, the higher its xanthine content. The xanthine content of the tubers can, without analyzing, be estd. colorimetrically with $KClO_3$ and concd. HCl . From the tubers was isolated an enzyme which converts colorless solns. of adenine, guanine, hypoxanthine and xanthine into yellow solns., probably alloxan. It is concluded that xanthine has some causal relation to the yellow mosaic disease. There is also a discussion of the influence of sunlight.

C. C. DAVIS

The influence of various factors on the accumulation of alkaloids in the leaves of *Datura stramonium* L. var. *inermis*. WITOLD PŁOSKI. Krakau. *Roczniki Nauk Rolniczych I Lesnych* 16, 186-216; *Chem. Zentr.* 1927, II, 291.—The alkaloid content of the leaves of *Datura stramonium* is independent of N and K fertilization. It increases with the size and with the age of the leaves and is greater at the end of the night than in the evening.

C. C. DAVIS

Photosynthesis of cultivated plants, its relation to yield and its dependence on

climate and soil. H. LUNDEGÅRDH. *Medd. Centralanstalt. försöksväsendet jordbruks. Avdeln. lantbruksbotan.* 43, 3-97(1928).—A summary of a series of investigations on the assimilation of CO_2 by plants, carried out from an ecological point of view over a period of several years. New methods and app. for detn. of the assimilation under varying conditions and also of the controlling factors of light intensity, concn. of CO_2 , and temp. were developed. The importance of CO_2 as a growth factor is shown in expts. with beans, cucumbers, tomatoes and sugar beets. The CO_2 pressure in the air around growing plants (the CO_2 factor) and its dependence on soil respiration and climatic factors is considered. Some of the conclusions are as follows: (1) The absolute rate of assimilation per unit leaf-surface at 18° to 20° is practically the same in different plants, being about 8.42 to 9.78 mg of CO_2 per hr. per 50 sq. cm. (2) The increase by a certain % in one factor results in an increase in the assimilation rate which is relatively greater, the more the factor in question is in min. (3) The temp. optimum of the assimilation is changed with the light factor and the CO_2 factor so that an increase in each of these factors gives rise to a higher temp. optimum, and a decrease results in a lower temp. optimum. If V_0 = a given intensity and V_1 = a higher intensity of a certain factor, and if F = a biol function (e. g., assimilation of CO_2) then the quotient $F_1/V_1 \cdot F_0/V_0$ shows how much F increases or decreases when the factor is increased. The quotient is a measure of the relative effect of the factor upon assimilation. (4) The activity of soil respiration controls the CO_2 content of the air up to 5 m. above the soil surface. (5) A certain relationship exists between the cloudiness of the sky and the CO_2 factor, which is due to the influence of light upon the assimilation. (Much cloudiness = low light-intensity = weak assimilation = low CO_2 consumption = high CO_2 factor.) (6) Economically satisfactory results may be obtained by the application of CO_2 to greenhouse cucumber plants. (7) The effect of CO_2 fertilization increases with the temp. and the light intensity. (8) In certain expts. with oats, 50% of the total fertilization effect was due to the action of CO_2 . E. O. ELLINGSON.

Changes in hydrogen-ion concentration induced by carbon dioxide in relation to the germination of spores of *Ustilago levis*. M. F. HOWE. *Phytopathology* 16, 69-70 (1926); *Expt. Sta. Record* 58, 544.—In attempting to det. the effect of fragments of living plant tissue on the increased germination of the spores of *U. levis*, the influence of CO_2 given off by the tissue on the H-ion concn. was studied. Spore suspensions made by placing spores in tap water in suitable dishes showed that the highest percentages of germination occurred at p_{H} 4.9. A continuous flow of CO_2 caused the p_{H} to vary from 6.7 to 4.9, a similar variation having been observed where the source of CO_2 was fragments of living plant tissue. Spore suspensions confined in an atm. consisting of different percentages of CO_2 failed to produce the optimum of p_{H} 4.9, but by a continuous flow of CO_2 into the spore suspensions this optimum was obtained, as well as a high percentage of germination comparable to that noted in cultures where fragments of plant tissues were present. H. G.

Chemical composition of vegetable seed fats in relation to the natural orders of plants. THOMAS P. HILDITCH. Univ. of Liverpool. *Proc. Roy. Soc. (London)* B103, 111-7(1928).—In certain plant orders, a marked tendency exists toward the production of specific fatty acids. Thus, lauric, myristic, erucic and petroselinic (Δ^8 -octadecenoic) acids, in their nature and proportion, characterize the orders, Palmae, Myristaceae, Cruciferae and Umbelliferae (with the very closely related Araliaceae), resp. Fair to considerable amts. of oleic and linoleic acids and minor amts. of palmitic, arachidic, lignoceric and other acids may also be present. JOSEPH S. HEPBURN.

Feeding fungi with cobaltamine complex salts. KONO KONOSHITA. *Acta Phytchim.* 3, 31-49(1927).—*Aspergillus niger* (I), *A. oryzae* (II) and *Penicillium glaucum* (III) were grown for periods of 35 days on a culture medium contg. KH_2PO_4 , MgSO_4 , and sugar, with the following 19 compds. as sources of N: (1) NaNH_2 , (2) KNO_3 , (3) NH_4NO_3 , (4) $[\text{Co}(\text{NH}_3)_2\text{Cl}]_2$, (5) $[\text{Co}(\text{NH}_3)_2\text{Cl}]_2\text{Cl}_2$, (6) $[\text{Co}(\text{NH}_3)_2\text{Cl}]_2\text{C}_2\text{O}_4$, (7) $[\text{Co}(\text{NH}_3)_2\text{Cl}]_2(\text{HSO}_4)_2\text{SO}_4$, (8) $[\text{Co}(\text{NH}_3)_2\text{H}_2\text{O}]_2(\text{C}_2\text{O}_4)_2 \cdot 4\text{H}_2\text{O}$, (9) $[\text{Co}(\text{NH}_3)_2\text{H}_2\text{O}]_2\text{Cl}_2$, (10) $[\text{Co}(\text{NH}_3)_2\text{NO}_2]_2\text{Cl}_2$, (11) $[\text{Co}(\text{NH}_3)_2\text{ONO}]_2\text{Cl}_2$, (12) $[\text{Co}(\text{NH}_3)_2\text{SCN}]_2\text{Cl}_2$, (13) $[\text{Co}(\text{NH}_3)_2(\text{NO}_2)_2]_2\text{Cl}(\text{Croce})$, (14) $[\text{Co}(\text{NH}_3)_2(\text{NO}_2)_2]_2\text{Cl}(\text{Flavo})$, (15) $[\text{Co}(\text{NH}_3)_2(\text{H}_2\text{O})_2]_2\text{SO}_4 \cdot 3\text{H}_2\text{O}$, (16) $[\text{Co}(\text{NH}_3)_2\text{CO}]_2\text{SO}_4 \cdot 3\text{H}_2\text{O}$, (17) $[\text{Co}(\text{NH}_3)_2(\text{H}_2\text{O})\text{Cl}]_2\text{Cl}_2$, (18) $[\text{Co}(\text{NH}_3)_2(\text{NO}_2)_2]_2$, (19) $[\text{Co}(\text{NH}_3)_2(\text{NO}_3)_2]$. I showed the best growth with 3, 2, 13, 18, 15, resp. and none with 1, 16, 17; II grew best with 2, 18, 14, 13, 5, none at all with 7, 15, 16, 17; with III the best growth occurred with 2, 3, 4, 7, 6 and no growth resulted with 5, 10-13, 15-19. The cobaltamine-fed organisms averaged 2.18% ash, contg. 14.71% Co. Where a lack of N was apparent, especially with II, a known γ -pyronehydroxymonobasic acid, kojic acid, was formed and isolated. This sometimes amounted to 33% of the sugar used. *Aspergillus niger*, grown with cobaltamines, also produces an

unusual amt. of org. acids. Citric, malic, succinic, tartaric and oxalic acids were detected.

Constituents of *Typha angustata* Bory et Chaub. MASAO FUKUDA. *Tohoku Imp. Univ. Sci. Repts* 17, 711-7(1928).—See *C. A.* 22, 1993.

E. H.

Red root tips. HANS MOLISCH. *Ber. deut. botan. Ges.* 46, 311-7(1928).—Anthocyan is found in the vegetative point of the roots of many plants belonging to the Crassulaceae, Saxifragaceae, Balsaminaceae, Melastomaceae and Compositae. The occurrence of this pigment in this area may often be an indication of plant relationship. L. P. M.

The influence of *Ustilago tritici* on the physiological functions of wheat. A. L. KOURSSANOW. *Univ. of Moscow. Rev. gén. botan.* 40, 277-302, 343-71(1928).—Respiration is more rapid in infected plants than in healthy plants, the difference increasing with age until it reaches 40% at the time of heading. The respiratory quotient remains unchanged. Transpiration is increased by 20-30% in infected plants. Diseased plants show stronger CO₂ assimilation, varying from 4 to 30% over healthy plants. For the first 20-25 days the infected plants grow more rapidly, after which there is a slowing down so that at efflorescence diseased plants have a dry wt. 60-64% of healthy plants. The % of total carbohydrates is about the same, but diseased plants have a higher content of sol. sugars. Total N and albuminoid N are not affected.

LAWRENCE P. MILLER

Interior medium of different organs of the potato during the growth of the plant. J. CHAUSSIN. *Compt. rend.* 186, 1649-51(1928); cf. *C. A.* 19, 843.—Analyses were made of the seed piece (*mere*) and leaves on May 22 and of these and new potatoes on June 10. On June 24 and July 10 the analyses were made of the leaves and new potatoes. From the results it is emphasized that the ratio of the ash to the ext. in the bouillon of the leaves is const. during growth. The results are closely parallel to those obtained in a previous study with wheat leaves. This suggests the existence of a *veritable physiologic ratio*, which is discussed at length.

L. W. RIGGS

Proximate principles of seeds of two species of *Combretum*. V. HASENFRATZ AND R. SUTRA. *Compt. rend.* 186, 1860-2(1928).—The seeds of *Combretum bernierianum* and of *C. subumbellatum* contain about 10% of fat material consisting principally of palmitin and olein, also a min. of 4% of sucrose which is easily isolated in pure form from the seeds. A glucoside is probably present.

L. W. RIGGS

Phenomena preparatory to germination. JEAN DUFRENOY. *Compt. rend. soc. biol.* 98, 1497-8(1928).—Beans sterilized with CaOCl₂ were divided in 2 series (a) with the outer coatings removed and (b) with the outer coatings not removed. These were placed in tubes with moist cotton and were kept at 27° in the thermostat. Seeds of series (a) germinated in 2 days, series (b) in 8 days. At 21° the germination was also 2 and 8 days. At 15° there was no germination in either series of seeds. (Cf. Morinaga, *C. A.* 21, 943.)

L. W. RIGGS

Contribution to the chemical study of Malvaceae. J. PIERAERTS AND F. DE WINTER. *Mut. grasses* 20, 8224-7(1928); cf. *C. A.* 22, 2283.—The oil obtained from *Honckenya ficifolia* Wild resembles cottonseed oil. The fibers of this plant are used by the natives for making very strong ropes. Phys. and chem. properties of *Berria ammanilla* Roxb and *Corchorus olitorius* also are given.

Investigation of the hypothetical combined pentose and the so-called free pentose with inferences on the composition of pectin. RONALD B. MCKINNIS. State College, Washington. *J. Am. Chem. Soc.* 50, 1911-5(1928).—Apples and apple pectin contain no pentose, either free or combined. The furfural comes from arabinose, which in turn is derived from galacturonic acid. Arabinose is only an intermediate product in the formation of furfural from galacturonic acid. With weak acids some arabinose can be obtained before it is decomp'd. The digalacturonic acid is probably the nucleus unit of the pectin mol.

C. J. WEST

Acids of figs. E. K. NELSON. U. S. Dept. Agr. *J. Am. Chem. Soc.* 50, 2012-3(1928).—Acetic and citric acids were found in Adriatic figs and acetic, citric and a small quantity of malic acids were identified in Calimyrna figs. Adriatic black neck figs contained more than 10 times as much free AcOH as the normal Adriatic figs. Less citric acid was found than in normal figs. Normal Calimyrna contained 0.26 g. per kg. of free AcOH and 3.5 g. of citric acid, besides a small quantity of malic acid. In Calimyrna figs affected with internal rot the free AcOH amounted to 0.56 g. per kg. and the citric amounted to 3.3 g. per kg.

Effect of renewal of nutrient solutions upon the growth of culture plants and its relation to aeration. TSUNG-L& LOO. *Japan J. Botany* 4, 71-98(1928).—Renewal of

culture soln. every 24 hrs. had no effect on the direction of the reaction change; the change of the reaction in the soln. was generally retarded to some extent by the renewal and consequently this treatment produced better results in the growth of the culture plants. In the solns. where no remarkable retardation of reaction change was produced by renewal, such as the NH_4Cl and $(\text{NH}_4)_2\text{SO}_4$ cultures, the increase in the yield was not as large as in the cultures whose reaction was kept almost const. by the treatment. The effect of renewal of soln. on the growth of paddy rice seedlings was found to be different from that on the growth of wheat. In the case of NH_4HCO_3 cultures, no beneficial effect was observed on renewal of the soln. Aeration of nutrient soln. has no influence on the growth of the seedlings. The O supply may not be a predominant factor in the beneficial effects of the renewal of the soln. C. J. WEST

Plant sterols. LEOPOLD SCHMID AND GERHARD BILOWITZKI. Univ. Vienna. *Monatsh.* 49, 98-106 (1928); cf. C. A. 21, 1271.—The sterol mixt. obtained from *Radix bardanae*, *Ulmus campestris* and *Ficus carica* has, in each case, been sepd. into stigmasterol and sitosterol by means of the insoly. of the tetrabromoacetate of the former. In each case the sterol was identified by a no. of derivs. C. J. WEST

PHILIP B. HAWK

Relative food values of brown (from "entire" wheat grain) and white (from endosperm of grain) wheaten flour, and their comparative potency for prevention of xerophthalmia in guinea pigs. E. J. SHEEHY. *Proc. Roy. Irish Acad.* 37, 415-25 (1927).—Guinea pigs fed on mangels (20 g.), white flour *ad lib.*, and 0.4 g. hydrogenated soybean oil decline in wt. and contract xerophthalmia in 3-7 weeks. The xerophthalmia, but not the decline in wt., is cured when cod-liver oil is substituted for hydrogenated oil. When brown flour made from the entire wheat grain is substituted for white flour, xerophthalmia occurs much more rarely, although the animals decline in wt. If the diet is restricted, brown flour appears to be preferable as a food to white flour. B. C. A.

Reaction of irradiated ergosterol (vitamin D). A. STEIGMANN. Heidelberg. *Kolloid-Z.* 45, 165-6 (1928).—With fuchsin H_2SO_4 reagent, irradiated ergosterol gives a violet color, whereas ergosterol or cholesterol which has not been radiated gives no color. This color reaction is particularly delicate if the reagent contains a little H_2SO_4 , and when the ergosterol has been irradiated in an atm. of CO_2 . Ammoniacal AgNO_3 is reduced to a stable colloidal Ag sol by irradiated ergosterol but not by the unrayed compd. These reactions suggest that vitamin D is an aldehyde or unsatd. ketone.

F. A. CAIORI

The effect of the quantity of calcium carbonate (fed) and of age on the calcium and phosphorus metabolism of Yorkshire swine. ISTVAN WEISER AND A. ZAITSCHEK. Royal Hungarian Animal Physiol. Expt. Sta., Budapest. *Fortschritte Landw.* 3, 451-5 (1928).—In 4 expts., shoats fed normal quantities of CaCO_3 absorbed an av. of 80.5% of the Ca, 91.3% of the P_2O_5 and 79.3% of the N fed; with double the normal quantities of CaCO_3 , the averages were 23.64, 16.57 and 83.1%, resp., indicating an unfavorable effect on the absorption of Ca and P_2O_5 and slight effect on the digestion of N-contg. feed. Likewise the higher dose of CaCO_3 led to retention of 13.25 g. of CaO and 4.93 g. of P_2O_5 per 100 kg. of live wt., as compared with 31.0 g. and 24.8 g., resp., with a normal dose of CaCO_3 . This highly diminished Ca and P_2O_5 assimilation expressed itself in a highly rachitic condition of the exptl. animal. Comparative metabolism expts. with shoats ranging in age from 16 to 28 weeks showed that the quantities of Ca and P_2O_5 assimilated steadily decreased with increasing age, indicating slower development of the skeleton in the older animals. The N assimilated, however, steadily increased to an age of 30 weeks and was independent of the quantity and quality of the protein feed.

P. R. DAWSON

The plural nature of vitamin B. ALBERT G. HOGAN AND JESSE E. HUNTER. Univ. Mo. *J. Biol. Chem.* 78, 433-44 (1928).—Expts. were made on rats, chicks and pigeons fed with a synthetic diet and yeast concentrate as a source of vitamin B. When the vitamin B preps. were exposed to ultra-violet light for 10 hrs. the growth-promoting power was lost

but the antineuretic power was retained. On the other hand after autoclaving the yeast and the yeast concentrate for 2 hrs. at 120°, the antineuretic property was destroyed but the growth-promoting power was retained. However, a mixt. of the two in all cases provided a potent source of vitamin B, the results in all cases being as satisfactory as with untreated yeast. These results are brought forward as proof that vitamin B is a mixt. of at least 2 distinct vitamins. It is proposed to retain the designation of vitamin B for the antineuritic factor and to designate the growth-promoting factor as vitamin F.

H. J. DEUEL, JR.

Studies in nutrition. I. Growth, reproduction, and lactation on diets with different proportions of cereals and vegetables. MARY SWARTZ ROSE AND ELLA L. MCCOLLUM. Columbia Univ. *J. Biol. Chem.* 78, 535-47 (1928).—A study of the efficacy of diets of children for prolonged nutrition in the rat. The diets were as follows: *H*, cereal (flour) 50% of calories, vegetables 10%; *M*, cereal 37.5% and vegetables 15%; and *L*, cereal 25% and vegetables 20%. The diets also contained dextrin, butter substitute, meat residue and NaCl. There was uniform food consumption on all the diets for 4 generations with growth curves exceeding those of Donaldson. There were more infertile matings on diet *L* but the age of the mothers at first reproduction showed no significant differences with the different diets. Reproduction was better in the second and third generations than in the first but lactation was poorer in the later generations as detd. by the no. of young successfully reared. Diets satisfactory for growth and reproduction were thus unsatisfactory for lactation. **II. The effect of adding egg to a diet already adequate.** *Ibid* 549-55.—When an egg was added to diet *M* (see above) making up about 3% of the wt. of the diet, there was a better growth of the young fed on this diet from the 28th to the 56th days of life and an earlier maturity of the females as detd. by the age of the mother when the first litter was born. Likewise a larger no. of females bore young and the capacity for lactation was improved. The hemoglobin content of the blood which had previously been shown to increase after addn. of egg to a similar basal diet in children was unchanged in the rats. The importance of milk and eggs as staple foods is emphasized.

H. J. DEUEL, JR.

Lipoid and fat metabolism during fattening. HANS KNAUER. *Z. physiol. Chem.* 176, 151-72 (1928).—The lipoid values of the blood are relatively low in the hog. In the course of fattening a distinct decrease is noted in the several fractions (phosphatides, cholesterol, free fatty acids), but this is not due to a diln. of the blood. The changes are most pronounced in the serum, while the lipoids of the erythrocytes vary only within narrow limits. The rate of sedimentation of the blood corpuscles also diminishes with increasing fattening. A comparison of serum with oxalate or citrate plasma shows that the values are consistently lower in the plasma, in consequence of the addn. of the chem. agent. In geese also the normal fattening with increasing body wt. is accompanied by a slow but const. decrease in the several lipoid fractions. With forced fattening the lipoid values remain low or even diminish as long as the organism takes care of the alimentary fat, but when a const. wt. is attained the lipoid values increase considerably. A lactemia then occurs and the birds in this condition present a sickly appearance. Fattening is not possible on a ration of noodles, potato flour, sugar and protein, the birds becoming acutely sick, perhaps for lack of vitamins. In the final stage there is lactemia which, however, might be attributed to a migration of depot fat. The organs of geese fattened in various ways show distinct differences in wt., especially of the liver and kidneys.

A. W. DOX

Sugar beet by-products for fattening livestock. E. J. MAYNARD AND B. W. FAIRBANKS. Colo. Agr. Coll., *Bull* 269A, 1-19 (1928).—Sugar beet tops, wet beet pulp, pressed beet pulp, beet molasses and dried molasses beet pulp were used to advantage in rations for fattening steers and lambs.

C. R. FELLERS

The relation of maternal diet to hemorrhage in the new-born. C. U. MOORE AND J. L. BRODIE. *Am. J. Diseases Children* 34, 53-61 (1927); *Physiol. Abstracts* 12, 559.—Expts. with rats show that a maternal diet deficient in vitamin B causes either abortion or death of the young at birth or during the nursing period; in these cases symptoms of advanced beri-beri are present and a hemorrhagic condition of many organs is found at autopsy. A human case is reported in which the mother's prenatal diet was very deficient in vitamin B; profuse hemorrhage occurred during delivery, and the baby died after a few days; there were no external abnormalities, but symptoms of hematuria, jaundice and diarrhea were present, and hemorrhages were found in most of the organs, together with a myelin degeneration of certain nerves similar to that of beri-beri. The authors suggest that vitamin deficiency may be a cause of otherwise unexplained hemorrhage of the new-born.

H. G.

The influence of the administration of cod-liver oil to the mother on the develop-

ment of rickets in the infant. A. A. WESSCH. *Bull. Johns Hopkins Hosp.* 40, 244-58 (1927); *Expt. Sta. Record* 58, 90-1.—The subjects of this study were colored babies from Johns Hopkins Hospital. The mothers of 3 out of every 4 were given 1 teaspoonful of cod-liver oil three times a day from the birth of the babies and were instructed to continue taking the oil until the babies were weaned. No oil was given any of the babies. At the end of 6 months Röntgenograms and blood analyses were obtained from all of the babies whose mothers had continued the treatment. Of 260 patients originally enrolled, only 47 were available at the end of the time, the mothers of 9 of whom had had no cod-liver oil. Although there were individual cases showing wide variation in the extent of rickets regardless of the cod-liver oil, the av. extent of rickets as judged both by x-ray and the Ca-P product varied inversely with the amt. of cod-liver oil taken by the mothers. Of the entire no. of cases, only 6 were examd. in May, when a seasonal reduction in rickets might have taken place. The author concludes that "when cod-liver oil is given to a mother a certain amt. of the antirachitic vitamin does pass into her milk, and that even though in individual cases the amount so transmitted to the infant may be insufficient to prevent manifestations of the disease, nevertheless when the average degree of rickets existing in a group of such infants is considered, the transfer has been sufficient to raise considerably the Ca-inorg. P product of the blood serum and to lessen the Röntgenographic evidences of disease." H. G.

The nature of the structural changes in nerve endings in starvation and in beriberi. H. H. WOOLLARD. *J. Anat. [London]* 61, 283-97(1927); *Expt. Sta. Record* 58, 297.—The results are reported of the histological examn. of the nerve tissues of the exptl. rats in the previously noted investigation of Drummond and Marrian (*C. A.* 20, 1667). A striking similarity was noted between the tissues of the rats deprived of vitamin B and of all food, although the lesions were less marked in the latter case. The only changes noted were in the intermuscular medullated motor and sensory nerves and their endings, these changes rapidly subsiding at a little distance from the muscles. The sympathetic and central nervous systems showed no abnormal anatomical changes. These findings confirm the opinion of Drummond that beriberi, as it occurs in rats under exptl. conditions, is really starvation arising from inability to assimilate food in the absence of vitamin B. H. G.

The complex nature of vitamin B as found in wheat and corn. C. H. HUNT. Ohio Agr. Expt. Station. *J. Biol. Chem.* 78, 83-90(1928).—Rats on a vitamin-B-free diet, supplemented with autoclaved yeast, died with polycneuritis or emaciation. Expts. with wheat or corn with and without the addn. of autoclaved yeasts indicate that in the former the limiting factor for growth is vitamin G. This vitamin is supplied by autoclaved yeast and when present in sufficient amt permits growth with a diet contg. 15% wheat. ARTHUR GROLLMAN

The influence of a diet, high in butter fat, on growth, blood formation and blood destruction. G. L. MULLER. Boston City Hosp. *J. Clin. Investigation* 5, 521-9 (1928).—The effect of a diet contg. 86.5% of its caloric intake in the form of butter fat was studied on growing and adult rats with reference to growth, maintenance, blood formation and blood destruction. Young rats grew to adult size and adults added to their wt. No evidence of injury to the *hematopoietic* system was observed. Necropsy findings were normal except for an increase in abdominal fat, fatty infiltration of the liver and a slight increase in the fat cells of the bone marrow. ARTHUR GROLLMAN

The digestibility of white of egg. I. G. MACDONALD and E. GORDON YOUNG. Dalhousie Univ., Halifax, N. S. *Proc. Trans. Nova Scotian Inst. Sci.* 16, 197(1928).—Uniform samples of egg white were coagulated at 100° for periods of time varying from 2 to 30 min. and their digestibility determined *in vitro*. No differences existed in the rate of peptic digestion, whether the period of coagulation was long or short. A. L. H.

Recent advances in science: Nutrition. LESLIE J. HARRIS. Univ. Cambridge. *Science Progress* 23, 68-74(1928).—Review of recent work on the mode of action of vitamin D with especial reference to the question of its regulation of gut acidity. JOSEPH S. HEPBURN

The relation of the specific-dynamic action in man to the type of food ingested. DIETRICH JAHN and EDGAR STRÖSSENREUTHER. *Deut. Arch. klin. Med.* 159, 152-63(1928).—The specific-dynamic action can be varied both quant. and qual. by changing the amt. of protein contained in test meals; quant. also by the previous ingestion of protein, but with no great regularity. The greater the amt. of protein previously ingested, the more marked was the effect observed during the first hr. after the test meal. P. Y. JACKSON

The specific-dynamic action of food, and the laws of gas-exchange. DIETRICH JAHN. *Deut. Arch. klin. Med.* 159, 335-61(1928).—Test meals were given accompanied

by acid drinks or by Na_2CO_3 (1 g. 4 times daily). The sp.-dynamic action, as measured by O_2 consumption, was 31.7% greater after the acid meal than after the alk. A similar test, carried out after the subcutaneous injection of 1 mg. suprarenine, showed a difference of 40%. In a severe case of Basedow's disease a much greater rate of O_2 consumption was noted; there were two distinct phases, the first max. being reached in 1-3 hrs., and the second in 4-6 hrs. A decided decrease in intensity of the first phase was brought about by the injection of 40 units of insulin; the opposite effect was noted upon the injection of 0.6 mg. histamine. An increased excretion of CO_2 was accompanied by a decreased consumption of O_2 , and by an alk. urine; this rule holds even when the sp. dynamic effect is changed by the injection of various hormones. The respiratory quotient is, therefore, no index of the nature of the oxidation processes taking place in the tissues. Intravenous injection of acid salts, such as 20 cc. $\text{N NaH}_2\text{PO}_4$, was followed by a decrease in the rate of excretion of CO_2 , the min. rate being reached after 30 min.; then by a sharp rise; a second fall was followed by a second max., the entire series of changes requiring about 3.5 hrs. In each part of the experiment a max. rate of excretion of CO_2 was accompanied by a min. in the curve for O_2 consumption. A soln. made up to contain the salts found in 150 g. beef caused upon injection a rapid rise in CO_2 excretion, the max. being attained in 1 hr.; the subsequent fall was accompanied by a rise in the consumption of O_2 . Since the rate of O_2 consumption decreases after the administration of certain hormones, the effect of the hormone is equiv. to a decrease in acidity in the organism. The reaction of the acid salt with bicarbonate accounts for the greater rate of elimination of CO_2 and for the alk. of the urine.

P. Y. JACKSON

Experimental rickets. P. M. HOLST. *Norsk. Magaz. Ingervidenskaben* 88, 1011-24 (1927); *Ber. ges. Physiol. exptl. Pharmacol.* 44, 529.—A diet of polished rice, oat groats or of rice, oat or wheat flour always leads to rickets, while rice or wheat starch and water cause only osteoporosis. The addn. of wheat or oat groats to a pure starch diet causes rickets. Rickets is, therefore, produced not by avitaminosis but by a toxic substance. The latter may be extd. from oat flour by prolonged boiling with 0.5% HCl . It is probably an org. compd. dialyzable and insol. in alc., since neither the ash nor the non-dialyzable portion of oat flour causes rickets, while the dialyzate and the alc. ppt. do. Rats kept in the dark on a diet free from vitamin A and D with a sufficient Ca supplement did not get rickets. Addn. of Ca lactate prevented rickets in rats kept in the light on a corn-wheat or oats-wheat diet. H. agrees with Mellanby that $\text{Ca:P} < 1$ is pathologically significant.

MARY JACOBSEN

The influence of quantity of food on growth. H. VON HOESSLIN. *Z. Biol.* 85, 175-94 (1926).—An expt. is made which extends over 400 days on 2 pure-bred puppies of equal initial weight on a mixed diet. One dog received $\frac{1}{3}$ the amt. of food given to the other. The increase in weight of the former was only 26% that shown by the latter.

F. K.

Iron metabolism. II. Iron and hemoglobin formation. WOLFGANG LINTZEL. *Z. Biol.* 87, 97-106 (1928).—An "Fe-free" diet of egg white, lard, sucrose, rice and vitamins, with and without FeCl_3 , or ox-blood was fed to young rats. It was found that the inorg. Fe was utilized both in the formation of hemoglobin, and also in the increase of total body Fe. Fe from ox-hemoglobin had no effect. **III. Observations with animals kept in rarefied air.** *Ibid* 137-44.—Rats, kept for 1 to 5 weeks in rarefied air of 280 mm. (corresponding to a height of 8000 m.) and on a mixed diet, showed a decrease in body weight, an increase in hemoglobin to 100%, an increase in total Fe and wt. of the heart. No further increase in Fe content took place after 3 weeks at this low pressure. Acclimatization was complete.

FRANCES KRASNOW

The influence of nicotine and caffeine on the growth of chickens. CHARLES E. CHASE. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 81, 469 (1927).—Caffeine fed to chicks retarded their growth. Nicotine in large doses at first stimulated growth and later retarded it.

J. F. LYMAN

Determination of the vitamin B requirement of the pigeon and its bearing on the theory of vitamin B function. GEORGE R. COWGILL AND B. H. KLOTZ. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 81, 470 (1927).—Vitamin B requirement of the pigeon is in linear relationship to the $\frac{1}{3}$ power of its body wt. $\text{Vitamin} = K W^{\frac{1}{3}}$. This formula holds for the rat and dog also. K is a const. characteristic for the species.

J. F. LYMAN

Some effects upon the young of inadequate maternal diets. I. Polyneuritis and hemorrhages. C. ULYSSES MOORE, JESSIE L. BRODIE AND ROBERT B. HOPE. *Univ. Oregon. Am. J. Physiol.* 82, 350-7 (1927).—On a diet of casein 18, salt mixt. 4, crisco 3, cod-liver oil 2, dextrin 71 and yeast 2%, normal growth and reproduction of rats

occurred but 73% of the young were lost during the nursing period. Some of the symptoms noted were: cerebral and visceral hemorrhages in young dying within the first week; myelin degeneration of the sciatics, vagi and other myelinated nerves and visceral and intra-cranial hemorrhages in young dying during the third week of life. The addition of lemon juice to the mothers diet had no effect; but an increase in the yeast content from 2 to 7% decreased the mortality of the offspring to 9.3%, practically eliminated the paralysis and greatly lessened the hemorrhagic condition. J. F. L.

The determination of the surface area of women and its use in expressing basal metabolic rate. HANNAH S. BRADFIELD. Univ. Mo. *Am. J. Physiol.* **82**, 570-6 (1927); Univ. Mo. Agr. Expt. Sta. *Research Bull.* **109**, 5-31.—The surface area of 47 women subjects was measured by means of the Elting surface integrator. The results obtained averaged the same as those obtained by the Worner linear formula; they were 6% below those obtained by the Du Bois linear formula, and nearly 2% below those obtained by the Du Bois height-wt. formula. Basal metabolism detns. on 16 of the subjects indicated that the Krogh modification of the Anb-Du Bois standards should be used for the prediction of basal metabolism of women. J. F. LYMAN

The protein intake of medical students. HOWARD H. BEARD. Western Reserve Univ. *Am. J. Physiol.* **82**, 577-9 (1927).—Male medical students (av. of 400) excreted 11.16 g. urinary N per 24 hrs., corresponding to 76.7 g. protein per 70 kg. body wt., after adding 10% protein lost in the feces. J. F. LYMAN

The digestion of cellulose in the wild rat. R. S. ALLEN AND J. J. CARLSON. Univ. Chicago. *Am. J. Physiol.* **82**, 583-90 (1927).—Ground Celotex (insulating lumber made from the residual material of sugar cane) was fed to wild rats, either without other food or mixed with food to the extent of 50 or 67%. In all cases the animals receiving Celotex died of starvation or enteritis. Enzyme prepns. from the animal digestive tract had no digesting effect on Celotex *in vitro*. Celotex has no food value, on the contrary it is harmful if ingested in large amts. J. F. LYMAN

A study of the laxative action of wheat bran. GEORGE ALBERT WILLIAMS. Yale and Jefferson Medical College. *Am. J. Physiol.* **83**, 1-14 (1927).—Wheat bran from which the water-sol. portion had been removed was laxative when added to the rations of dogs. The min. effective daily dose was 2% of the food intake. Crude fiber prep'd from bran was much more laxative, gram for gram, than was the washed bran. Crude fiber of bran, therefore, is an important contributory factor to the laxative effect of the bran. J. F. LYMAN

Blood regeneration in severe anemia. X. Assimilation and conservation of bile pigment, blood hemoglobin and muscle hemoglobin. G. H. WHIPPLE AND F. S. ROUSCHERT-ROBBINS. Univ. Rochester. *Am. J. Physiol.* **83**, 60-75 (1927); cf. *C. A.* **21**, 2494.—Dogs with exptlv. induced secondary anemia utilized for new red cell formation 80 to 90% of the blood hemoglobin introduced intraperitoneally or intravenously, while only 5 to 20% of that ingested by mouth was so utilized. When a pancreatic digest of dogs red blood cells was given intravenously 40% of the original hemoglobin was rebuilt into new hemoglobin. The results with muscle hemoglobin were not definite because of its poor toleration and low renal threshold. It is probably utilized. There was no evidence that bile pigment can be utilized in the anemic animal to form new red cell hemoglobin. **XI. Iron effect separated for organ effect in diet.** F. S. ROUSCHERT-ROBBINS AND G. H. WHIPPLE. *Ibid.* 76-83.—The addition of Fe salts to the diet of a dog in which anemia had been exptlv. produced sometimes did and sometimes did not result in an increased hemoglobin production and red cell output. This probably depended on an actual Fe shortage which might be present or absent. Addition of pig kidney or liver to a ration rich in Fe salts caused the expected increase due to kidney or liver and this increase was superimposed on the level of the Fe diet. J. F. L.

The anemia of rice disease. The effects produced by the addition of betaine hydrochloride, lactose, vitamins A and C, magnesium sulfate or mineral oil to the polished rice diet of pigeons. O. S. BARLOW. Western Reserve Univ. and Univ. Chicago. *Am. J. Physiol.* **83**, 237-44 (1927).—The administration of loosely bound HCl (betaine HCl) or butter or orange juice did not prevent the depressing effects of rice disease on body wt., respiration, temp. and red corpuscle counts. Lactose, mineral oil or MgSO₄ seemed to prevent the anemia without affecting the other effects. The beneficial action may be on the intestinal flora and consequent diminution of bacteremia. J. F. LYMAN

Experimental cretinism. II. The influence of the thyroid gland on the production and control of experimental rickets. M. M. KUNDE AND L. A. WILLIAMS. Univ. of Chicago. *Am. J. Physiol.* **83**, 245-9 (1927); cf. *C. A.* **22**, 3216.—No amt. of cod-liver oil added to a rickets-producing diet was adequate to prevent the development of rickets in cretin rats. J. F. LYMAN

Nature of the foodstuffs oxidized to provide energy in muscular exercise. I. In the normal animal. DAVID RAPPORT AND ELAINE P. RALLI. Western Reserve Univ. *Am. J. Physiol.* **83**, 450-65(1928).—Dogs on normal, high carbohydrate and high fat diets worked on a horizontal tread mill while records of their gaseous exchanges were made. It is concluded that even in mild exercise of short duration fat is utilized to supply energy for muscular work by its oxidation. J. F. LYMAN

A dietary deficiency canine disease—further experiments on the diseased condition in dogs described as pellagra-like by Chittenden and Underhill and possibly related to so-called black tongue. FRANK P. UNDERHILL AND LAFAYETTE B. MENDEL. Yale. *Am. J. Physiol.* **83**, 589-633(1928).—Fresh butter fat was effective in curing the disease in dogs described by Chittenden and Underhill (*C. A.* **12**, 286) and having a resemblance to pellagra in man. Egg yolk, boiled unpeeled carrots, lard, ext. of carrots and cryst. carotin were all potent in curing the disease. Cod-liver oil was ineffective; and yeast did not protect against the disease. It is suggested that naturally occurring pigmentary substances in foodstuffs play a role in nutritive processes. J. F. LYMAN

The influence of a vitamin-B-free diet on the growth of the Jensen sarcoma in rats. BRUNO HEYMANN AND ALFRED GALLINEK. Univ. Berlin *Centr. Bakt. Parasitenk. J. Abt.* **106**, 73-87(1928).—Young male rats subcutaneously inoculated with the Jensen sarcoma gave 80% of takes on a normal diet, and 56% on a vitamin-B-free diet. Of the tumors produced, 9% reached 10% of the body wt. within 30 days on the avitamin B diet, and 77% on a normal diet. The av. wt. of a tumor became 3.8 times greater on a normal than on an avitamin B diet. JOHN T. MYERS

Pellagra-like lesions associated with deficiency of vitamin B₂ in the rat. G. MARSHALL FINDLAY. Imperial Cancer Research Lab., London. *J. Path. Bact.* **31**, 353-64(1928).—Vitamin B consists of 2 parts: B₁ which is thermolabile and B₂ which is thermostable. Rats on a diet lacking B₁ behave like those which lack B; there is failure of growth, loss of appetite, decreased body temp., polyneuritis and death in about 5 weeks. The histological changes are those of inanition. Rats on a diet lacking B₂ show failure of growth, and as a terminal feature, loss of appetite and fall in temp. but no polyneuritic symptoms. After 8 to 10 weeks pellagra-like lesions appear on skin and buccal mucous membrane, followed by death 2 or 3 weeks later. The cardiac end of the stomach is papillomatous. The histological changes are those of inanition. There is hypertrophy of the adrenals with a deficiency of either B₁ or B₂ with a histological picture of slight toxemia or of the effects of cold. JOHN T. MYERS

Utilization of activated foods in animal pathology and in zoötechny. L. AUGER. *Compt. rend. soc. biol.* **98**, 972-3(1928).—Rations of the common grains, farina and powdered meat were subjected to the rays of the Hg vapor lamp and then fed to dogs with rickets, swine with osseous cachexia, horses with osteitis and to healthy fowls. Recovery was more rapid in dogs and swine than in controls receiving the same food non-irradiated. With horses the recovery was slow but definite. The fowls receiving the irradiated ration laid 128 eggs compared with 63 by the control flock. L. W. R.

Basal metabolism in adenoid patients. AL. POP AND N. POPOLITZA. *Compt. rend. soc. biol.* **98**, 1081-2(1928).—The development of adenoids in 20 cases was accompanied by a fall in the basal metabolism in 45%, a rise in 20% and in 30% the basal metabolism remained normal. After removal of the adenoids the basal metabolism became normal in all cases. L. W. RIGGS

Metabolism of sugars in the normal state and during starvation. G. MOURIGUAND AND A. LÉVILLIER. *Compt. rend. soc. biol.* **98**, 1110-3(1928).—The glycogen content of the liver ranged from 0.14 to 12.86% in the normal guinea pig and from 0.15 to 1.34% in the starved animal. In the muscles the ranges were 0.07 to 1.52% and 0.097 to 0.48% in the normal and starved animals, resp. The glucemia of the normal animals was fairly const. while that of the starved animals ranged from 0.85 to 1.38 parts per 1000. L. W. RIGGS

Summit metabolism during gestation and lactation. X. CHAHOVITCH AND (MLLB) M. VICHNITCH. *Compt. rend. soc. biol.* **98**, 1152-3(1928).—The results of a study of the energy metabolism of rats showed that the summit metabolism is notably diminished during gestation. After delivery the summit metabolism returns to the normal figure during lactation. The basal metabolism sometimes shows a slight diminution during gestation, followed by a gradual increase which is strongly increased during lactation. L. W. RIGGS

Physiologic action of vitamin B. Circulatory and respiratory phenomena. MARIE SKARZYNSKA-GUTOWSKA. *Compt. rend. soc. biol.* **98**, 1375-6(1928).—A study with dogs indicated that the exts. of vitamin B probably act by virtue of the choline, histamine and K salts which they contain. L. W. RIGGS

Irradiated sterols. RENÉ FABRE AND HENRI SIMONNET. *Compt. rend. soc. biol.* 99, 193-5(1928).—Curves are shown representing ultra-violet absorption of an alc. soln. of ergosterol, 1 to 10,000, before and after irradiation for 10, 20 and 30 min. The irradiated sterol had an activity of the order of 0.01 mg. per rat per day. After a certain amt. of irradiation the degree of antirachitic activity does not increase although the optical density gradually diminishes. L. W. RIGGS

Basal metabolism of inhabitants of Salta Province. P. MAZZOCCO. *Compt. rend. soc. biol.* 99, 237-8(1928).—Although the province of Salta (Argentina) is in a tropical latitude, its climate is temperate. The basal metabolism of its inhabitants is equal to that of persons living in cooler regions. L. W. RIGGS

The ketogenic diet. M. G. PETERMAN. *J. Am. Med. Assoc.* 90, 1427-9(1928); cf. *C. A.* 19, 1294.—The ketogenic diet as a means of treatment of epilepsy has been on trial for over 3 years. A period of fasting until convulsions have ceased, if practicable, is followed by the immediate diet prescription. This consists daily of not more than 15 to 20 g. of carbohydrate and 1 g. of protein per kg. of body wt. and the remaining caloric requirement is made up with fat. After 3 months' freedom from seizures the daily carbohydrate is increased 10 g. each month. From 6 to 9 months later the carbohydrate increases are alternated with 10 g. increases of protein. Twelve months after the seizures have been under control, the reduction of fat may be started. Slight variations are allowed according to the body wt. response. L. W. RIGGS

The vitamin B requirement of the calf. S. I. BRECHDEL. *Penn. Agr. Expt. Sta., Bull.* 213, 16-7(1927).—The effect of a vitamin-A-deficient ration upon the uterine development of calves is being studied. There is evidence to show, through blood studies, that the inability of the heifers to lactate on the ration deficient in vitamin B was probably due to an insufficient amt. of alkali-carrying roughages in the ration. Investigations will be made to det. whether this acidosis condition bore a direct relation to the ration used and was the sole cause of inability of the heifers to lactate upon the ration. E. A. SNYDER

Beriberi columbarum. R. McCARRISON. *Indian Med. Research Memoirs* No 10 (1928).—A condition—*beriberi columbarum*—having all the pathological characters of human beriberi has been produced under exptl. conditions in pigeons by means of diets of similar composition to those in use by human sufferers from the disease. This condition differs from *polyneuritis columbarum* in certain regards of which hypertrophy of the heart is the chief. The basal factor in the production of *beriberi columbarum* is insufficiency, but not complete want, of vitamin B (or of the antineuritic fraction of this vitamin). There is an optimum degree of insufficiency of vitamin B at which *beriberi columbarum* is most likely to arise; this optimum is provided by diets of which the vitamin B value is 20-50% below the min. required for the maintenance of normal metabolism. The ultimate cause of the disease is not the negative factor of vitamin-insufficiency but a positive and toxic agent produced in the course of a disordered metabolism arising out of insufficiency of vitamin B in the food. The clinical and pathological manifestations of beriberi are due in whole or in part to this specific agent. The existence of this agent has been demonstrated on pathological grounds and by statistical examn. of the exptl. data. *Beriberi columbarum* and *beriberi hominum* are preventable by the same means. Since *beriberi columbarum* can be produced by diets of similar composition to those in use by the subjects of *beriberi hominum*, since the pathological features of the two states are to all appearances the same, and since both are preventable by the same means, it is inferred that the etiology of the two conditions is the same. Expts. on animals suggest that beriberi-like maladies may be of different kinds: some due to infectious causes; some due to dietetic causes; and some due to a combination of both. The variety of "beriberi" dealt with here is due to dietetic causes; it is believed to be the variety which is endemic in certain parts of the Madras Presidency. The results of this investigation confirm the generally accepted view that endemic or true tropical beriberi is due to insufficiency of vitamin B (or the antineuritic fraction of this vitamin) and not to toxic substances produced in rice by bacterial action. They do not preclude the possibility that other maladies included under the generic term "beriberi" may have a different etiology. H. G. WELLS

Mineral nutrition of the living cell and vitamins—mineral nutrition and natural resistance of vegetables and animals to infectious diseases. M. P. MAZUR. *Ann. inst. Pasteur* 41, 948-81(1927).—A review of the author's work in this field, together with a summary and his conclusions; included is a review of the work of others. E. W. W.

Observations on calcium deficiency as a cause of certain diseases of animals and man. C. E. CORLETT. *Med. J. Australia* 1, 198-213(1928).—Ca or P deficiency or both can cause nervous disorder closely resembling that produced by deficiency of

vitamin B. It is, or may be, implicated in many morbid conditions of man and animals in which nervous symptoms often occur. Among these are polyphagia, earth-eating (and "sand disease"), bone-chewing, coprophagia, "ergotism," "lathyrism," scrapie or trotting disease of sheep, epizootic stringhalt, laminitis, rickets, osteomalacia, spasticity, paraplegia, tetany, milk fever and lactational dyspepsia of cattle and other animals, and the *stijfziekte* and *lamziekte* of South African cattle, and conditions answering to the same elsewhere. To these may be added some cases of supposed forage poisoning.

R. C. WILLSON

Cereal foods: their advantages and dangers. WM. WESTON. *Southern Medical J.* 20, 765-9 (1927).—When wheat, oats, yellow corn and rice are evaluated on a basis of fat, carbohydrate, protein, mineral and vitamin content, it is found that each has certain advantages and disadvantages, but that if used in combination as whole grains the result will show such a compensation that comparison with a single whole grain cereal is decidedly to the disadvantage of the single cereal, although it may have been grown under ideal conditions. A mixture of 35% wheat, 25% oats, 15% yellow corn and 25% brown rice was prepd., each cereal being selected from the section where conditions were such as to produce the highest mineral values, with the precaution that each of the mineral elements should be represented as well as an abundance of the amino acids, tyrosine, tryptophan and lysine. Feeding this mixt. resulted in prompt stimulation of appetite, prompt and progressive increase in weight, increase in 4 days of transitional cells and platelets, increase in 7 days of polymorphonuclear neutrophils and corresponding decrease in lymphocytes and in 10-12 days a progressive increase in hemoglobin. Lactating animals, both human and lower, were fed with the single whole grain cereals and with the mixt. of the 4 whole grain cereals. There was a much quicker and more permanent effect in increase of quantity and improvement of quality of the milk as reflected in the growth and development of the young. I and lysine were furnished by using a brown rice that had been grown near the sea. R. C. WILLSON

Cod-liver oil (BAILEY, *et al.*) 27.

F—PHYSIOLOGY

F. K. MARSHALL, JR.

New investigations on the glycolysis in blood in vitro. G. B. TAFURI. *Arch. sci. biol.* (Italy) 11, 71-6 (1928).—Sterile dog blood was defibrinated and then suspended in equal vols. of (1) isotonic NaCl soln., (2) equal vols. of blood serum and (3) equal vols. of phosphates (p_H 7.4); and the power of these solns. to reduce sugars was measured. The % sugar reduced in the 3 cases are 7.0, 8.8 and 18.9, *i. e.*, phosphates are most effective. In another series the defibrinated blood was hemolyzed with distd. H_2O . In this case isotonic NaCl soln. added did not give the mixt. power to reduce sugar; however, phosphate and $NaHCO_3$ (both at p_H 7.7) did cause sugar reduction. Therefore, the proteins of the plasma are not necessary in glycolysis but only the presence of certain electrolytes, *i. e.*, phosphates and bicarbonates in suitable concn., which assist the special enzymes contained in the blood corpuscles.

A. W. CONTIERI

Hyperglycemia by blood-letting. II. Relation between pressure and glucemia in bleeding. A. AGGAZZOTTI. *Boll. soc. ital. biol. sper.* 2, 863-9 (1927).—Three cases were studied: bleeding alone, bleeding after cutting the vagus and after injection of Witte peptone in physiol. soln. In each case, the viscosity of the blood drops regularly, while that of the serum is almost const. or drops slightly. The blood pressure remains fairly high and only drops rapidly at the last stages of bleeding, even when the blood pressure has been lowered at the start by use of the peptone. In all cases the sugar in the blood and serum increases; *i. e.*, 346% in the first case, 200% in the second case and 250% after injecting Witte peptone. It appears, therefore, that the increase in sugar content is not directly proportional to the drop in blood pressure; in fact, the blood pressure remains quite high right to the end, showing that there must be a copious secretion of adrenaline which tends to maintain the pressure. It is more probable that the increase in sugar is proportional to the blood lost, the big rise coming in the first case when blood to the extent of 2.2% of body wt. was lost, in the second when 3.8% was lost and in the third when 4.2% of body wt. of blood was lost. **III. Adrenaline and glycogen. Content in the liver and muscles before and after bleeding.** *Ibid* 870-5.—The glycogen content in the liver and muscle of a guinea pig was detd.; then the animal was bled to death and glycogen detd. again. There is a marked decrease in the amt. in the liver, with a corresponding increase in the muscles, showing that in bleeding adrenaline is liberated which causes a more intense change of glycogen into glucose. **IV. Influence of the suprarenal capsule on the splanchnic nerve.** *Ibid* 875-81. **V. Topography**

of hyperglucemia by blood-letting. *Ibid* 881-3.—The amt. of sugar in blood from various parts of the body has been detd. in a no. of dogs before and after bleeding. Though the av. sugar content is 1.16% of the total amt. of blood, the sugar found after bleeding at the carotids was 2.59%, cava superior at liver 4.95%, cava inferior at liver 2.42%, portal cavity 2.57%, renal vein 2.08%, iliac vein 2.12%, left ventricle 2.82%, right ventricle 2.85%. It is evident that the liver is the source of the sugar, although, particularly when food is present, the intestines are a secondary source of supply. A. W. C.

Studies on blood of overworked animals. I. Variation of the electrolytes. OSCAR M. BERMARDI. *Boll. soc. ital. biol. sper.* **2**, 895-7 (1927)—A dog under influence of narcotics which have been found not to affect the ionic equil. of blood was connected with an elec. current so as to stimulate the muscles on one side and samples of blood were taken after several hours stimulus. The blood was then analyzed. Na and Mg were found to diminish, while K, Ca, Cl and inorg. P increased. These same elements were detd. on the dry residue of samples of blood as well. In the latter case, Cl, Na and Mg decrease P (inorg.) increases, and Ca and K fluctuate so as to appear meaningless. Decrease in Cl agrees with observations of Aggazzotti who noted Cl decrease in a man after long marches on high mountains, while increase in inorg. P is logical from what is known of the metabolism of this element. A. W. CONTIERI

Effect of ligature of pancreatic ducts on the regulation of the glycogen titer. S. CACCURI. *Boll. soc. ital. biol. sper.* **2**, 918-22 (1927)—The pancreatic ducts of 4 dogs were ligated and every 15 days dextrose soln. was injected by way of the jugular vein and the free and combined sugar was detd. Two dogs died, but in the remaining after 75 to 90 days it was found that after injection of sugar the combined sugar increased while free sugar diminished, i. e., similar results as would result from insulin injection. Apparently, a tolerance for sugar is gradually acquired. The pancreas was found atrophied and changed almost wholly to connective tissue. A. W. CONTIERI

Influence of the spleen on the regulation of the glycogen titer. A. FRANCAVIGLIA. *Boll. soc. ital. biol. sper.* **2**, 922-4 (1927)—The free and combined sugar of the blood of 12 rabbits was detd. before and after splenectomy. Changes in sugar appear soon after removal and persist for 8-10 days before returning to normal. Injection of glucose soln. after splenectomy leads to a lowering in free sugar and an increase in the combined sugar. A. W. CONTIERI

The elimination of cholesterol in the urine. LUIGI COSTORELLI. *Chim. med. gen. e semeiotica Napoli. Polidimico sez. prat.* **33**, 179-98, *Chem. Zentr.* **1927**, 1, 1181—The work of Gardner and Gainsborough (*C. J.* **19**, 3526) is investigated, these authors not having considered sufficiently the difficult hydrolysis of cholesterol oleate. The latter must be boiled for a time with EtONa to bring about complete decomposition. The existence of esters of cholesterol sulfuric acid is not proved conclusively by G. and G. Expts. by C. indicate that the quantity of cholesterol in urine is related in some way to the blood cholesterol: blood fatty acid ratio. C. C. DAVIS

The nitrogen excretion of camels. HOMER W. SWIFT AND H. SILVERSTEIN. Univ. Virginia. *J. Biol. Chem.* **78**, 409-11 (1928)—The distribution of the N partition products in the urine of the Bactrian camel (*Camelus bactrianus*), the dromedary (*Camelus dromedarius*), the llama (*Lachenia huanacas*), and the alpaca (*Lachenia vicugna*) was the same as with other herbivora. Like results were found with a pregnant camel. Urea was in amts. of 55.69%, uric acid 0.3-1.8%, NH_3 1.7-4.5% (except in 2 cases), amino acid 0.2-2.1%, creatinine N 4.6-14.4%, creatine N 0.7-6.9%, and undetd. N 12.7-28.3%. These results are in contradiction to those of Read (*cf.* *C. J.* **19**, 3129). H. J. DEUEL, JR.

Observations of the rennin coagulation of milk. Effect of hirudin, of heparin, of cephalin and of fat removal. J. B. STONE AND C. L. ALSBERG. Stanford Univ. *J. Biol. Chem.* **78**, 557-72 (1928)—Hirudin and cephalin were both without influence on the rate of milk coagulation by rennin. Some preps. of heparin strongly inhibited the coagulation of milk while others were inactive. There is, therefore, no evidence that the inhibition of blood coagulation is related to the inhibition of milk coagulation. The active heparin preps. acted on the rennin rather than on the milk. The extn. of fat and lipid from the rennin soln. and allowing it to stand satd. with ether did not affect the coagulating power. Et₂O, EtOH and CHCl_3 inhibit the rennin coagulation of milk when present in the milk in sufficient quantity while benzene and petroleum ether are less effective. The effect is not due to a lowering of surface tension since saponin which does this is without influence on the coagulation. Neutralized soap soln. delays the coagulation, probably because of the removal of Ca since addn. of CaCl_2 prevents the effect. Milk skimmed by a separator coagulates less rapidly than gravity-skimmed milk. H. J. DEUEL, JR.

The rate of lactic acid formation in muscle contraction. G. EMBDEN AND E. LEHNARTZ. *Z. physiol. Chem.* **176**, 231-48(1928); cf. *C. A.* **21**, 2138.—The objections raised by Meyerhof (*Klin. Wochschr.* **6**, 1219) and by Meyerhof and Schultz (*C. A.* **22**, 108) that the high ratio of increase in lactic acid of frog muscle during stimulation in N to the lactic acid consumed during stimulation in O, as reported in the author's previous paper, are met by further expts. The contention that the semimembranous muscle is unsuitable for such expts., because its thickness does not allow rapid diffusion of O to the interior, is invalidated by similar results now reported with the sartorius muscle. The ratio is much higher than Meyerhof's oxidation quotient. The conclusions drawn in the author's previous paper are fully upheld. A. W. DOX

The action of extracts of mesenteric lymph glands on leucocytes. R. H. MOLE. *J. Path. Bact.* **29**, 107(1926); *Physiol. Abstracts* **13**, 17.—A saline ext. was prepd. from the mesenteric lymph glands of splenectomized rabbits. It produced a polymorphonuclear leucocytosis on injection into splenectomized rabbits, but no effect on normal rabbits. H. G.

Studies of the chemical mechanism of hydrochloric acid secretion. I. Electrolyte variations in human gastric juice. H. A. BULGER, C. M. STROUD AND M. L. HEIDEMAN. Washington Univ. *J. Clin. Investigation* **5**, 547-60(1928).—Relatively little change in the concn. of Cl in human gastric fluid attends acid secretion, but the total base falls proportionally to the increase in acid. The concn. of PO_4^{---} in gastric contents is usually greater than in serum, even when stimulation results in no HCl secretion. When much acid is produced, the concn. of PO_4^{---} falls. II. Observations on the blood passing through the stomach of dogs. H. A. BULGER, D. ALLEN AND L. B. HARRISON. *Ibid.* 561-71(1928).—As blood flows through a secreting portion of a dog's stomach, the total base increases while the Cl⁻ undergoes little change in concn. In gastric secretion, therefore, Cl⁻ leaves the blood with H_2O with retention of base which is neutralized in turn by HCO_3^- and organic salts. ARTHUR GROLLMAN

Role of oxidation in maintaining the dynamic equilibrium of the muscle cell. A. V. HILL. Univ. of London. *Proc. Roy. Soc. (London)* **B103**, 138-62(1928).—The resting heat rate of the sartorius muscle of the frog in O_2 agrees with the consumption of O_2 ; it is decreased by survival in O_2 , and by stimulation followed by recovery in O_2 . In the absence of O_2 , the min. resting heat rate is attained within 0.5 hr. in N_2 and is explained by production of lactic acid; it is increased immediately by stimulation (including electrocution or excessive elec. stimulation); and this increase may persist for many hrs. and may reach a high value with advanced fatigue. The increase is not due simply or mainly to increased formation of lactic acid, or to increased acidity of the tissues; other anaerobic catabolic changes occur. These effects of anaerobic stimulation are partially or completely reversed by recovery in O_2 . J. S. H.

Absolute value of the isometric heat coefficient T_1/H in a muscle twitch, and the effect of stimulation and fatigue. A. V. HILL. Univ. of London. *Proc. Roy. Soc. (London)* **B103**, 163-70(1928).—The isometric heat coeff. T_1/H has a mean value 6.16. The decompn. of phosphagen, a labile compd. of creatine and phosphate, and the accompanying production of heat apparently occur in a different manner *in vitro* and *in vivo*. JOSEPH S. HEPBURN

Absence of delayed anaerobic heat in a series of muscle twitches. A. V. HILL. Univ. of London. *Proc. Roy. Soc. (London)* **B103**, 171-82(1928).—In the absence of O_2 , the initial and the total heat production of a muscle twitch are very nearly equal. Therefore, little or no delayed anaerobic heat production and lactic acid formation occur. Lactic acid is produced entirely during contraction and relaxation. J. S. H.

Recovery heat production in oxygen after a series of muscle twitches. A. V. HILL. Univ. of London. *Proc. Roy. Soc. (London)* **B103**, 183-91(1928).—Measurement was made of the total heat set free as the result of a series of muscle twitches in O_2 and of a similar series in N_2 . The ratio of the heat in O_2 to the heat in N_2 had a mean value of 2.07. The oxidative quotient for lactic acid was found to be 4.81. The isometric heat coeff. of a muscle twitch was the same in O_2 and in N_2 ; therefore, the initial heat is entirely non-oxidative in nature. JOSEPH S. HEPBURN

The osmotic pressure of the contents of the vagina. F. WITTENBERG. *Arch. Gynakol.* **133**, 193-210(1928).—The osmotic pressure of the contents of the vagina varied between 4.27 and 18.46 atm. while that of the blood averages 7.72. The vaginal contents occasionally were isotonic with the blood, usually hypertonic but quite often hypotonic. HARRIET F. HOLMES

The state of calcium in the serum during the period of gestation. O. BOKELMANN AND A. BOCK. *Arch. Gynakol.* **133**, 308-30(1928).—In pregnancy there is a slight decrease in the total Ca content of the blood serum. At the onset of delivery the Ca

concn. in the serum is relatively high, but at the close of delivery returns to the low level of the last half of pregnancy and then slowly rises during the puerperium without reaching its former level. The diffusible Ca shows a fairly uniform relative increase during pregnancy. An abs. increase of concn. occurs only at the end of pregnancy and onset of delivery. At the close of delivery low values are found which gradually increase during the puerperium.

HARRIET F. HOLMES

The colloid structure of the plasma during gestation. I. The colloid stability of the plasma during the normal period of gestation. H. EUFINGER. *Arch. Gynäkol.* 133, 452-64(1928); cf. *C. A.* 22, 2612.—By the use of the Gerloczy reaction for stability it was shown that the colloid stability of the plasma decreases as pregnancy advances and reaches its lowest point during the puerperium. The increased lability of the colloids of the plasma during normal pregnancy indicates a measure of defense of the organism at this much threatened period as with increase in lability the power of the colloids to act as protective colloids is increased. II. The protein blood picture in pregnancy. H. EUFINGER AND R. SPIEGLER. *Ibid* 133, 465-74.—The total protein content of the blood serum is decreased in the last months of pregnancy and in the puerperium. There is a shifting of the proteins in the direction of the phases of coarse dispersion. There is a change in the albumin-globulin quotient, the globulins increasing at the expense of the albumins and euglobulin particularly showing a marked increase. The occurrence of an albuminuria in pregnancy and particularly *sub partu* is not an expression of an injury to the kidney but the indication of the elimination through the healthy kidney of non-utilizable protein material. III. The anchoring of cholesterol during the period of gestation. H. EUFINGER. *Ibid* 475-89.—In spite of a marked increase in total cholesterol during pregnancy, the cholesterol that can be removed directly from the serum by shaking with ether decreases as pregnancy progresses. Cholesterol, therefore, during pregnancy must be firmly anchored so only a relatively small part remains labile and easily removable. This changed anchoring of cholesterol depends on the colloidal changes in the serum in pregnancy. The amount of anchored cholesterol is dependent on the euglobulin present as protective colloid in the serum, so with high euglobulin content little cholesterol can be shaken out. The H₂O and salt content affect the labile cholesterol indirectly through their effect upon the proteins, particularly the euglobulin. IV. The biological significance for normal pregnancy of colloid alterations. H. EUFINGER. *Ibid* 490-503.—The changes in the colloidal structure of the plasma during pregnancy have an effect on the surface tension of the cells and tend to increase the permeability of the cell membranes which is responsible for the changed tonus of the blood vessels and the altered reaction of the blood vessels to vasoconstrictor substances such as adrenaline. The firmer anchoring of cholesterol in the serum is an important cause for the increased retention and altered excretion of cholesterol noted in normal pregnancy. Diuretic tests indicate that the pregnant organism is able to hold back the necessary mineral substances and thereby increase the ecucolloids of the blood. V. Colloid structure and the course of serological reactions. H. EUFINGER. *Ibid* 504-9.—In the toxicoses of pregnancy a direct v. d. Bergh reaction seems not dependent on the quant. correlation of the various proteins of the blood. However, there is a marked relation between a direct v. d. Bergh reaction and increased lability of the colloids and relative decrease of cholesterol of the blood. The delayed storing up of a dye like Congo red injected intravenously also seems dependent on the increased lability of the colloids acting as protective colloids. VI. The clinical symptoms of "Ödneklose" in their dependence on colloidal structure. H. EUFINGER AND R. SPIEGLER. *Ibid* 510-32.—The term "Ödneklose" was coined by I. Seitz to indicate the symptom complex of edema, nephrosis and eclampsia. The underlying basis for this condition is a general disturbance in the make-up of the colloids of the body and in many ways it seems related to the lipid nephrosis, unconnected with pregnancy. There is an excessive shifting of the colloids to the gel state, lipoiduria, edema and injury to the liver and kidney. The injury to the liver and kidney is secondary as there is not only an alteration of the cell colloids of these organs, but they are also the organs that receive and eliminate toxic products. One form of eclampsia, "lability eclampsia," is to be differentiated from "Ödneklose." "Lability eclampsia" is sudden in onset, edema is slight, lipoiduria is absent, there is seldom a direct v. d. Bergh reaction and colloid stability is high without shifting to the phase of coarse dispersion, a condition quite the reverse of "Ödneklose" but also probably dependent on alterations in the colloids of the body.

HARRIET F. HOLMES

The condition of the calcium of the serum in pregnancy. II. The relation between the mother and fetus. O. BOKELMANN AND A. BOCK. *Arch. Gynäkol.* 133, 739-46(1928).—The total Ca content and also the abs. concn. of dialyzable Ca are always

higher in blood from the umbilical cord than in the blood of the mother. The relative value of the dialyzable portion, however, is somewhat lower in the blood from the umbilical cord. The total Ca and the diffusible Ca are always higher in the blood from the Vena umbilicalis than in the blood from the Arteriae umbilicalis. The abs. Ca and the abs. concn. of diffusible Ca are higher in the Vena umbilicalis than in the venous blood of the mother. The passage of Ca from mother to fetus is not a case of simple diffusion through the placenta but probably involves active metabolic processes as well.

HARRIET F. HOLMES

Chemical and bacteriologic studies of the vaginal secretion in women at the menopause. R. KESSLER AND F. LEHMANN. *Arch. Gynäkol.* 133, 791-804(1928).—On the cessation of ovarian function the mucous membrane of the vagina does not show at once a diminished storage of glycogen, with a diminished acidity of the vaginal secretion and alteration in the vaginal flora, but the change to the atrophic vagina poor in glycogen is very gradual.

HARRIET F. HOLMES

Clinical studies of water and salt metabolism of pregnant women. J. BATISWEILER. *Arch. Gynäkol.* 134, 62-72(1928).—In the second half of pregnancy there is a distinct disturbance of H₂O metabolism as shown by the response to the H₂O test in which 1000 g. H₂O is ingested. The concn. of the urine is distinctly lowered for the first 12 hours. The ability of the kidney to concentrate the urine is retained and the lessened concn. is extrarenal in nature and is the result of the tendency to edema of the tissues in the latter half of pregnancy. The excretion of H₂O is normal or sometimes delayed. Administration of NaCl leads to a marked diuresis and to the excretion of the superfluous NaCl.

HARRIET F. HOLMES

The transportation and elimination of organic dyes by the animal organism. MILDRED R. ZIEGLER AND LAFAYETTE B. MENDEL. Yale Univ. *Am. J. Physiol.* 82, 299-317(1927).—Thirty-one dyes were injected intravenously into dogs, rats and rabbits; 24 were eliminated in the urine; 3 fat-sol. dyes, yellow AB, yellow OB and oil yellow, were conjugated and made water sol.; dinitroresorcinol and carmine, fat- and H₂O-insol. dyes, were the only ones not found in the bile. Amaranth, Martius yellow and methyl violet appeared in the pancreatic juice; none of the dyes was found in the saliva, even when the salivary glands were actively stimulated. Naphthol yellow S, crystal violet, methyl violet and ethyl violet stained the mucosa of the stomach and intestine; the cerebrospinal fluid was always free of dyes and leuco bases; the dyes were always found in the thoracic lymph; but never in the humors of the eye, unless the fluid had been previously withdrawn and allowed to reaccumulate, in which 5 of 7 tested stained the newly formed fluid.

J. F. LYMAN

Nerve metabolism. II. Respiration in oxygen and nitrogen. R. W. GERARD. Kaiser Wilhelm, Inst. of Biology, Berlin-Dahlem. *Am. J. Physiol.* 82, 381-404(1927); cf. C. A. 22, 454.—The O₂ consumption of resting frogs sciatic nerve continued const. for over 20 hrs. at 11 to 21 cm. O₂ per hr. per g. of nerve, av. 16 (winter *esculenta*) and 17 to 27, av. 23 (winter *temporaria*). Nerves from frogs taken in the spring gave higher values, 21 for *esculenta* and 28 for *temporaria*. Smaller nerves had a higher O₂ consumption than larger ones. Cutting or crushing a nerve or killing with CHCl₃ produced a temporary increase in O₂ consumption. Glucose and sodium lactate in small amts. had no effect; in larger amts. they inhibited respiration. KCN diminished but did not entirely abolish O₂ consumption. The temp. coeff., between 15° and 25°, was 2.2; the respiratory quotient for winter frogs was 0.77. A nerve stimulated continually practically doubled its resting metabolism. Intermittent stimulation, 22 secs. every 4 min., resulted in 3 times as much extra O₂ consumed as when stimulation was continuous. The respiratory quotient of the excess metabolism of activity was 0.97. The excess O₂ consumption did not appear and ceased sharply with stimulation but showed a lag of about 15 min., both to appear and disappear. A nerve kept in N₂ developed an O₂ debt. During 20 hrs. in N₂ a nerve produced about 10% as much CO₂ as during the same time in O₂. There seems to be present in nerves an oxidizing reserve which does not involve a lactic acid mechanism.

J. F. LYMAN

The regulation of respiration. XI. Effects of changes in alveolar oxygen pressure on tissue acidity and blood acidity. ROBERT GESELL AND ALRIK B. HERTZMAN. Univ. Mich. *Am. J. Physiol.* 82, 591-607(1927).—O₂ mixts. in N₂ were administered from rebreathing tanks by normal ventilation and by artificial ventilation. Changes in ventilation and O₂ consumption were recorded along with changes in acidity of the circulating venous and arterial blood, one MnO₂ electrode being placed in the external jugular vein and the other in the carotid artery. The results support the theory that augmented ventilation elicited by low alveolar O₂ is associated with increased intracellular acidity; that subsequent depression of ventilation from the administration

of room air is associated with a decreased intracellular acidity. **XII. The vagal reflex control of the respiratory movements of the isolated head. Peripheral mechanical and peripheral chemical factors.** ALRICK B. HERTZMAN AND ROBERT GESELL. *Ibid* 82, 608-20 (1927).—All connections between the head and trunk of an animal, except the vagi nerves, were severed; the head was kept alive, independent of the trunk, by connecting it in the circulation of a second animal. The severed trunk was kept alive by artificial respiration. The activity of the respiratory center of the isolated head was recorded through movements of the cricothyroid muscle which contracts with each movement of the lungs in the intact animal. The results support the significance of mechanical influences in eliciting reflex vagal effects on the respiratory center. The administration of CO_2 , of air low in O_2 and of NaCN to the isolated trunk produced inconstant and delayed reflex stimulation of the respiratory muscles of the isolated head. Similar administrations to the isolated head *via* the donor elicited prompt and constant stimulation of the respiratory movements in both the isolated head and the donor. J. F. LYMAN

The regulation of respiration. XIII. Effects of change in oxygen content of artificially administered gaseous mixtures on expired carbon dioxide and oxygen as studied with continuous electrometric methods. ROBERT GESELL AND DANIEL A. MCGINTY. Univ. Mich. *Am. J. Physiol.* 83, 323-34 (1927).—The results were in agreement with the theory of an acid mechanism of respiratory control. **XIV. The effects of hemorrhage and reinjection on expired carbon dioxide and expired oxygen as studied with continuous electrometric methods.** DANIEL A. MCGINTY AND ROBERT GESELL. *Ibid* 335-44.—Hemorrhage was found to give a prompt decrease in expired CO_2 and in retained O_2 . Reinjection momentarily increased CO_2 elimination, followed by a return to the prehemorrhage level. The period of CO_2 overshooting was accompanied by a corresponding over- O_2 retention which showed similar recovery to normal values. **XV. Effects of intravenous injection of sodium bicarbonate and sodium carbonate on expired carbon dioxide and expired oxygen as studied with continuous electrometric methods.** ROBERT GESELL AND DANIEL A. MCGINTY. *Ibid* 345-57. Na_2CO_3 intravenously administered caused decreased elimination of CO_2 and increased retention of O_2 , followed by gradual recovery. NaHCO_3 caused an increased elimination of CO_2 and increased retention of O_2 followed by gradual recovery. NaHCO_3 is thought to have a direct salt effect on the carbonate buffer system tending to drive CO_2 from the blood into the tissues and into the alveolar air. Na_2CO_3 increased the alkali of the cells. NaHCO_3 may temporarily increase the acidity. On that basis the respiratory movements associated with the administration of the salts may be explained by an acid mechanism. **XVI. The effect of intravenous injection of sodium cyanide on gaseous exchange and acid metabolism.** DANIEL A. MCGINTY AND ROBERT GESELL. *Ibid* 358-72.—The effects of NaCN on CO_2 elimination and O_2 retention varied somewhat. In general they appear to agree with an acid mechanism of respiratory control. J. F. L.

The regulation of respiration. XVII. Effects of intravenous injection of sodium cyanide on the acidity of the arterial and venous blood. ROBERT GESELL AND ALRICK B. HERTZMAN. Univ. Mich. *Am. J. Physiol.* 83, 421-34 (1928).—During normally controlled breathing the injection of 0.01 N NaCN was followed by an initial increased blood alkali, followed by progressively increasing acidity above the preinjection level. The final increased acidity varied from 0.04 to 0.4 μH . With constant artificial ventilation the initial alkali was missing and was replaced by increased acidity of the blood. The initial increased alkali was due probably to over ventilation of the lungs; the final increased acidity was due probably to a disproportionate increase in anaerobic metabolism over aerobic metabolism. The probability of increased cellular acidity resulting from disturbed oxidations and impaired acid transport support the view of the significance of intracellular acidity as a factor in control of ventilation. **XVIII. The effects of low and high alveolar oxygen and of sodium cyanide on the carotid and femoral flow of blood as studied with the continuous electrometric method.** THEODORE G. BERNTHAL, DETLEV W. BRONK, NARCISO CORDERO AND ROBERT GESELL. Univ. Mich. *Ibid* 83, 435-44 (1928).—The possibility of a central and peripheral acid mechanism of vol. flow control of the blood, modified by the paralytic action of reduced oxidation, is proposed. The results are not in disagreement with the view that metabolism of the vasomotor center may play a part in the control of vol. flow of the blood. J. F. L.

The effect of anoxemia on the size of the heart as studied by the x-ray. E. J. VAN LIERE. Univ. of Chicago. *Am. J. Physiol.* 82, 727-32 (1927).—Animals were placed in a steel respiratory chamber from which the air was partially exhausted (O_2 reduced to 2.5 to 8.7%), allowed to remain 3 to 4 min., immediately after which x-ray photographs of the heart were made. **Conclusion.**—Dogs, cats, rabbits and guinea pigs, subjected to anoxemia (2.5 to 8.7%), showed acute cardiac dilatation. J. F. L.

The total energy requirement of the albino rat for growth and activity. F. A. HITCHCOCK. Ohio State Univ. *Am. J. Physiol.* **83**, 28-36(1927).—The total food consumed by both mother and young during the first 30 days of life was 11.5 cal. per g. of gain for the control rats and 10.6 cal. for meat-fed rats (fed fresh meat once daily; otherwise fed like the controls). The control rats consumed 4271 cal. and the meat-fed rats 4197 cal. in doubling their birth rates. During the period from 30 to 90 days of age the caloric cost of one g. of gain was inversely proportional to the square root of the % increase in wt. The increase in food consumption due to physical activity was directly proportional to the cube root of the activity expressed in meters. J. F. L.

The metabolism of resting muscle. I. The respiratory quotient of resting muscle. HAROLD E. HIMWICH AND WILLIAM B. CASTLE. Harvard Univ. *Am. J. Physiol.* **83**, 92-114(1927).—The respiratory quotient of dogs muscle was detd. from the O_2 and CO_2 contents and capacities of arterial and venous blood. The av. corrected result for isolated muscles was 0.71 ± 0.10 ; for non-isolated muscles 0.77 ± 0.08 and for the expired air 0.80 ± 0.04 and 0.77 ± 0.03 , respectively, for the 2 groups. Resting muscle *in situ* oxidized, besides carbohydrates, either fat or protein or both, probably in the same proportions as does the rest of the body. The av. O_2 consumption of muscle per g. per hour in dogs weighing about 22 kg. was 0.36 cc. The O_2 consumption per g. of resting muscle is only 66% of that calcd. per g. of the entire animal. J. F. L.

Retention of intravenously injected fluid in fasting anhydremia and phlorhizin hydreemia. HENRY B. BARBOUR AND RAYMOND W. FRANKMANN. Univ. Louisville, Ky. *Am. J. Physiol.* **83**, 171-8(1927).—Dogs were fasted several days, inducing anhydremia, and fasted with phlorhizin, producing hydreemia. Glucose-free Locke's soln. was then introduced intravenously and its retention in the blood detd. through the sp. gr. of the blood. The introduced fluids were retained in the blood longer than in normally fed animals. **Conclusion**—The tissues of fasted animals, with or without phlorhizin, are less avid of intravenously injected fluid than during normal feeding. J. F. LYMAN

Activity. III. The influence of phosphate feeding on activity; the relation of blood sugar to activity. MARY SHIRLEY. Univ. of Minn. *Am. J. Physiol.* **83**, 377-83 (1928).—Phosphate feeding acted as a mild stimulant to spontaneous activity in the white rat. Correlation between blood sugar and activity seemed slightly negative. J. F. LYMAN

The respiratory response to carbon dioxide. PAUL PADGETT. Johns Hopkins. *Am. J. Physiol.* **83**, 384-94(1928).—When air containing an increased amt. of CO_2 was breathed, the max. increase in respiration occurred only after the mixt. had been breathed some time. There was no delay in raising the CO_2 content of the arterial blood. The lag in response of the respiration center to CO_2 is thought to be due to the time required to sat. the tissues (especially the respiratory center) to the new CO_2 tension. J. F. LYMAN

Phosphoric acid changes in worked mammalian muscle. LAURENCE IRVING. Stanford Univ. *Am. J. Physiol.* **83**, 395-405(1928).—Acid-sol. inorganic phosphates, organic phosphates, glycogen and lactic acid in muscles were detd. under various conditions. The agreement between lactacidogen, lactic acid and glycogen was excellent when the lactacidogen reduction of the worked muscle was distinct. In normal muscle there was no sign of agreement. J. F. LYMAN

The relationship of glycogen formation in the muscles to the pancreas and to adrenaline. YOUNG O. CHOI. Univ. Toronto. *Am. J. Physiol.* **83**, 406-14(1928).—When glucose was injected intravenously into eviscerated cats no change in the glycogen content of the leg muscles occurred. If insulin were injected simultaneously, or if the animals were not eviscerated, the injection of glucose was followed by an increase of glycogen in the muscles. The pancreas, therefore, is essential for the conversion of glucose to glycogen and for the storage of the latter in the muscles. Adrenaline did not stimulate the breakdown of muscle glycogen nor did it give rise to hyperglucemia in eviscerated cats. J. F. LYMAN

Calcium and ultra-violet irradiation. A. The effect of ultra-violet radiation upon serum calcium. B. Calcium utilization on a calcium-poor diet with ultra-violet radiation. LAWRENCE T. FAIRHALL. Harvard Univ. *Am. J. Physiol.* **84**, 378-85(1928).—Ultra-violet irradiation resulted in an increased Ca content of the blood serum both in dogs and rats. In rats on a low Ca diet ultra-violet irradiation increased the rate of growth to normal, but animals were produced which contained only about 50% as much Ca as normal animals. J. F. LYMAN

Muscular exercise under low barometric pressure. III. The output of carbon oxide. EDWARD C. SCHNEIDER AND ROBERT W. CLARKE. School Aviation Med.,

Mitchell Field, L. I., and Wesleyan Univ. *Am. J. Physiol.* **85**, 65-77(1928).—The vol. of CO_2 eliminated during phys. exercise was not changed by a reduction of barometric pressure; but the consumption of O_2 was decidedly lowered. This was probably caused by the "blowing off" of performed CO_2 when work is done at low barometric pressure.

J. F. LYMAN

Studies on the physiology of the hunger activity of the intestinal tract. V. Hunger contractions of the stomach in experimental hypothyroidism. A. G. KRATINOV AND F. N. KRATINOVA. *Zhurnal ekspl. biol. Med.* **8**, 561-8(1928).—Gastric activity is increased following thyroidectomy in dogs, and there is also evidence of strong bulimia. The gastric mucosa is edematous and there is an intensive mucus secretion.

S. M.

Minimum pressure of oxygen compatible with life. BEHAGUE, GARSIAUX AND CH. RICHEL FILS. *Compt. rend.* **186**, 1573-5(1928); cf. *C. A.* **21**, 2311.—Expts. with rabbits proved that there is a mean critical pressure for each percentage of O in the air breathed and that this pressure rises and falls with the percentage of O ; thus if the proportion of O ranged between 18 and 21% the fatal pressure was about 29 mm of Hg while if the percentage of O ranged between 61 and 89% the critical pressure was about 52 mm. of Hg. Under pressures below the critical the animal dies.

L. W. RIGGS

Simultaneous excitation of the external and internal secretions of the pancreas. E. GLEY AND R. HAZARD. *Compt. rend. soc. biol.* **99**, 16-8(1928); cf. Freud and Saadi-Nazim, *C. A.* **22**, 458.—Under the influence of pancreatic excitation due to secretin which is produced by the action of HCl on the duodenojejunal mucus, there is in general a secretion of insulin.

L. W. RIGGS

Buffer power of the saliva. A. D. MARENZI AND J. J. ROSSINGNOLI. *Compt. rend. soc. biol.* **99**, 176-8(1928).—Saliva has a slight buffer power as compared to that of the blood. The p_{H} variations of saliva are greater than those of blood.

L. W. RIGGS

Adrenaline content of the suprarenal capsules in total inanition. G. MOURIQUAND AND A. LEULIER. *Compt. rend. soc. biol.* **99**, 280-1(1928).—Guinea pigs receiving only water showed a reduction in their adrenaline output.

L. W. RIGGS

Wave-like variation of the contraction height of the skeletal muscle on introducing short periods of rest in its contraction series. KIYOSHI IWAKI. *Tohoku J. Exptl. Med.* **10**, 591-622(1928).—Expts. with frog gastrocnemius muscle exposed to air or immersed in Ringer soln. showed 22° to 26° as the most favorable temp. for the appearance of the wave-like oscillation. Conditions which act to hasten fatigue also act to hasten both onset and cessation of the waves of the summit line and vice versa.

L. W. R.

Some observations on pigment metabolism in the newborn. M. HINES ROBERTS. *J. Med. Assoc. Georgia* **17**, 143-8(1928).—The spinal fluid and blood serum of newborn negro infants were studied for pigment content. The van den Bergh test gave a positive "indirect" reaction in all serums and many of the deeper spinal fluids. The pigment content of the spinal fluid as measured by the icterus index varies directly with that of the blood serum and is approx. $1/140$ as great. The concn. of pigment in both serum and spinal fluid shows a gradual rise to the 4th day, then a gradual decline to normal by the 8th day. Clinical jaundice was not seen with icterus indices below 40. In intracranial hemorrhage the pigment concn. in the serum was only 30 times as great as in the spinal fluid.

H GIDEON WELLS

The lipid phosphorus-cholesterol ratio before and after feeding radiated eggs to tuberculosis patients. DUNCAN P. MCRAE AND THORSTEN INGVALDSEN. *Am. Rev. Tuberculosis* **17**, 520-1(1928).—No changes were found in the ratio of lipid phosphorus and cholesterol detd. in the patient's plasma by Bloor's method before and after feeding eggs radiated in thin layers for one-half hr. at a distance of 16 in. from a Hg quartz lamp. The findings were within the normal limits given by V. Meyer in a table of normal blood constituents. The clinical improvement noted could, therefore, not be attributed to a shift in circulating lipoids.

H. J. CORPER

Intense albuminuria exceeding greatly the protein content of the blood. W. STREPP AND F. PETERS. Univ. of Jena. *Deut. Arch. klin. Med.* **153**, 53-64(1926); *Chem. Zentr.* **1927**, I, 1034.—A case of congested kidneys with a fatal ending. The quantity of urine, which, with symptoms of severe heart insufficiency, at first increased by digitalis

suddenly diminished and acquired the consistency of a thick, almost clear, dark brown sirup of sp. gr. 1.112.2. The f.-p. depression of only 1.951° indicated a substance of high mol. wt. or colloidal. In a boiling test the whole mass coagulated. By pptn. with EtOH, coagulation by heat and addn. of $\text{Cl}_3\text{CCO}_2\text{H}$, 30.6, 26.4 and 28.7%, resp., of protein was obtained, the protein concn. thus exceeding that of the blood 3-4 fold. Salting out with Na_2SO_4 indicated 83.2% for the albumin fraction and 16.8% for globulin. The isoelec. point of the albumin fraction after 4 days' dialysis was at p_{H} 5.3 (by the Michaelis method). There was little inorg. material
C. C. DAVIS

The antigenic properties of lipoids. G. SOBERNHEIM. *Festschrift A. Tschirch* 1926, 431-4; *Chem. Zentr.* 1927, I, 2919-20.—Lipoids are capable of bringing about the formation of antibodies when small quantities of protein (hog serum) are added to lipid solns. obtained by extrn. with EtOH, C_6H_6 or other solvent. The antilipoid sera are completely non-sp., and act on the exts. of every substance contg. a lipid. The bacterial lipoids show a different behavior from the exts. of animal cells and organs.
C. C. DAVIS

Seasonal variation in the calcium content of infants' serum. H. BAKWIN and R. M. BAKWIN. *Am. J. Diseases Children* 34, 994-9(1927); *Expt. Sta. Record* 58, 493.—Detns. of the blood Ca of a large no. of sick and healthy babies from 3 to 24 months of age at monthly intervals from January, 1926, to March, 1927, inclusive, with the exception of July, August and September, showed a definite seasonal variation, the drop beginning during the late autumn, reaching the lowest point during the early spring months, and rising with the approach of summer. The values were consistently higher during the first three months of 1927 than of 1926, and the rise began earlier in 1927. Meteorological records showed more favorable weather conditions during February and March in 1927 than in 1926 in New York City, where the observations were made. The no. of infections during this period was also less.
H. G.

Study of the circulation in the normal and pathological kidney with Röntgenographic visualization of the arterial tree including the glomeruli. RALPH S. GRAHAM. *Am. J. Pathol.* 4, 17-31(1928); *Bull. Ayer Clinical Lab. Penn. Hosp.* 11, 58-73(1928).—Study was made of 48 human kidneys, removed at necropsy, injected with a radiopaque suspension contg. 17% BiOCl and 10% acacia in water, and subjected to Röntgenographic examn. Terminal values for urea N and creatinine were made on the blood taken at necropsy. The results failed to show a direct relationship between moderate arteriosclerosis and impaired renal function
JOSEPH S. HEPBURN

The bactericidal power of the blood of women during pregnancy and the puerperium. F. C. GELLER. *Arch. Gynakol.* 134, 141-4(1928).—The bactericidal power of the blood is markedly increased in the first 24 hrs. *post partum* and then slowly falls to normal. The bactericidal power of the blood, which is an unspecific resistance, was tested with hemolytic staphylococci according to Wright's method. It is probable that the increase in unspecific resistance after childbirth as well as at the close of menstruation is due at least in part to a resorption of cell or protein-split products from the wound surface of the puerperal or menstrual uterus
HARRIET F. HOLMES

Hypophysis and eclampsia. H. KÖSTNER. *Arch. Gynakol.* 133, 331-44(1928).—In eclampsia there is an increase in the activity of the hypophysis and an increased excretion of the hormone of the posterior lobe into the blood, which is toxic to the organism and brings about the symptoms typical of eclampsia, rise of blood pressure, kidney distribution, convulsions.
HARRIET F. HOLMES

The function of the liver in pregnancy. I. Storage of dyes in pregnancy. H. EUFINGER and C. W. BADER. *Arch. Gynakol.* 133, 720-32(1928).—In 100 cases of normal pregnancy and 33 cases of pathologic pregnancy 12-14 cc. of a 1% soln. of Congo red was injected intravenously and the concn. of the dye in the blood detd. 4 min. and 1 hr. after the injection. In normal pregnancy the storage capacity for Congo red is retarded, the retardation being particularly marked in the second half of pregnancy and *sub partu*. In the toxicoses of pregnancy retardation was especially great in cases of hyperemesis and icterus while in cases of nephropathy and eclampsia the results were not clear. The elimination of the dye depends not only on the condition of the reticulo-endothelial system but also on the chemico-physical structure of the blood. A delayed elimination of the blood was usually accompanied by an increase in colloid lability and a relatively low cholesterol content. The aldehyde reaction of Ehrlich is positive in both normal and pathologic pregnancies. A positive reaction is not specific for the presence of urobilinogen but indicates colloidal alteration of the blood in pregnancy. The almost regular presence of urobilin in the serum and urine during pregnancy, the increase of bilirubin in the blood and frequent occurrence of urobilinogen in the urine are an indication that in pregnancy the liver function deviates from the normal. H. F. H.

Effect of hyperthyroidism upon diabetes mellitus. FREDERICK A. COLLIER AND C. B. HUGGINS. *Ann. Surgery* **86**, 877-84(1927).—Great improvement of carbohydrate function follows thyroidectomy. The latter does not benefit carbohydrate tolerance in non-toxic thyroid states. Glucosuria in hyperthyroidism is an indication for the study of carbohydrate metabolism. FRANCES KRASNOW

Serodiagnosis of pregnancy with the Sdrodovskii modified Abderhalden test. M. LURIE, N. KOSAREV AND A. ROSENBLATT. *Bakteriol. Staatsinst., Baku. Z. Immunitäts.* **54**, 355-64(1928).—The Abderhalden test for pregnancy was made in the usual way except that the amt. of ninhydrin-reacting substances was quant. estd. The method was found to be sp. for the diagnosis of pregnancy. JULIAN H. LEWIS

The theory and method of the Wassermann reaction. MARGARETE STERN AND TONI FRANK. *Dermatologischen Universitätsklinik, Breslau Z. Immunitäts* **55**, 1-18(1928).—A study of a new method of complement titration for the Wassermann reaction. JULIAN H. LEWIS

Can guinea pigs produce a positive serum reaction and anaphylactic lipid antibodies from injections of homologous lipid and hog serum? LYDIA HENNING. *Univ. Hautklinik, Breslau Z. Immunitäts.* **55**, 19-33(1928).—Guinea pigs injected with alc exts. of guinea-pig kidney combined with hog serum were more sensitive to serum than were animals injected with serum alone. Thus the same results were obtained with homologous lipids as Klopstock obtained with foreign lipids. Occasionally the animals were sensitized with lipid alone. The guinea pigs injected with the lipid-serum mixt. did not give a positive reaction for syphilis (Wassermann, Sachs-Georgi, Meinicke). JULIAN H. LEWIS

The reproductive agent which changes the isoagglutination of red blood cells. V. FREIDENREICH. *Universitätsinst für allgem. Pathol., Kopenhagen. Z. Immunitäts* **55**, 84-101(1928).—The new and reproducing agglutinin that has been shown to develop in human blood on standing (*Z. Immunitäts* **52**, 87-107(1927)) is found to be nothing more than the effect of the growth of bacteria, 2 different organisms having been isolated that have this property. JULIAN H. LEWIS

Allergic reactions in hypersensitiveness to scabies. I. VON HÁNSZKY AND W. KREMER. *Pharmako-therapeut. Inst der Universität, Leiden. Z. Immunitäts* **55**, 102-6(1928).—Negative results in the passive transfer of local hypersensitiveness is no basis for placing asthma in a special class of allergic diseases, because, as is shown for asthma due to scabies and pediculosis, the passive transfer may be positive or negative depending on the stage of the disease. JULIAN H. LEWIS

The influence of the reticulo-endothelial system on the prophylactic effect of stovarsolan in spirochetal infections. P. I. RUBINSTEIN. *Mikrobiol. Forschungsinst des Volksunterrichtskommissariats R. S. F. S. R., Moskau. Z. Immunitäts* **55**, 107-17(1928).—The prophylactic effect and therapeutic action of arsenicals in spirochetal infections are entirely dependent on the functional efficiency of the reticulo-endothelial system. A dose of stovarsolan that is effective in 92% of normal animals is ineffective in 100% of animals after eliminating the reticulo-endothelial system either by blockade or splenectomy. If blockade is made during recurrent infection there is no sterilization in 42.5% and 12.7% die. "The action of the reticulo-endothelial system is to activate the chem. substances and is an independent function of the defense mechanism. JULIAN H. LEWIS

Chemospecific antigens. A. KLOPSTOCK AND G. E. SELTER. *Inst. für experimentelle Krebsforschung, Heidelberg. Z. Immunitäts* **55**, 118-41(1928).—The expts. of Landsteiner with chemically modified proteins were repeated and modified. By diazotization the original specificity is destroyed and antisera to this diazotized serum react with diazotized sera in general and independently of the source of the serum even if it be the immunized animal (rabbit). However, the antiserum reacts most strongly with the diazotized serum used for immunization. Serum combined with diazotized atoxyl and metanilic acid also produce sp. antisera which react little or not at all with the original serum. Bacterial protein combined with diazotized atoxyl forms a complex antigen. Rabbits immunized with it produce an antiserum that reacts in general with protein-atoxyl combinations although it also reacts with the native bacterial protein, showing that the atoxyl compd. retains its specie specificity. On the basis of the expts. made the ideas of Landsteiner on the nature of chemo-sp. antigens are questioned. An attempt is made to harmonize the facts with the results obtained with lipid-protein combinations. JULIAN H. LEWIS

Bacterial and antitoxin precipitins. E. HOEN, L. CHERTKOV AND V. ZIPP. *Staatlichen Bakteriolog. Inst., Odessa. Z. Immunitäts.* **55**, 149-50(1928).—Cultures of diph-

theria and cholera bacilli contain 2 different precipitinogens, the bacterial protein and the toxin.

JULIAN H. LEWIS

Further experiments on the action of serum on isolated vessel preparations. P. INTROZZI. *Forschungsinst. für Hyg. und Immunitätslehre, Berlin-Dahlem. Z. Immunitäts.* 55, 167-84(1928).—The action of normal serum from rabbits, cats, carp, guinea pigs, rats and eels on the blood vessels of rabbits, rats and guinea pigs was studied. The vaso-constricting substance was confined to the insol. albumin fraction of the sera. Ultra-violet light either weakened or destroyed the toxic action. There was no relation to temp. of the absorption of eel serum toxin by organ cells. The active substance in vaso-constricting sera was apparently not a complement-like thermolabile body. Serum taken at the height of digestion had the same activity as when taken during fasting. Serum from severe cases of human tuberculosis constricted, but not regularly, the blood vessels of tuberculous guinea pigs.

JULIAN H. LEWIS

Further experiments with anaphylaxis, especially passive anaphylaxis, studied with blood vessel preparations. E. FRIEDBERGER AND P. INTROZZI. *Forschungsinst. für Hyg. und Immunitätslehre, Berlin-Dahlem. Z. Immunitäts.* 55, 226-36(1928).—By means of the blood vessel perfusion method it is shown that an anaphylactogen loses its activity when heated 30 min to 100°. Radiation of a serum-eosin mixt with ultra-violet light destroys the sensitizing action of the serum without affecting its intoxicating properties. For guinea pigs sensitized with whole sheep serum the sol. albumin and euglobulin fractions are more active for intoxicating than the pseudoglobulin and insol albumin fractions. The perfusion method can be used for demonstrating passive as well as active anaphylaxis in guinea pigs and rats.

J. H. L.

Obtaining precipitating sera of high titer. W. GAEBTGENS. *Hyg. Staatsinst., Hamburg. Z. Immunitäts.* 55, 258-80(1928).—The intravenous injection of India ink in some instances increases the formation of precipitins. Sp. pptn. in an antigen-antiserum mixt. is increased and hastened in the presence of a lipid. Injections of lipoids can increase the production of precipitins but in about 1/2 of the sera unsp. antibodies render them useless for practical purposes. To find if this was due to the presence of 2 lipoids, that which was added and that already in the serum, a mixt. of heterologous lipid and serum extd. with ether was used for immunizing. However, the resulting antiserum was not any the less unsp. Immunization with mixts. of lipid and the sp. ppt. from antigen-antiserum mixts. produced an antiserum with increased species specificity. Dried serum free from lipid by extg. with alc. gave just as useful antisera as did native sera. The addition of homologous lipid to serum produced nonsp. antisera as often as when heterologous lipid was added.

JULIAN H. LEWIS

The concurrence of lipid antigens. A. KLOPSTOCK. *Inst. für exptl. Krebsforschung, Heidelberg. Z. Immunitäts.* 55, 304-11(1928).—Just as the body will not respond to a mixt. of 2 proteins as well as it will to them given separately, a phenomenon known as concurrence of antigens, so also will 2 lipoids show the same action. A concurrent action of Forssman heterogeneous antigen toward general organ lipoids could not only be demonstrated when the immunization was made with a mixt. of horse and rabbit kidney ext. and hog serum but when the horse kidney ext. and serum are injected at one place and the rabbit kidney ext. and hog serum at another place shortly afterward.

JULIAN H. LEWIS

The experimental basis of a preventive vaccination against cholera with toxoid. R. KRAUS AND N. NOVACS. *Staatl. Serotherapeut. Inst., Wien. Z. Immunitäts.* 55, 316-23(1928).—Expts. with guinea pigs indicate that the method should be tried with the human.

JULIAN H. LEWIS

Serological relation of tape-worm lipoids. H. SACHS AND A. KLOPSTOCK. *Inst. für experimentelle Krebsforschung, Heidelberg. Z. Immunitäts.* 55, 341-57(1928).—Rabbits injected with an aq. ext. of sheep tape-worms form lipid antibodies. Alc. exts. of the tape-worm have no antigen value when given alone but when mixed with hog serum are very active. The antiserum formed from the injection of the alc. ext. and hog serum reacts with the aq. ext. Complement fixation with antiserum and aq. ext. is inhibited at 0°, while with the alc. ext. the reaction is obtained at that temp. Antiserum to the alc. ext. and hog serum reacts with other organ exts. but not with lecithin, although an anti-lecithin serum shows that lecithin is present in the tape-worm alc. ext. The tape-worm substance contains not only sp. but undifferentiated lipoids whose activity is inhibited through the principle of concurrence of antigen.

JULIAN H. LEWIS

The influence of carcinomatous human serum on fermentation. G. LANDEGGER AND H. PIRKER. *Staatl. Serotherapeut. Inst., Wien. Z. Immunitäts.* 55, 358-63(1928).—In the serum of carcinoma patients, of pregnant women, and most healthy men there

is a substance that stimulates the fermentation of sugar by yeast. Normal leucocytes either inhibit this stimulating action or the fermenting properties of normal leucocytes is inhibited in the presence of carcinoma serum. The opinion is expressed that the stimulating action of serum on glucolysis is a condition for the development of carcinoma.

JULIAN H. LEWIS

Anaphylaxis with isolated blood vessel preparations using egg white as antigen. P. INTROZZI. *Forschungsinst. für Hyg. und Immunitätslehre, Berlin-Dahlem. Z. Immunitäts.* 55, 439-42(1928).—It has been claimed that the constriction of sensitized blood vessels perfused with sera is not anaphylactic in origin but is due to the primary toxicity of the sera and that no constriction is obtained in such preparations sensitized with egg white because egg white is not toxic to normal tissues (cf. Goldberger, *J. Exptl. Biol. Med.* (Russian) 1926, No. 4, 12). I find also that egg white causes no constriction of blood vessels in normal tissues but in tissues from sensitized animals a reaction appears as early as 48 hrs. after sensitization.

JULIAN H. LEWIS

The serological relation of the protein of a tissue fragment grown in a medium composed of plasma of another species. R. KIMURA. *Kaiser-Wilhelm-Inst. für Biol., Berlin-Dahlem. Z. Immunitäts.* 55, 443-4(1928).—Evidence is given, using immunological methods, that a tissue fragment grown a long time (18-55 days) in plasma of another species loses its species specificity and assumes that of the medium, although it is admitted that complete evidence fails because the large no. of controls required is not possible with the small amt. of material which tissue cultures afford.

J. H. L.

Chemospecific antigenic function in simple mixtures. II. A. KLOPSTOCK AND G. E. SELTER. *Inst. für experimentelle Krebsforschung, Heidelberg. Z. Immunitäts.* 55, 451-71(1928).—Simple mixts. of diazotized atoxyl and serum possess the chemospecific properties of the combination of diazotized atoxyl and serum as made by the complicated process of Landsteiner. A soln. of diazotized atoxyl undergoes changes on standing which renders it unable to combine with serum, but this changed soln. is yet able to bind antibodies for the combined serum-diazotized atoxyl. The change in chemospecificity of serum mixed with diazotized atoxyl does not take place immediately and the rate of change varies with unknown factors. Serum previously treated with alkalis, acids and alc. undergoes changes in the diazotized atoxyl mixts. better than native serum. The strongly sp. character of the change produced in these simple mixts. of serum and diazotized atoxyl was shown by comparison with similar mixts. made with diazotized Na metanilate. The loss of species specificity in atoxyl serum combinations as prepared by Landsteiner is attributed to the severe treatment of the serum of producing the compd. In simple mixts. species specificity is not lost. Such mixts. act as chemospecific antigens *in vivo* in rabbits as well as *in vitro*, but the serum used in the mixt. must be a foreign serum although the resulting rabbit antiserum will react with a rabbit-diazotized atoxyl mixt. Such an antiserum usually contains only chemospecific antibodies, but sometimes antibodies specific for the foreign serum are also present, and occasionally only the latter are found. This variable relation is attributed to concurrence of antigen. When the 2 types of antibodies are present they can be sep'd by selective absorption.

J. H. L.

The action of rabbit immune serum on cells *in vitro*. R. KIMURA. *Kaiser-Wilhelm-Inst. für Biol., Berlin-Dahlem. Z. Immunitäts.* 55, 501-11(1928). The serum of a rabbit injected repeatedly with a suspension of chicken embryos inhibits the growth of different embryonal cells *in vitro*, this action being on chicken as well as duck embryonal cells. The serum is injurious for cells already grown *in vitro*. Complement is not necessary for this toxic action. Heat and long standing weaken its activity. There is some species specificity of the cytotoxic serum in that it does not act on mouse or rabbit cells. The injection of embryo juice, chicken plasma, duck plasma or chicken leucocytes into rabbits does not produce an antiserum with the same cytotoxic action although it may have the same or higher precipitin titer as compared with the antiserum to embryo cells. Injections of embryo brains into rabbits produce an antiserum which is sp. for brain tissue of chicken or duck embryo cells. By injecting a cytotoxic serum into a rabbit an anti-cytotoxic serum can be produced.

JULIAN H. LEWIS

Viscosity of the blood in histamine shock. RUSSELL A. WARD. *Univ. of Chicago and Univ. of Western Ontario. Am. J. Physiol.* 84, 563-5(1928); cf. *C. A.* 21, 1301, 2502.—The fall in blood pressure in histamine shock was accompanied by a reduction in the viscosity of the blood.

J. F. LYMAN

Treatment of parathyroidectomized dogs with cod-liver oil. JOHN C. BROUGHNER. *Univ. of Oregon. Am. J. Physiol.* 84, 583-6(1928).—Feeding cod-liver oil to dogs whose parathyroids had been removed was very beneficial. It delayed the fall of blood Ca to the tetanic level, lessened the severity of tetany when it did occur and

finally resulted in a return of blood Ca to the normal level after 30 to 40 days' treatment.

J. F. LYMAN

The glucemia titer and its variations in eclampsia. O. M. BERNARDI. *Boll. soc. ital. biol. sper.* 3, 317-9(1928).—The av. blood sugar of 9 normal non-pregnant women was 0.080%; that of 5 normal pregnant women was 0.96%. The blood sugar of 4 pregnant women with eclampsia was also detd. from time to time. There was not a const. hyperglucemia. If the increased density of the blood is taken into account, B. found a lowering of blood sugar in some cases.

PETER MASUCCI

The elimination of oxalic acid in phlorhizin diabetes. P. DE LUCIA AND M. NAPOLI. *Boll. soc. ital. biol. sper.* 3, 324-6(1928).—The expts. were made on a young dog kept on a const. diet (350 g. bread per day). The urine was collected for a few days and oxalic acid detd. by the Salkowski method. After the av. daily elimination was established, diabetes was induced by means of phlorhizin, 10 cg. subcutaneously administered in oily suspension. The urine was tested for oxalic acid and glucose until the latter disappeared. The conclusions are that in phlorhizin diabetes there is an increase in oxalic acid elimination.

PETER MASUCCI

The influence of sensitization with lens protein on the formation of traumatic cataract in dogs. WILLY BENDER. Univ. of Leipzig. *Centr. Bakt. Parasitenk. I Abt.* 106, 7, 10(1928).—Injection of the lens of the eye with NaCl by the method of Solenkowsky (cf. Solenkowsky, *Klin. Monatsbl. Augenheilk.* 75) produced cataract in dogs, the extent of which varied directly with the concn. of the NaCl soln. Dogs which had previously received intraperitoneal or subcutaneous injections of exlens protein responded much more markedly.

JOHN T. MYERS

Specific cell stimulation. G. BESSAU AND C. DETERING. Univ. Leipzig. *Centr. Bakt. Parasitenk. I Abt.* 106, 11, 20(1928).—By sensitizing animals with small doses of serum (0.1 cc. intracutaneously) cell changes occur as manifested by local anaphylaxis without any type of free humeral antibodies. With larger doses cell sensitization can be demonstrated plus the slow formation of humeral antibodies. Apparently the primary action of an antigen is cell stimulation, the production of free antibodies coming later.

JOHN T. MYERS

Dyes as hemagglutinins. MARTIN GUTMANN. Univ. Breslau. *Centr. Bakt. Parasitenk. I Abt.* 106, 68, 73(1928). Washed human erythrocytes were agglutinated by all the basic dyes tried except fuchsin. Acid dyes had no effect. There was parallel serum flocculation. This may be due to the neutralization of the neg. charge on the erythrocytes by the acid dye. Expts. with acids and alkalies were unsatisfactory because they quickly destroyed the erythrocytes. Alc. inhibited dye agglutination. Aq. erythrocyte exts. gave no ppt. with the dyes. There are individual differences in cell agglutinability but no relation to Jansky blood groups.

JOHN T. MYERS

The Pfeiffer endotoxin concept and pathology. P. HUEBSCHMANN. *Centr. Bakt. Parasitenk. I Abt.* 106, 87, 99(1928).—The concept is very useful in explaining the mechanism of constitutional manifestations in many infections.

JOHN T. MYERS

The nature of "percutaneous immunization" against staphylococcus infections in rabbits. WERNER KOLLATH AND HEINRICH HERFARTH. Univ. Breslau. *Centr. Bakt. Parasitenk. I Abt.* 106, 120, 33(1928). A strain of staphylococcus was used which produced a phlegmon in rabbits. Its virulence was raised to a max. by 6 passages through the vitreous humor of the eyes of rabbits. The local application of Besredka filtrates, ordinary bouillon, peptone water, meat infusion, tryptophan, l-leucine, l-cystine, l-tyrosine and l-alanine had a protective effect against intracutaneous injections. Dry and moist heat was without influence. It is possible that the inhibiting effect of peptone is due to the local formation of histimine or histidine. Casein, uric acid and allantoin had no effect. The local resistance is non-specific and not due to true immune reactions.

JOHN T. MYERS

Bactericidal and growth inhibiting action of blood on tubercle bacilli. GERTRUD MEISSNER. Univ. Breslau. *Centr. Bakt. Parasitenk. I Abt.* 106, 210-36(1928).—The blood of tuberculous guinea pigs and rabbits contains a more strongly inhibiting substance against the tubercle bacillus than does that of normal animals, while that of scorbutic animals contains less than the av.

JOHN T. MYERS

The relationship between the amount of thermostable and thermolabile agglutinin in the blood of typhoid patients and the clinical course of typhoid fever. LEO OLITZKI. Hadassah Med. Organization, Safed, Palestine. *Centr. Bakt. Parasitenk. I Abt.* 106, 247-59(1928).—The typhoid bacillus has two agglutinins, a thermolabile (H) antigen from the ectoplasm, and a thermostable (O) antigen coming from the endoplasm. There is no relationship between the clinical course and the H agglutinin curve. In severe cases of typhoid the O agglutinins are absent or the titer is very low. In mild cases there

is usually a large amt. of O from the beginning; if absent the case is apt to become severe later.

JOHN T. MYERS

The influence of complement on agglutination, precipitation and bacteriophage action. LEO OLITZKI. Univ. Breslau. *Centr. Bakt. Parasitenk. I Abt.* **106**, 259-67 (1928).—Complement enhances the action of O (thermostable) agglutinins. Inactivation favors bacteriophage action.

JOHN T. MYERS

The formalin resistance of agglutinins. LEO OLITZKI. Hadassah Medical Organization, Safed, Palestine. *Centr. Bakt. Parasitenk. I Abt.* **106**, 267-78 (1928).—The group of HCHO-resistant agglutinins contains all of the H (thermolabile) agglutinins of the typhoid, paratyphoid and proteus groups of bacteria, and the normal H agglutinins of ox serum. The HCHO-non-resistant group of agglutinins contains the O (thermostable) agglutinins of the above bacteria, all normal O agglutinins, those of all non-motile bacteria, and the X19 proteus agglutinin, of typhus patients (Weil-Felix reaction). The X19 agglutinins are very labile, being destroyed after a few days exposure to HCHO. This will distinguish between X19 and specific proteus agglutinins. Formalin destroys the agglutinophore and leaves the haptophore group unchanged.

J. T. M.

The properties and action of anthrax immune serum. ALFRED PATTERSON. Carolinian Inst. Stockholm. *Centr. Bakt. Parasitenk. I Abt.* **106**, 295-300 (1928). Anthrax immune serum contains agglutinins, precipitins and complement binding bodies; but not lysins or opsonins. The exudate about the lesions of infected animals contains a neg. chemotactic substance for anthrax bacilli. Immune serum contains substances which enhance the action of this substance, which are the only immune substances of protective value.

JOHN T. MYERS

The further development of the knowledge of endotoxins. WOLFGANG WEICHARDT. *Centr. Bakt. Parasitenk. I Abt.* **106**, 342-8 (1928).—Buere neg. exts. of typhoid bacilli were prepd. by the method of Abderhalden (Cf. Abderhalden, *Handbuch der biol. Arbeitsmethoden*. Abt. XIII Teil II). When hemolytic streptococci were grown in Tyrode soln., with Na asparaginate as a source of N and glycerol as a source of C, the addn. of 0.1% of such ext. stimulated growth definitely. Under similar conditions the growth of diphtheria bacilli was markedly increased. The contraction of perfused fatigued heart muscle was definitely stimulated. Further similar work may throw light on the mechanism of infectious processes.

JOHN T. MYERS

Low-temperature hemagglutinins (frigid agglutinins). I. YU. Medical High-school, Keijo, Seoul. *Centr. Bakt. Parasitenk. I Abt.* **106**, 388-96 (1928).—The hemagglutinins which react only at 0° are different substances from those which react at body temp.

JOHN T. MYERS

The acid agglutination of influenza, pertussis and Koch-Weeks bacilli. BERNARD FISCHER. Univ. Breslau. *Centr. Bakt. Parasitenk. I Abt.* **106**, 417-25 (1928).—All of these organisms are acid agglutinable, the optimum being between pH 3.5 and 5.5. There is a marked variation among various strains. Virulence is directly proportional to agglutinability. Acid agglutination will not distinguish between different species, Bact. Cohen and Bact. canis being as readily agglutinable as true Pfeiffer bacilli. Acid-agglutinated organisms washed with isotonic NaCl soln. are still agglutinable by immune serum.

JOHN T. MYERS

A new tuberculosis antigen. R. ZDRAŽIL. Agr. School, Olmutz. *Centr. Bakt. Parasitenk. I Abt.* **107**, 95 (1928). One kg. of ground tuberculous human lung is mixed with 1 l. of water and allowed to stand 3 days, being brought to boil several times. The filtrate is evapd. to dryness on a water bath. Each 30 g. of dry residue is extd. with acetone for 6 to 7 days, filtered, the residue dried at 37°, extd. with 50 cc. of MeOH for 10 to 12 days, filtered, and the filtrate stored in rubber-stoppered flasks in 5 to 10 cc. ams. It gives a ppt. with ether serum or plasma. Lues occasionally reacts but not arteriosclerosis.

JOHN T. MYERS

Studies on the mechanism of Trichinella infestation. II. The influence of glycogen on muscle invasion. JULIAN H. LEWIS. Univ. Bâle. *Centr. Bakt. Parasitenk. I Abt.* **107**, 114-26 (1928).—In *Trichinella* invasions in guinea pigs, the masseter muscles and the diaphragm are attacked by preference. These have much less glycogen than those which are nearly exempt, i. e., the muscles of the extremities. Repeated *Trichinella* feeding at short intervals (2-5 days) leads to a continued migration into the same muscles until an overwhelming no. of fibers contain parasites. A marked previously existing infestation in a given muscle, with its accompanying disturbance of metabolism and function, and loss of glycogen, will not protect the intact fibers from further invasion from the blood stream. Large ams. of glucose by mouth hinder the passage of the parasites from the blood to muscle. Insulin has the opposite effect.

JOHN T. MYERS

Lipoid antibodies. II. Lipoid antibody formation after parenteral injection of

milk and milk products. FELIX KLOPSTOCK. Kaiser Wilhelm Inst. Biochem., Berlin-Dahlem. *Centr. Bakt. Parasitenk.*, I Abt. 107, 127-32(1928); cf. C. A. 22, 1390.—Casein called forth no lipid antibodies. Lactalbumin and alc. milk ext. gave a slight response. Whole milk gave a very active, and butter an extremely active, response. None of these substances was biologically pure. Calf tallow, lard and olive oil were somewhat antigenic. **III. Lipoid antibodies following parenteral injections of amino acids and polypeptides.** *Ibid* 129-32.—Injections of glycine, alanine and leucine produced lipid antibodies, but tyrosine did not. The dipeptides, glycylserine and leucylglycine, the tripeptide, diglycylglycine and the tetrapeptide, alanyldiglycylglycine called forth lipid antibodies. These substances probably unit with body cell or fluid constituents, causing changes which give the serum an affinity for lipoids. This may give rise to colloidal changes which make possible a colloidal reaction with lipoids as antigen.

JOHN T. MYERS

The relationship of "floccular" and "granular" types of agglutination to each other and to specificity. K. AOKI. Univ. of Sendai. *Centr. Bakt. Parasitenk.* I Abt. 107, 428-31 (1928).—In many instances the sp. agglutinins produce large floccules and the non-sp. ones, small granules, but the opposite occasionally holds. With *B. cholerae suis*, both sp. and non-sp. agglutinins produce floccules. After flagellated bacteria are heated, they produce floccular instead of granular agglutinins. The specificity of agglutinins must depend on the physico-chem. constitution of the homologous organism, and is not related to the flagella or to the ectoplasmic layers.

JOHN T. MYERS

Serological studies of schistosomiasis japonica. S. MIYAJI AND B. IMAI. Med. School, Niigata, Japan. *Centr. Bakt. Parasitenk.* II Abt. 73, 237-46(1928).—With emulsions of adult worms, complement-binding and precipitating substances can be detected in the blood of exptl. animals. The emulsions are not heterogenetic antigens. An isotonic NaCl ext. is much more strongly antigenic than an alc. ext. The latter often gives a pos. reaction with a syphilitic serum, while the former does not. In endemic regions the antibodies are often present in apparently normal individuals.

J. T. M.

Contribution to the study of isohemoagglutinins from the medico-legal standpoint. KAN-ITIVOSIDA. *Ann. méd. légale (criminol. police sci.* 8, 249-54(1928).—A study of the phenomena of isohemoagglutination led to the following conclusions. (1) most serous liquids, and also those secreted by the human body, have specific isohemoagglutinins of the same type as those of the blood serum; (2) all the cells of the human body possess the power of attracting and hold specific isohemoagglutinins of the same type as the blood serum; (3) all serous and secreted liquids and all exts. of internal human organs contain a substance which represses the agglutinating power of isohemoagglutinins towards agglutinogens.

A. PAPINEAU-COUTURE

Hemotoxin of the venom of *Synanceja horrida*. J. V. DUHIG AND GWEN JONES. *Australian J. Exptl. Biol. Med. Sci.* 5, 173-9(1928).—The venom of *Synanceja horrida* (stone fish) by itself produces lysis of guinea pig, sheep and human red cells, without the assistance of lecithin or alexin. Fresh unheated serum, when added to cells of the same species, inhibits hemolysis of guinea pig, sheep and human red cells by this venom. In the case of guinea-pig serum, a very high diln. is sufficient to protect against a min. hemolytic dose. Human serum, besides protecting against lysis of cells of its own species, also protects sheep cells. Guinea-pig serum heated to 55° for 20 min. inhibits hemolysis, but the same serum heated to 60° for 30 min. does not completely inhibit hemolysis. Lecithin can reactivate venom, the cytolytic power of which has been inhibited by fresh serum.

L. W. RIGGS

Non-colloidal substances with cryptotoxic properties. H. VINCENT. *Compt. rend.* 186, 1175-7(1928); cf. C. A. 19, 2701; 20, 3187.—Antipyrine, pyramidone and Na salts of acids of the benzenic or hydroxybenzenic series when forming colloidal solns. have the power of neutralizing tetanus toxin when added to a prepn. of the latter. Na salicylate has a remarkable power of neutralizing tetanus toxin as shown by tests with guinea pigs. Rabbits show pronounced resistance to repeated inoculations of the complex toxin-salicylate. Non-colloidal substances such as Na salts of benzoic, hippuric, butyric, pyruvic and mucic acids have a slight neutralizing power on tetanus toxin as compared with colloidal Na salicylate. These findings furnish a partial explanation of the beneficial action of Na salicylate in the treatment of toxo-infectious maladies.

L. W. RIGGS

Application of the acetone method to the study of the distribution of the antibodies in agglutinating serums in the course of immunization. MAURICE PIETRE and ANDRÉ CHRÉTIEN. *Compt. rend.* 186, 1240-2(1928); cf. C. A. 22, 810, 1393, 1610.—The agglutinating power appears to be attached to the serum globulin during the first phases of agglutination and in the later phases to the serum albumin. An

increase in the total ext. obtained by acetone and especially of the serum albumin corresponds to an increase in the agglutinating power L. W. RIGGS

Ultrafiltration of diphtheria toxins. F. PRZESMYCKI, L. LIPOWSKI AND ST. SIERAKOWSKI. *Compt. rend. soc. biol.* **98**, 1231-2(1928).—By the method of Beckhold-König, the ultrafiltration of diphtheria toxins proved that certain filters allowed all of the toxin to pass, others allowed none. Advantage of these facts was taken to purify and concentrate diphtheria toxins to some extent L. W. RIGGS

Natural antibodies and placental permeability. L. NATTAN-LARRIER, G. RAMON AND P. LÉPINE. *Compt. rend. soc. biol.* **98**, 1279-81(1928).—Pseudo-globulin is the principal if not the only carrier of the anti-trypanosomic substance of the human serum, while euglobulin is the carrier of antishoop hemolysins of human blood. Both the anti-trypanosomic and hemolytic substances are incapable of traversing the placenta. On the other hand the placenta is permeable to artificial antibodies, diphtheria toxin and tetanus toxin. L. W. RIGGS

Content of glutathione in the testicles of thyroidectomized guinea pigs. ANSELMO CRUZ. *Compt. rend. soc. biol.* **98**, 1588-90(1928).—The glutathione content in the testicles of 17 normal animals ranged from 134 to 194 mg. per 100 g. of tissue. In 13 thyroidectomized animals the range was from 115 to 199 mg., and the time between thyroidectomy and the detn. of glutathione ranged from 1 to 35 days. L. W. RIGGS

Alkaline reserve in the blood of the tuberculous guinea pig. LOPO DE CARVALHO AND FERREIRA DE MIRA FILS. *Compt. rend. soc. biol.* **98**, 1596-8(1928).—During the early stages of the disease the alk. reserve does not differ from normal. In the last phases and as death approaches there is a fall in the alk. reserve. **Alkaline reserve of the blood in pulmonary tuberculous patients.** *Ibid.* 1598-600. In patients with tuberculosis the alk. reserve of the blood tends to diminish and this diminution becomes more pronounced with the advance of the disease. This is explained by the changed metabolism of proteins and incomplete oxidation of org. acids produced in the course of disassimilation. This results in an excess of ammoniacal N and the presence of ketonic substances in the urine, indicating a state of acidosis. The alk. reserve varies with the amelioration or aggravation of the disease. L. W. RIGGS

Reducing power of the tissues of the tuberculous guinea pig. FERREIRA DE MIRA FILS. *Compt. rend. soc. biol.* **98**, 1611-2(1928).—The reducing power of the tissues during the period characterized by infiltration in the node of inoculation remains about normal. When the animal was in the state of general infection the reducing power fell from 10 to 23% in the 18 animals tested. L. W. RIGGS

Urobilinemia in the dog after hepatectomy. E. CORNEJO SARAVIA AND M. ROYER. *Compt. rend. soc. biol.* **99**, 171-2(1928).—The contradictory results of expts. with 4 dog are discussed. L. W. RIGGS

Muscular lactic acid in rats derived of suprarenals. P. MAZZOCCO. *Compt. rend. soc. biol.* **99**, 174-6(1928), cf. *C. A.* **22**, 630. The av. muscular lactic acid after tetanization for 1 min. was greater in rats deprived of suprarenals than in controls, but the differences were less than those obtained in a previous study. L. W. RIGGS

Chemical tests of the blood. Indications and interpretation. REED ROCKWOOD. *J. Am. Med. Assoc.* **91**, 157-66(1928).—To avoid unnecessary chem. detns. with expense to the patient or hospital, the following suggestions to the physician are made: (1) Never ask for both non-protein N and urea tests in the same patient. (2) Except in emergency, never ask for a non-protein N detn. when the excretion of phenolsulfonephthalein is normal. Det. the output of phenolsulfonephthalein first. (3) Never ask for the creatinine value of the blood unless the non-protein N content is above 60 mg. per 100 cc. Then det. the creatinine as a matter of routine. (4) Det. uric acid only in cases of gout or suspected gout. (5) Det. blood sugar in cases only of diabetes, suspected diabetes or hypoglycemia. (6) Test the CO₂-combining power of the plasma in (a) diabetic patients with diacetic acid in the urine; (b) uremic patients with N retention and dyspnea; (c) patients showing toxic symptoms who are receiving large doses of alkali; (d) patients with conditions assocd. with disturbed motility of the gastrointestinal tract with marked toxemia; (e) all types of tetany. (7) Chloride, non-protein N and CO₂-combining power detns. should be made in all cases of disturbance of gastrointestinal motility with marked toxemia. (8) Ask for serum bilirubin or icterus index tests in cases of jaundice, but do not pay too much attention to borderline values. (9) Ask for blood Ca detns. in cases only of tetany of unknown origin. (10) Inorg. P tests, if practicable, are necessary in cases only of rickets and infantile tetany. L. W. RIGGS

Microchemistry of nuclear inclusions in virus diseases. F. V. COWDRY. *Science* **68**, 40-1(1928).—This paper reports the reactions of nuclear inclusions to the Bensley-

Macallum test for masked Fe, also the Feulgen reaction and a few of the solys. of these inclusions. The test for Fe was neg. with inclusions of chicken-pox, herpes, Virus III disease of rabbits and the salivary gland disease of guinea pigs. The Feulgen reaction (cf. C. A. 21, 2138) was described and its application to the inclusions above named gave negative results except with the inclusions of the submaxillary glands of the adult guinea pig toward which the reaction was doubtful. The evidence indicates that positive results with the Feulgen reaction are given only by substances contg. thymonucleic acid. It appears that the reaction is sp. and elective for a distinctive nuclear component of some kind.

L. W. RIGGS

Precipitins produced by treatment with aqueous extract of fowl sarcoma. HARUJIRO YOSHIKAWA. *Sei-ikwa Med. J.* 47, No. 3, 3-4 (1928).—Antiserum was obtained by means of repeated intravenous injections with the aq. ext. of minced fowl sarcoma tissue in a rabbit. The mixt. of antisera thus obtained and an aq. ext. of fowl sarcoma gives a marked precipitin reaction. Normal serum gave no precipitin reaction with the aq. ext. of fowl sarcoma. The mixt. of antisera and the ext. of skeletal muscles of an untreated normal fowl produces no ppt. Accordingly blood serum of rabbits immunized with aq. ext. of fowl sarcoma gives sp. ppts when mixed with aq. ext. of fowl sarcoma.

L. W. RIGGS

Gastric lipase in various stomach diseases. KUNIO ANDO. *Nagaya J. Med. Sci.* 2, 103-6 (1927).—The influence of the acidity on the gastric lipase content of the gastric juice was studied. The gastric juice was collected in the morning 1 hr. after a test meal of 80 g. white bread and 200 cc. water. The p_H was estd. according to Michaelis' indicator method, while the activity of the lipase was detd. by Ogawa's modification of the tributyrin method of Michaelis and Rona. One-cc. phosphate buffer of p_H 5.7, which is the optimal acidity for the gastric lipase, was mixed with 8-cc. tributyrin soln. and 1-cc. gastric juice diluted with 19-cc. water, and the decomposition of the tributyrin observed. The lipase was not decreased in hyperacidity (p_H 1.1-1.5) and gastric ulcer (p_H 1.2), while in anacidity, gastric cancer and other diseases with a p_H above normal, it was considerably lowered.

G. SCHWOCH

The plasma proteins in leprosy. M. H. NEILL AND MARGARET M. DEWAR. *U. S. Pub. Health Service Pub. Health Bull.* 168, 1-20 (1927).—A quant. study on the plasma proteins of patients suffering from leprosy as compared with those of healthy persons. The plasma proteins were detd. by Wu's method. The controls showed an av. of 0.33% fibrin, 5.23% albumin, 2.29% globulin, the value of the total proteins thus being 7.52%, and the ratio albumin:globulin being 2.4. The total proteins stayed about the same in the leprosy cases, while fibrin was increased and the albumin:globulin ratio was lowered. In the cases with few or no leprosy bacilli and with patients in poor condition, the av. values were: fibrin 0.40; albumin 4.15; globulin 3.35; total proteins 7.50; albumin:globulin ratio 1.2. In cases with numerous leprosy bacilli and with patients in poor condition, fibrin was 0.44; albumin 3.94; globulin 3.55; total proteins 7.49; albumin:globulin ratio 1.1. Improved cases showed the values of fibrin and globulin returning to normal. In acute leprosy fever, a fibrin value of 0.60 and an albumin:globulin ratio of 0.9 was found. In some cases of advanced active pulmonary tuberculosis compared with others in an improved state of the same disease, fibrin values of 0.49 and 0.31, resp., and albumin:globulin ratios of 0.9 and 1.0, resp., were found. The total proteins were low in both stages (6.73 and 6.57, resp.); also in patients with acute broncho-pneumonia, the total proteins were low (6.00), fibrin was high (0.56) and the albumin:globulin ratio low (0.8). Numerous references are given.

G. SCHWOCH

The amount of lipase in the blood serum of lepers. M. H. NEILL AND MARGARET M. DEWAR. *U. S. Pub. Health Service Pub. Health Bull.* 168, 21-7 (1927).—The investigations were carried out to check Rogers' statement that untreated cases of leprosy showed a greatly reduced lipase content of the blood serum (*Lancet* I, 1207 (1924); C. A. 17, 3707). The technique employed was very similar to the one described by Rogers, the liberation of butyric acid from ethyl butyrate serving as indicator of the quantity of lipase present in the blood serum. The butyric acid was titrated with 0.02 N NaOH. It was found that, in general, the leprosy cases, whether improving or not improving, showed a normal content of blood lipase. Chaulmoogra ester injections did not increase the blood lipase. Low amts. were found only in some acute exacerbations of leprosy, besides this, in some cases of advanced pulmonary tuberculosis and liver diseases.

G. SCHWOCH

The effect of venous stasis on the proteins of blood plasma and on the rate of sedimentation of the red blood corpuscles. E. D. PLASS AND M. D. ROURKE. *J. Lab. Clin. Med.* 12, 735-41 (1927).—Prolonged venous stasis leads to blood dehydration and to an increase of plasma proteins. The fibrin, globulin and albumin are each increased

and to a greater extent than can possibly be accounted for by concn. of the plasma alone. The increase in the separate proteins is not equal to each other, nor is any one consistently higher or lower than the others. These authors believe that certain catabolic products formed in the tissues by the anoxemia imposed by the venous stasis act upon the cell membranes of both capillaries and tissue cells, increasing their permeability to protein. It is suggested that the lymph fluid has increased in protein content by diffusion of protein from the cytoplasm of the tissues which it surrounds, and that this lymph fluid, having become higher in protein than normal plasma, subsequently loses protein to the plasma, thereby increasing the total plasma proteins. The marked increase in fibrin during venous stasis points to reserve fibrin in the tissues. The sedimentation rate is increased by prolonged venous stasis and it is suggested that the increase is probably due chiefly to increased fibrin. Care should, therefore, be exercised in the use of the tourniquet or other constriction during the taking of blood upon which the sedimentation rate or plasma proteins are to be detd. E. W. W.

Methods for making a stable emulsified syphilitic antigen. FREDERICK PROESSCHER, ALBERT ARKUSH AND ALBERT KRUEGER. *J. Lab. Clin. Med.* 12, 908-11(1927).—Prepn. of "chloroform antigen I" and "chloroform antigen II" is described. These antigens were neither anticomplementary nor hemolytic in doses of 1 cc. of the undiluted antigen, and possess great stability of their antigenic properties. No expts. were encountered which would not keep for at least one year. ETHEL W. WICKWIRE

The origin and nature of the Wassermann antigen. L. G. HADJIOPOULOS AND REGINALD BURBANK. *J. Lab. Clin. Med.* 12, 973-8(1927).—Antigens cannot be considered as homogeneous material, but are composed of: (a) the "immunogenic," i. e., immunity-exciting or antibody-producing fraction, a property residing in the protein mol., and (b) the "immunophilic," i. e., the antibody-fixing property residing in the lipin mol. This theory applied to the heart muscle tissue proved correct by artificially inducing the Wassermann reagin in exptl. animals by the parenteral introduction of the immunogenic fraction and the subsequent fixation of the latter by the immunophilic lipin fraction. **The duality of the antigenic nature of erythrocytes.** *Ibid.* 979-82.—The same principle was applied in the case of sheep's erythrocytes and found strictly correct, thus demonstrating the dual nature of similar antigens. E. W. W.

"Acetone body" formation and the chemical affinity of oxygen for carbohydrate and fatty acid. DWIGHT M. ERVIN. *J. Lab. Clin. Med.* 12, 1059-65(1927).—The explanation offered for the chemistry of the "acetone bodies" is independent of the theory of the oxidation of glucose (lactic acid) and is applicable to all pathol. states where the quantity of fatty acid to be oxidized rises above a given ratio of 0 per mol. of fatty acid. ETHEL W. WICKWIRE

The relative diagnostic value of the Levinson test and the glucose content in cerebrospinal fluid. ALFRED S. GIORDANO AND MARJORIE ABILSON. *J. Lab. Clin. Med.* 13, 489-95(1928).—Low glucose values are not diagnostic of tuberculous meningitis, even in the absence of pyogenic organisms, and the percentage of false reactions in the Levinson test is too high to be of positive diagnostic aid. The glucose content of the cerebrospinal fluid yields valuable diagnostic information when correlated with all possible available clinical data. The chloride content in tuberculous meningitis is less than 700 mg. and not const. in other conditions. ETHEL W. WICKWIRE

A method of differentiating different types of cooked meat by the precipitin reaction (ROSENBERG) 12.

H—PHARMACOLOGY

A. N. RICHARDS

A home-made preparation of iodized oil for opaque injections of tuberculous sinuses. CLARKE BLANCE AND HARVEY R. LIVESAY. *Am. Rev. Tuberculosis* 17, 481-8(1928).—The details are given for the prepn. of iodized oil from mazola oil (corn oil). This new prepn. of iodine will penetrate into very small sinuses where Ia or Bi will not go if thick enough to cast a shadow in the x-ray. The prepn. also drains out of sinuses readily, and does not cause burrowing in other directions. It is non irritating and cheap to prepare. H. J. CORPER

Studies of the action of antipyrine. I. Viscometric investigations of the action of antipyrine in promoting the coagulation of the protein substances of blood serum. PIERO TESTONI. Univ. Sassari. *Arch. fisiol.* 24, 192-200; *Chem. Zentr.* 1927, I, 1184.—The degree to which the viscosity is increased by antipyrine depends upon its concn. and the concn. of the protein in the serum. The action of antipyrine in pro-

moting coagulation depends upon its pH group, and its local hemostatic action is related to this coagulation of the protein. C. C. DAVIS

An experimental study of narcosis, which is at the same time a contribution to the pathological physiology of narcosis. I. Narcosis from the standpoint of acid-base equilibrium. II. Acid-base economy and factors which are operative during narcosis. IMMO WYMER. *Deut. Z. Chr.* 195, 353-98, 399-425; *Chem. Zentr.* 1927, 1, 1183.—In ether narcosis, the alkali reserve diminishes, but later excess compensation occurs. The CO_2 content of the arterial blood diminishes and later increases above the normal value. Differences in the rabbit, dog and man were only of minor importance, *e. g.*, compensation occurred latest in dogs. There was an increase of H ions in the urine. After narcosis, the blood sugar is abnormally high. Glucosuria appears only seldom and acetoneuria never. Essentially the same phenomena were observed in $CHCl_3$ narcosis. The effects of shock, loss of blood and nutrition on the factors governing acid-base economy were investigated. C. C. DAVIS

Influence of hydrochloric acid and sodium bicarbonate on the tension of the abductor muscle of valves of anodon. M. DU BUISSON. Univ. Ghent. *Arch. intern. physiol.* 29, 11-8(1927); *Physiol. Abstracts* 13, 21.—HCl hinders while $NaHCO_3$ brings about relaxation of the abductor muscles of valves of anodon when nervous stimuli are abolished. H. J. DEUEL, JR.

The influence of adrenaline and ergotamine on chronaxie of muscle. J. BEERENS AND I. VAN DEN BERGHE. Univ. Ghent. *Arch. intern. physiol.* 29, 25-30(1927); *Physiol. Abstracts* 13, 21. H. J. DEUEL, JR.

Physiological action and stability of halogens in compounds. K. KINDLER. *Arch. Pharm.* 266, 394-406(1928).—An address. W. O. F.

Chemical composition and therapeutic action. EMANUELE OLIVERI-MANDALÀ. *Atti congresso naz. chim. pura applicata* 2, 903-7(1926).—A review. L. T. F.

Chemotherapy of epizootic lymphangitis by mercuric biiodide. G. JEAUME. *Maroc. Medical* 1928, 15; *Rev. Hyg. Med. Prev.* 50, 554(1928).—Favorable results from HgI_2 in the treatment of lymphangitis in mules were obtained. The intravenous injection of aq. HgI_2 , 2 parts per 1000, for 3 weeks was carried out. Each animal received a total of 2 g. of HgI_2 in 15 injections. All the mules completely recovered. C. R. F.

The influence of toxic substances on the nitrogenous and purine metabolism by dogs. Y. OKURA. *Tseng. Japan J. Med. Sci. Pharm.* 1, 49-74(1926); *Physiol. Abstracts* 13, 46.—Thyroid feeding accelerated purine metabolism more strikingly than it accelerated general N metabolism. Injection of certain bacterial products had, with small doses, a similar effect, but with large doses increased general N metabolism more than metabolism of purine bodies. H. G.

Acid therapy with neutral salts. F. MAINZER. *Klin. Wochschr.* 6, 1689-91(1927); *Physiol. Abstracts* 6, 1689-91.—A lecture on the uses of neutral salts in promoting acidity of the urine, lowered blood pH , and diminished alkali reserve. Special attention is devoted to the use of NH_4Cl , and data showing the extent of its effects are given. The delay in the excretion of Cl ion compared with NH_3 is attributed to a water retention in the tissues which follows the initial diuresis. The water passing into the tissues takes chloride with it. H. G.

Action of synthetic thyroxine. F. HAFNER. *Klin. Wochschr.* 6, 1932-5(1927); *Physiol. Abstracts* 13, 44.—The expts. were carried out with thyroxine synthesized by Schoeller and K. Schmidt. It was found that the prepn. accelerated the metamorphosis of tadpoles and axolotls. In mice a subcutaneous injection of 0.003 mg. per g. increased the resistance to acetonitrile to the same extent as 0.5 mg. per g. of dried thyroid gland. The O consumption of rats was markedly increased and a diuresis was produced in rabbits. Cyanide does not inhibit the accelerating influence of thyroxine on metamorphosis in tadpoles or axolotls. Because of this the author suggests that thyroxine acts on anaerobic oxidation processes. H. G.

Homeopathic indications of iodine in the light of present day research. PAUL S. WYNE. *J. Am. Inst. Homeopathy* 21, 549-61(1928).—A review of the physiol. action and therapeutic use of I and its compds. with bibliography. JOSEPH S. HEPBURN

The effects of ether anesthesia on the composition of the blood and the relation to thyroid function. H. E. MAGEE, W. ANDERSON AND A. E. GLENNIE. *Brit. J. Exptl. Path.* 9, 119-27(1928).—The blood of rabbits was examd. before and during ether anesthesia in normal, thyroid-fed and thyroidectomized animals. The inorg. P was lowest in March and April and highest in June and July. Ether anesthesia in normal animals lowered the Ca but increased the inorg. P, sugar and pH , the latter tending to return to normal after a time. Increasing doses of thyroid first raised and then lowered the sugar. Thyroid feeding progressively, and thyroidectomy slightly,

diminished the hyperglucemic response to ether. Large doses of thyroid increased the p_H and inorg. P which were still further raised by ether anesthesia. The effects of thyroidectomy alone and of thyroidectomy and ether on the p_H and inorg. P were variable. Thyroid feeding raised and thyroidectomy lowered the I. This was unaffected by ether anesthesia in normal and thyroid-fed and probably also in thyroidectomized animals.

HARRIET F. HOLMES

Yatrene therapy. JOSEF HAVLÍK. *Casopis Československého Lékárnictva* 6, 17-8 (1926).—A report of the phys. and chem. properties and therapeutic action of the German synthetic "Yatrene" (iodoxyquinolinesulfonic acid).

WILLIAM J. HUSA

The effect of insulin upon polyuria in diabetes insipidus; the combined effect of insulin and pituitrin upon water metabolism. O. KLEIN AND H. HOLZER. *Deut. Arch. klin. Med.* 156, 111-21 (1927).—The attempt has been made to employ for differential diagnosis the effect of insulin upon the diuresis of diabetes insipidus; but there is not sufficient justification, since the hypo- and hyperchloremic forms are not so easily distinguished by their reaction to insulin alone. In those cases where insulin alone was observed to be without diuretic effect, the effect became manifest when pituitrin was injected with the insulin. The antidiuretic effect of insulin is then an intensification of the effect of the pituitrin. In a case of syphilis where the hypophysis was seriously affected the antidiuretic effect was entirely lacking when insulin alone was administered; in similar cases which did not involve the hypophysis the effect was definite. In a case of lesion of the hypophysis the diuretic effect was observed only when insulin and pituitrin were injected together. The results were influenced quantitatively by the size of the dose, and by the amounts of water and of carbohydrate consumed during the expt. The use of insulin produces perfectly regular results where carbohydrate metabolism and the water-binding ability of the organism are seriously disturbed. The effect of the insulin is upon the carbohydrate metabolism, and only indirectly upon the diuresis.

P. V. JACKSON

Hypoglycemia with adrenaline. H. ROSSELLI AND E. RODRIGUEZ. *An Fac Med. Montevideo*, April, 1926; *Rev. sud-americana endocrinol. immunol. quimol. terap.* 10, 584-5 (1927).—Hypoglycemia was produced by adrenaline injections in some cases of severe tuberculosis. It was sometimes accompanied by hypoglycemic symptoms which disappeared on ingestion of hydrocarbons.

MARY JACOBSEN

The question of rat "bartonellas." E. LAUDA AND F. MARCUS. *Univ. Vienna Centr. Bakt. Parasitenk. I. Abt.* 107, 104-14 (1928).—"Bartonellas" or erythrocyte inclusion bodies appear in rats poisoned with tolylenediamine, pyridine or phenylhydrazine. Hemolysis due to the injection of distill. water, or the administration of saponin did not cause them. The inclusions are always accompanied by either anemia or erythrocyte degeneration. Apparently they are not parasitic in nature.

The influence of temperature on the biologic action of x-rays. A. DOCKNON. *Arch. Phys. Therapy, X-Ray, Radium* 9, 55-9 (1928).—Using *Ascaris* eggs as test material there was found to be little variation in the percentage of embryos injured within a temp. range of 5-20°. From 20° to 47° the number injured increased rapidly with the temp. D. explains the phenomena by considering that the biol. reaction consists of 2 parts, a photochem. reaction which does not vary with temp., and an ordinary chem. reaction which varies rapidly with temp. The second precedes and makes possible the first.

E. H. QUIMBY

The rate of action of drugs and ions on frog heart. PREMANKUR DE. *Univ. of Edinburgh. J. Pharmacol.* 33, 115-28 (1928).—Strips of frog ventricle were subjected to perfusion with Ringer soln. and certain modifications of Ringer soln. The response of the ventricle to induction shocks under different conditions was noted. With Ca-free Ringer or with Ringer soln. contg. 0.09% K, there occurred a 50% reduction in beat in 3 seconds. Recovery in normal Ringer was more rapid. With high frequency of stimulation the action with K is even more rapid, while differences in frequency of stimulation does not affect the response to Ca-free Ringer. With Ringer soln. at p_H 6.0 several minutes were required to reduce the rate $1/2$. Recovery was frequently incomplete. With greater frequency of stimulation the action was more rapid. Similar results were obtained by the addition of NaCN to the Ringer soln.

C. RIEGEL

Comparative antiedemic efficiency of adrenaline and related amines and pituitary in experimental edemas. M. I. TANTER. *Stanford Univ. J. Pharmacol.* 33, 129-46 (1928).—Injections of epinephrine prevented or benefitted the edema produced in cats and in rabbits by *p*-phenylenediamine, prevented or greatly diminished dionine chemosis in cats, mustard oil chemosis and mustard oil dermatitis in rabbits. Phenylethanolamine caused a delay in onset of *p*-phenylenediamine edema, and a decrease in dionine chemosis, but was ineffective in mustard chemosis or dermatitis. Pituitrin had no

antiedemic effect on edema of paraphenylenediamine, but prevented dionine and mustard-oil chemosis, and mustard dermatitis. Tyramine and ephedrine were not beneficial in any of the 4 types of edema. C. RIEGEL

The sequence of events in the excitation of the respiratory center by caffeine and some other stimulants. RALPH G. SMITH. Washington Univ. *J. Pharmacol.* **33**, 147-65(1928).—S. was able to study the effect of drugs on unanesthetized dogs, samples of alveolar air being collected by a specially devised method at the same time the rate, rhythm and minute volume of respiration were recorded. Caffeine caused an increase in ventilation which usually began 1 min. after injection, and lasted 2 to 10 min. Alveolar CO_2 tension was reduced, the max. depression occurring after the respiratory ventilation had returned to normal, and lasting sometimes as long as 2 to 3 hrs. α -Lobeline given intravenously caused a great increase in respiration beginning 30 sec. after the injection and lasting 2 to 3 min. Alveolar CO_2 tension was decreased and returned to normal in 10 min. With subcutaneous injections the effects were slower to develop and were more lasting. Cardiazole caused an increase in ventilation with a simultaneous decrease in alveolar CO_2 tension. C. RIEGEL

Tolerance and cross-tolerance in the human subject to the diuretic effect of caffeine, theobromine and theophylline. NATHAN B. EDDY AND ARDREY DOWNS. Univ. of Alberta. *J. Pharmacol.* **33**, 167-74(1928).—Caffeine, theobromine and theophylline were given by mouth to three normal individuals accustomed to drinking coffee. The urinary output was measured and the minimal effective diuretic dose detd. The same individuals abstained from coffee for one month, and were then subjected to a similar expt. The results indicated an increased tolerance to the three drugs was produced by the habitual use of coffee. The reaction time was shortened in individuals tolerant to the diuretic action of the drugs, while in those not tolerant the reaction time was lengthened. C. RIEGEL

A comparison of the pharmacological action of diacetone alcohol and acetone. D. C. WALTON, F. F. KEHR AND A. S. LOVENHART. Univ. of Wisc. *J. Pharmacol.* **33**, 175-83(1928).—Rats were injected intravenously with acetone and with diacetone alcohol (dimethylacetonylcarbinol). The max. tolerated dose of the alcohol was 3 cc. per kg., as compared with 5 cc. of acetone, while the m. l. d. was 3.25 cc. per kg., as compared with 6-8 cc. of acetone. Rats receiving alcohol showed less irritation and more immediate soporific effect than those receiving acetone. In rabbits and dogs the alcohol had a depressant action on respiration and produced narcosis, the extent of the latter depending on the dose and mode of administration. Both acetone and alcohol produce a fall in blood pressure in anesthetized dogs and rabbits, the extent of the decrease varying with dosage, speed of injection and strength of soln. C. RIEGEL

Biochemical study of thiourea. E. NICOLAS AND J. LEBDUSKA. *Compt. rend.* **186**, 1441-3(1928).—Thiourea, according to its concn, retards or prevents the coagulation of the blood *in vitro*. At a concn. of 3% thiourea the blood remains fluid, while urea up to 3.5% does not modify the time of coagulation, and at 4.5% simply retards the phenomenon. Thiourea is but slightly toxic. Introduced into the duodenum of the dog in doses of 1 g. per kg. of body wt. it does not modify the blood pressure or respiration. It has a moderate diuretic action and increases the output of bile if injected into the duodenum but not if intravenously injected. L. W. RIGGS

Differential vasodilator action of cobalt and nickel chlorides. J. M. LE GOFF. *Compt. rend.* **186**, 1656-7(1928); cf. *C. A.* **22**, 1403.—Intramuscular injections of NiCl_2 failed to produce vasodilatation in rabbits or man. Although Co and Ni are about equally toxic, their physiol. action on the vessels was very different. L. W. RIGGS

Influence of the blockage of Kupffer cells on the resistance of the liver with reference to an hepatotoxic substance. MAURICE PANISSET. *Compt. rend. soc. biol.* **98**, 1520-1(1928).—The blockage of the reticulo-endothelial system of the dog by 2 injections 24 hrs. apart of 0.3 to 0.5 cc. per kg. of India ink prevented a fatal action of 0.08 g. per kg. of novarsenobenzene injected 48 hrs. later. When the test by the elimination of rose bengale shows no defect in the chromogog function, the dog withstands without incident a dose which would be fatal in the animal with an impaired chromogog function. L. W. RIGGS

Action of magnesium chloride on guinea pigs with scorbutic deficiency. PIERRE DELBET AND PALIOS. *Compt. rend. soc. biol.* **98**, 1534-5(1928).—Animals on the Randoïn scorbutic diet were given daily injections of 5 cc. of 1.21% MgCl_2 for 8 days, then 50 cc. daily of the same soln. mixed with the food. Five animals thus treated lived 9, 13, 14, 21 and 25 days, resp., while of 6 controls 2 lived 4 days, 2 lived 8, one 12 and one 18. The explanation offered is that MgCl_2 permits or regulates certain syntheses which the absence of the antiscorbutic vitamin prevents or modifies. Since the controls

were not entirely deprived of Mg it is proposed that the usual Mg content of foods should be supplemented by addnl. Mg salts as is the case with NaCl. L. W. RIGGS

Action of sugars on muscular rigidity produced by monobromoacetic acid. THALES MARTINS. *Compt. rend. soc. biol.* **98**, 1558-60(1928).—Sugars promote the condition of rigidity caused by $\text{CH}_2\text{BrCO}_2\text{H}$. Sucrose is most and lactose least efficient in this action. L. W. RIGGS

Action of antipyretics on glucemia. ALBERTO DE CARVALHO. *Compt. rend. soc. biol.* **98**, 1583-6(1928).—Quinine, pyrimidone and antipyrine administered intravenously reduce the blood sugar of healthy subjects and of diabetics sometimes as much as 50%. This effect is most pronounced about 2 hrs. after the injection and it persists for several hrs. L. W. RIGGS

Action of glukhormont upon adrenaline glucemia. CARLOS TRINCAO. *Compt. rend. soc. biol.* **98**, 1602-4(1928).—Three fasting diabetics were treated as follows. The glucemia was detd. before and each 30 min. after the injection of 1 mg. of adrenaline. Three hrs. later 1 mg. of adrenaline and 3 glukhormont tablets were administered simultaneously and the glucemia detd. as before, when nearly every detn. showed that the glucemia was less than that following adrenaline alone. After 4 days of treatment with 4 tablets daily of glukhormont, 1 mg. of adrenaline was administered and the glucemia detd. at each 30 min. following when it was found to be from 3 to over 20% less than after adrenaline alone. L. W. RIGGS

Action of some substances of the camphor group on *Ascaris lumbricoides* of swine. S. F. GOMES DA COSTA. *Compt. rend. soc. biol.* **98**, 1604-6(1928); cf. *C. A.* **21**, 2332. —The introduction of the imide function into the radical of camphoric acid increases the toxicity of the latter. Camphocarbonic acid appears always inactive toward *Ascaris*. The introduction of CO_2H into the camphor mol. renders this compd. inactive toward *Ascaris*. Campholene nitrile prepd. as a fine emulsion and in concns of 0.005 M was slightly active toward worms. L. W. RIGGS

Action of ergotamine on the gastric secretion. EDUARDO COELHO and J. CANDIDO DE OLIVEIRA. *Compt. rend. soc. biol.* **98**, 1608-11(1928).—Fasting persons were subjected to stomach lavage before commencing the expts. The total gastric acidity at the end of each of 5 consecutive 15-min. periods after a test meal was equiv. to 15, 25, 30, 34 and 34 cc. of 0.1 N NaOH, resp. After the same test meal and an injection of 1 cc. (0.0005 g.) of ergotamine the corresponding figures were 27, 55, 70, 72 and 60. The total HCl without ergotamine was 10, 16, 20, 22 and 20 cc.; with ergotamine the figures were 19, 42, 50, 54 and 50 cc. L. W. RIGGS

Blood modifications following intravenous injections of India ink. T. TURCU. *Compt. rend. soc. biol.* **98**, 1620-2(1928).—Injections of India ink immediately increased the time of coagulability of the blood, decreased the complement titer and increased the velocity of sedimentation of the red corpuscles. These variations persisted from 24 to 48 hrs. and were followed by a return to normal. L. W. RIGGS

Increased action of insulin in experimental renal impermeability. M. LOEPER, A. LEMAIRE and J. TONNET. *Compt. rend. soc. biol.* **99**, 19-20(1928).—Expts. with rabbits in which one or both kidneys were ligated showed a progressive increase in the hypoglycemic power of insulin. **Action of insulin in renal impermeability in man.** M. LOEPER, RAVIER and TONNET. *Ibid.* 20-1.—By the administration of 5 to 10 units of insulin the av. lowering of the glucemia in 7 normal subjects was about 20%; in 6 patients with cardio-renal insufficiency the lowering was 42% and in 7 cases of renal impermeability the lowering was 45%. Insulin should be administered with caution to patients with defective renal permeability. L. W. RIGGS

Is there an antagonism between the water-soluble extract of the anterior lobe of the hypophysis and folliculine? L. BROUHA. *Compt. rend. soc. biol.* **98**, 43-4(1928).—The precocious puberal state brought about by the injection of folliculine is not prevented in rats by the simultaneous injection of the water-sol. ext. of the anterior lobe of the hypophysis. L. W. RIGGS

Action of nicotine on the excitability of motor nerves. H. L. MAZOUÉ. *Compt. rend. soc. biol.* **99**, 50-2(1928). L. W. RIGGS

Quantitative study of the action of histamine on the excitability of the cardiac inhibitory fibers of the vago-sympathetic nerve. A. B. CHAUCHARD and P. SARADINCHVILL. *Compt. rend. soc. biol.* **99**, 53-5(1928).—Expts. with dogs showed that the injection of histamine gradually increased the chronaxie which gradually returned to its normal value. L. W. RIGGS

Insulin and its relation to ovulation. C. COTTE and (MLLE.) G. PALLOT. *Compt. rend. soc. biol.* **99**, 74-5(1928).—Expts. with rats indicate that insulin retarded the appearance of the estrus and prolonged the period of genital inactivity. L. W. RIGGS

Hypotensive action of adrenaline in tabetics. A. DUMAS, ROGER FROMENT AND (MILÉ) MERCIER. *Compt. rend. soc. biol.* 99, 76-8(1928).—In the 3 cases studied the subcutaneous injection of 1 mg. of adrenaline was followed by a fall of 7.5 cm. of Hg in the blood pressure. The pulse was only slightly altered.

L. W. RIGGS

Effect of liquid petrolatum given by mouth on digestion and absorption of food. ALFRED B. OLSEN. *J. Am. Med. Assoc.* 91, 143-7(1928).—The results of expts. with dogs and men indicated that liquid petrolatum by mouth in therapeutic doses did not interfere with the digestion and absorption of protein and carbohydrate food.

L. W. RIGGS

Growth-producing effects of extracts of tobacco on mice. FERDINAND C. HELWIG. *J. Am. Med. Assoc.* 91, 150-1(1928).—Tobacco tar obtained at temps. produced by smoking pipes did not appear to contain any carcinogenic factor capable of producing limitless growth of epithelium in mice. The tar causes ulceration which heals promptly on removal of the irritant. Combustion products obtained at 400° to 500° act similarly to those formed in pipe smoking. Tobacco tar mixed with olive oil appeared to cause epithelial proliferation, but the growth was limited and disappeared by spontaneous involution.

L. W. RIGGS

Hypoglucemia-producing material from plants and microorganisms. YOSHIO SHIKINAMI. *Tôhoku J. Exptl. Med.* 10, 560-79(1928); *C. A.* 22, 1604.—From *Aspergillus ozyzac*, baker's yeast, beer yeast, bark and leaves of *Taxus cuspidata* and leaves of *Pinus densiflora* exts. were prepd. which, in rabbits, caused a gradual lowering of the blood sugar followed by a gradual return to normal in about 48 hrs. In 8 of the 34 animals tested there were hypoglucemic convulsions when there was a notable disappearance of glycogen from the liver and skeletal and heart muscles. There was also a moderate diminution of liver fat but not of the skeletal muscle fat. Histologic changes were evident in the liver but not in the suprarenals or pancreas. The passage of the hypoglucemic principle from one animal to another was not proved. Hypoglucemia-producing exts. were obtained from various bacteria and cocci. Exts. of sugar-splitting bacteria caused the blood sugar to diminish. Exts. of other bacteria were without action.

L. W. RIGGS

Relation between chemical constitution and pharmacological action of phenanthrene alkaloids. ITARO KIKUCHI and TOYOKICHI TAKASE. *Tôhoku J. Exptl. Med.* 10, 580-5(1928).—Chemically inactive atomic groups increase the convulsant action of the phenanthrene alkaloids, whereas the chemically active groups increase the narcotic action. The active and inactive groups interfere with each other so as to decrease their properties. The alkaloids studied were morphine, apomorphine, codeine, dihydrocodeine, oxycodone, hydroxycodone, sinomenine, bulbocapnine, thebaine and domesticine methyl ether.

L. W. RIGGS

Paralyzing action of magnesium salts on the Auerbach plexus. ITARO KIKUCHI. *Tôhoku J. Exptl. Med.* 10, 586-9(1928); cf. To, *C. A.* 15, 2501.—Expts. with rabbits proved that $MgCl_2$ exerts no irritating action on the sympathetic endings of the uterus and probably not of the stomach.

L. W. RIGGS

The effect of ceanothyn upon the kidney and liver of the dog. THEODORE KOPANYI. *J. Am. Pharm. Assoc.* 17, 528-9(1928).—Ceanothyn, administered orally to dogs in doses 30-40 times the daily human dose, over a period of 17 days produced no detectable impairment of the kidneys and liver in the dog as shown by functional test and morphological studies.

L. E. WARREN

The toxicity of an impurity of official cinchophen. ROBERT A. HATCHER. *J. Am. Pharm. Assoc.* 17, 557-63(1928).—Cinchophen may contain as much as 3% of γ -anilino- γ -phenylbutyric acid. Various pharmacologic tests on the cat and the dog demonstrated that the substance is only slightly toxic.

L. E. WARREN

The effect of drugs on the number of circulating white blood cells. WALTER J. R. CAMP. *J. Lab. Clin. Med.* 13, 206-14(1928).—The blood is considered as a tissue and as such, its function and activity must be under nervous control. The distribution of leucocytes in the peripheral blood is believed under the control of the autonomic system because: (1) The same blood picture is produced by such chemically different substances as pilocarpine, tartrates, eserine, arecoline, guanidine and adrenaline after a sensitizing dose of eserine. (2) The same differential blood picture is effected by substances stimulating the sympathetic nervous system, as adrenaline and by such substances as decrease the activity of the parasympathetic nerves, as atropine and calcium. (3) The pilocarpine action on the blood is promptly and completely checked by atropine just as pilocarpine action on any other organ is stopped by this same drug, and further, pilocarpine is ineffective after atropine has been given. The partition of leucocytes in the peripheral circulating blood is believed an index of

autonomic balance, the lymphocytes running parallel to parasympathetic tone and the neutrophils to sympathetic tone. The spleen plays no part in the production of a drug leucocytosis. It is possible and probable that this influence of the autonomic system is mediated through the medium of inorg. ions, such as Ca. ETHEL W. WICKWIRE

R. A. GORTNER

Autolysis of fish muscle. III. Formation of ammonia. TAKEO OYA AND KI-ITSU SUMI. *J. Imp. Fish Inst. (Tokyo)* **22**, 21-4 (1926). (In Japanese, English résumé 16-7); *Biol. Abstracts* **1**, 452.—The authors earlier reported NH_3 formation in autolyzing mackerel muscle, most rapidly at p_{H} 6. They now report studies on NH_3 formation in autolyzing muscles of *Scomber japonicus*, *Paralichthys olivaceus*, *Pagrosomus mayor*, *Euthynnus vagans*, and *Tetrapturus mitsukuri*, the amt. formed in the 1st and 4th being greatest. The muscles of the 1st, 4th and 5th contain guanase, the remaining 2 none or at most a little. H. G.

The phosphate content or renal capsular fluid in necturus. FRANCIS O. SCHMITT AND H. L. WHITE. Washington Univ. *Am. J. Physiol.* **84**, 401-6 (1928).—The glomerular fluid from the kidney of *Necturus* contained only 25% as much inorg. P as did the blood. J. F. LYMAN

The effect of insulin on the blood sugar of fishes. IRVING E. GRAY. Univ. of Wisc. *Am. J. Physiol.* **84**, 566-73 (1928).—Injections of insulin produced convulsions and reduction of blood sugar to about 33% normal in trout, menhaden and scup. Convulsions were not produced in the puffer. Possibly sluggish fish with low blood sugar have a different kind of carbohydrate metabolism than do the more active fish. J. F. LYMAN

Temperature characteristics for pulsation frequency in *Gonionemus*. E. WOLF. Lab. Gen. Physiol. Harvard Univ. *J. Gen. Physiol.* **11**, 547-62 (1928).—Physiological. C. H. RICHARDSON

Experimentally induced metamorphosis in echinus. JULIAN S. HUXLEY. *Am. Nat.* **62**, 363-75 (1928).—Treatment of advanced larvae of *Echinus miliaris* with very dil. solns. of HgCl_2 (about molar (2×10^6)) rapidly causes precocious metamorphosis, a young echinus in one case surviving 8 days even in the absence of food. This appears to be caused through the differential susceptibility of larval tissues and echinus rudiment. The former are more affected by the poison and undergo histolysis, and are then reabsorbed by the echinus rudiment. When the echinus rudiment is small, metamorphosis is less rapid and may be incomplete, both larval and echinus tissues undergoing histolysis. Even when metamorphosis in such cases is complete, it is often abnormal, the young echinus possessing small or no tube feet or spines. Parallel abnormalities are found in thyroid-induced metamorphosis in anuran tadpoles. I. W. RIGGS

Functioning of the pancreas in amphibian larvae. MAX ARON. *Compt. rend. soc. biol.* **99**, 213-5 (1928); cf. Needham, *C. A.* **21**, 2939, 3000. **Functional correlation between the thyroid gland and the endocrine pancreas in amphibian larvae.** *Ibid.* 215-7. L. W. RIGGS

The relations between the ash content as well as the degree of milling of a flour and the specific conductance of its aqueous extract. R. STRONECKER. *Z. ges. Mühlenwesen* **4**, 27-9; *Chem. Zentr.* **1927**, **11**, 341-2; cf. *C. A.* **18**, 2048.—In freshly milled wheat and rye flours, the p_{H} values of which are little different, the ash content can be estd.

fairly precisely by the cond. if the cond. curve for the particular grain has once been established. This is not possible, however, with grains of unknown origin. Bleaching with NO_2 increases the cond. in a similar way to the action of Cl . C. C. DAVIS

The specific conductance of aqueous wheat flour extract. E. BERLINER AND R. RÜTER. Univ. Frankfurt. *Z. ges. Mühlenwesen* 4, 29-32; *Chem. Zentr.* 1927, 11, 342.—Large variations in the ratio: ash content/cond. were found, even with flours of the same type (cf. Strohecker, preceding abstr.). In Sweden cultivated wheats showed remarkably low cond. The merit of cond. detns compared with the detns. of the ash lies in the rapidity of the former. C. C. DAVIS

The influence of cereal flours on the reaction of the liquid in which they are suspended. S. KOEHLER. *Bull. intern. acad. Polonoise* 1927B, 951-63 (publ. 1928).—Barley flours suspended in weak acids or bases affects the p_{H} value of the solvent. In this study, 4 g. of freshly milled rye, wheat, barley and oat flours were shaken with 80 cc. of HCl , NaOH or distd. water that had not been boiled. The flours were allowed to settle 40-60 min., and the p_{H} of the solvent was detd. During the first 15 min. of shaking, the p_{H} of the solvent changed rapidly, the acids increasing and the bases decreasing in p_{H} value. After this initial change, there was a slow definite decrease in p_{H} in all solvents, the rate varying with the kind of flours. A study of the data indicated that the p_{H} of a solvent that would not undergo the initial p_{H} change varied from 6.2 to 6.94. Since only one sample of each grain was studied, this variation may not be due to a difference in species. When barley flour that had been milled 3.5 years was added to an NaOH soln., the p_{H} decreased from 6.2 to 5.5 almost immediately, and then rapidly increased to a const. value of 5.9 after 3 hrs. The first change was probably due to certain decompn. products in the flour. AMY LE VESCONTE

Factors influencing the baking properties of flour. T. H. FAIRBROTHER. *Food Manuf.* 2, 285-6; 3, 369-70, 397-8 (1928).—The factors influencing the baking properties of flour may be summarized as chem., biochem., phys., and manipulative. The chem. factors involve the understanding of the protein content and the chem. changes which influence this content, the chem. actions which will oxidize the pigments and produce flour of standard whiteness, and those which induce the gluten to function correctly. The biochem. factors involve the life and action of yeast, the function of certain enzymes which influence the diastatic activity and provide yeast foods. The phys. factors involve a knowledge of the viscosity and colloidal properties of gluten, the size of particle, the effect of humidity during milling and storage; and finally the manipulative factors are concerned with clean milling and the handling of the flour and dough in the baking processes. A complete understanding of all these factors will lead ultimately to the real standard bread. J. A. KENNEDY

Detection of rice flour in other flours and in spices. ANON. *Pharm. Weekblad* 65, (680) 2 (1928).—The detection of rice flour particles by staining with fuchsin which reveals a characteristic network of protein (Wagenaar, C. A. 22, 1811) is difficult in the presence of ground pepper perisperm which takes the stain in much the same way. The difficulty is obviated by using a stain prepd. from 0.5 g. carmine, 25 cc. glycerol and 25 cc. 4 N NH_4OH . This gives a violet pattern with the rice granules but no color with pepper perisperm. A. W. DOX

The valuation of milk. J. GERUM. *Z. Untersuch. Lebensm.* 55, 274-83 (1928).—A discussion, emphasizing the importance of refractive index and f. p. depression in the valuation of milk. The use of *alocs* as a medicine causes a lowering of the fat content of milk. WILLIAM J. HUSA

New method for the volumetric determination of protein in milk. AL. IONESCO-MATIU AND C. V. BORDEIANU. *Bul. soc. chim. România* 9, 76-85 (1928).—For this detn. a glass-stoppered test tube is used which has a uniform bore of 1 cm., is calibrated in 0.1 cc. from 2 to 5 cm. and has marks above this showing 7.5 cc. and 10 cc. To det. the protein content in milk, fill the dry tube exactly to the 7.5-cc. mark with a soln. prepd. by dissolving 5 g. of HgCl_2 in 100 cc. of pure acetone. Not more than 250 cc. of this reagent should be prepd. at a time, as it does not keep very well. On top of the acetone soln. in the tube, add exactly 2.5 cc. of milk dropwise. Stopper the tube and shake 120 times. After 15 min. shake 30 times. Open the tube and let it stand 3-4 min. Close and allow to stand in an upright position for 24 hrs. at 18°. Read the vol. of the ppt. and multiply by 1.02 to get the wt. of protein contained in 100 cc. of milk. From the relations between fat content, d., and protein content, it is easy to tell whether a sample of milk has been watered, skimmed or both watered and skimmed. W. T. H.

Milk investigation with the aid of cryoscopy, the cryolac number and the chlorine-lactose number. J. FIEBIGER AND W. KORDATZKI. Prussian Hyg. Inst. Landsberg.

Z. Untersuch. Lebensm. **55**, 251-62(1928).—Detns. were made on the milk of cows inoculated with various diseases for serum production. The f. p. depression varied from 0.537° to 0.576°, the av. being 0.552°. The cryolac no. ranged from 393 to 435, the av. being 413. The Cl-lactose no. varied between 1.63 and 6.63. WILLIAM J. HUSA

Milk fat determination in fatty mixtures containing coconut oil. J. GROSSFELD. *Kazell* 1927, 5 pp. separate; *Chem. Zentr.* 1927, II, 184.—A general discussion together with the outlines of a method of detn. based on the butyric acid number. The details are substantially the same as given before (cf. *C. A.* **22**, 1863). A. L. HENNE

I. The effect of heat upon certain constituents of milk. II. Adult utilization from heated milk. KATE DAUM. *Abstracts of Theses, Univ. Chicago, Science Series* **4**, 423-30(1925-6) (Publ. May, 1928).—The changes of the Ca, Mg, P, CO₂ and citric acid content and of the *p_H* of cow milk brought about by heating were studied. The detns of Ca, Mg and P were made on raw milk, milk heated for 6 min. in a CaCl₂ bath, the temp. of which was 106-10°, and milk heated for 30 min. in H₂O bath which had the temp. of 100°. The samples of the heated milk were analyzed at once and after standing without agitation for 24 hrs. Heating decreased the Ca, Mg and P content, the decrease being greater in the milk heated for 30 min. Standing lowered the values still more. Citric acid and *p_H* did not change upon heating, while CO₂ was much decreased, the loss being greater for the milk heated for 30 min. Investigations on the Ca balance of 2 women whose Ca intake was mainly covered by milk showed that the balance was negative with both raw and with heated milk, though the losses on the heated-milk diet were somewhat larger. G. SCHWOCH

The effect of metals on milk. W. E. WARNER. *Food Manuf.* **3**, 398(1928)

J. A. KENNEDY

The composition of milk of western Hungary. ST. SZANYI. *Z. Untersuch. Lebensm.* **55**, 207-8(1928).—Analytical data are given. WILLIAM J. HUSA

Studies on starters. B. W. HAMMER AND M. P. BAKER. *Id. Agr. Expt. Sta. Research. Bull.* **106**, 135-56(1928).—The results obtained when starters were made from milk pasteurized with different exposures showed that milk heated to 145° F. for 30 min. developed acid and coagulated more slowly than milk heated to considerably higher temps. Essentially the same rate of growth of the starter organisms occurred after heating to 160° F. for 30 min. as when a higher temp. was used for this period. With a heating time of 30 min. the influence of the heat seemed to be gradual and spread over a considerable temp. range, instead of occurring completely at a definite temp. The explanation of the variations noted in the rate of coagulation following different pasteurization exposures undoubtedly lies in the effect of the heat on the germicidal property of milk. The data obtained suggest that, if uniform conditions for the growth of starter organisms are to be provided from day to day, the pasteurization exposure used must be taken into account. C. R. FELLERS

A colorimetric method for the determination of coloring substances in butter (butyrolcolorimeter). JANUSZ KRÓLIKOWSKI. *Landwirtschaftl. Hochschule Warsau Roczniki Nauk Rolniczych i Lesnych* **16**, 21-6; *Chem. Zentr.* 1927, II, 345. The color of melted and filtered butter is compared with the color of an aq. indicator soln. of tartrazine to which sulfanilic acid and β -naphthol have been added. The app. is described. C. C. DAVIS

Preliminary investigations into the factors that affect the keeping qualities of acidified butter. E. HAGLUND AND E. WALLER. *Medd. Centralanstalt. forskningsenhet. jordbruks No.* **321**, Mejeriförsök No. **33**, 3-21(1927).—The object of the investigation by H. and W. was to det. how butter was affected by the acidity of the cream, salt and bacteria introduced. Approx. 50 dairies cooperated. The acidity was expressed in Soxhlet-Hemkel degrees. One cc. of a 0.6% HgCl₂ per 100 cc. cream was added as a preservative during transportation from dairy to main lab. Three observations were made in 1 yr.: March 20, Aug. 2 and Nov. 6 (periods 1, 2 and 3, resp.). The results indicate a relation between the acidity and the quality of the butter. The butter made from cream of high acidity was of better quality at the end of 10 days but deteriorated faster than that made from cream of lower acidity. The acidity was highest during the 2nd period. The acidity of the moisture in the butter decreased with age while that of the butter fat increased. No definite data on the effect of salt on the keeping quality of butter were obtained. A discussion regarding the types of bacteria present is given but no conclusion drawn on the possible effects of these on the quality of the butter. O. A. NELSON

Alimentary egg pastes. GIOVANNI ISSOGLIO. *Atti congresso naz. chim. pura applicata* **2**, 1023-4(1926).—I. recommends the analytical detn. of the lecithin P₂O₅ as an index of the degree of admixture of grain flour in egg pastes. L. T. F.

Scientific control in the cocoa and chocolate industries. H. W. BYWATERS. *Food Manuf.* 1, 37-40(1927); cf. *C. A.* 22, 3000. E. J. C.

Cacao tannin and its determination. H. R. JENSEN. *Analyst* 53, 365-72(1928).—The results indicate that the water-sol. tannin content of full roasted cacao nibs ranges from 5.2 to 6.5%, corresponding to 13.8% in the fat-free and dry cacao. Compared with the tannin contents of tea and coffee it is surprising that the taste of the cacao is not more astringent. Fine, mild, Ceylon cacao beans contained as much tannin as the stronger Accra and Trinidad beans. W. T. H.

Determination of the color-producing constituents of the cacao bean. WILLIAM B. ADAM. *Analyst* 53, 369-72(1928).—By using a suitable sequence of solvents, it has been found that the unfermented cacao bean contains (a) a substance belonging to the catechin series; (b) a catechu tannin; and (c) a compd. of cacao tannin and caffeine. The red and brown coloring matters are complex alteration products of the catechin and tannin originally present in the bean. Methods previously proposed for detg. the catechin-like substance and the cacao tannin were studied and modified until fairly consistent results were obtained in the classes of cacao under examn. From the analytical results it is apparent that cacao catechin undergoes alteration during the process of fermentation and in the completely fermented bean no catechin is present. The alteration of the tannin appears to be less drastic. W. T. H.

The sanitary valuation of meat. L. M. HOROWITZ-WLASSOWA. *Bact. Med. Inst. Ekaterinoslaw (Ukraine). Z. Untersuch. Lebensm.* 55, 239-46(1928).—The alk. or acidity of aq. meat ext., the p_H , the refractive index, the biuret reaction, the total N, the N of the tannin and phosphotungstic acid ppts., the oxidizability, and the I absorption value give no indication as to the freshness of meat. Eber's reaction frequently gives negative results in samples showing incipient decompn. The test for NH_3 with litmus paper, the meat being heated with NaOH or MgO, is of no practical value, since NH_3 is split off during the test. The heating of meat ext. (ground meat in NH_3 -free H_2O) for 5 min. with the addn. of MgO at 50° liberates NH_3 from NH_4 salts but does not split it off from amino acids. With litmus paper, this test is sensitive to 0.02% NH_3 . Fresh meat does not give a positive test. The titration of amino acids by Sorensen's method gives useful indications as to the freshness of meat but it is not as simple as the above test since it requires the prepn. of aq. exts. W. J. H.

The aseptic autolysis of frozen meat. C. COLELLA. *Boll. soc. ital. biol. sper.* 3, 320 1(1928).—The aim of the investigation was to ascertain whether frozen beef from America under the conditions which the consumer finds it on the market is more susceptible to autolysis than fresh meat bought likewise. Fourteen samples were tested, 7 of each. There are no substantial differences in the intensity of autolysis between fresh and frozen beef; in both, 30 days after aseptic autolysis at 38° there was about 20% of the total N in soln. The curve of autolysis is the same for both kinds of beef. PETER MASUCCI

A method of differentiating different types of cooked meat by the precipitin reaction. RAHEL ROSENBERG. Charkow-Ukraine. *Centr. Bakt. Parasitenk. I Abt.* 107, 448-59(1928).—The precipitins from unheated meat are different from those produced by heated meat. Hence rabbits must be injected with exts. of cooked meat to detect the latter. JOHN T. MYERS

Absorption of iodine by fresh and by tainted meats. K. KATRANJIEFF. *Compt. rend. soc. biol.* 99, 112-5(1928).—**Biochemical factors in the absorption of iodine by tainted meats.** *Ibid.* 115-8. The essential factors which intervene to increase the absorption of I by filtrates of aq. macerations of tainted meats are (a) the proteins of which the quantity increases with the alteration of the meat, (b) proteolytic products of putrefactive organisms such as amino acids, NH_3 and H_2S , (c) the bacteria themselves and products of their sol. secretions. L. W. RIGGS

Mecklenburg canned sausage. ERNST VOLLHASE AND SIEGFRIED-OTTO SCHMECHEL. *Pharm. Zentralhalle* 69, 417-26, 434-7(1928).—From the examn. of a large no. of samples prepd. and handled in Mecklenburg it appears that the excess water content detd. via Feder after a storage period of 4 months reached a max. of 30%, although the av. run was under 28%. An excess water content of 30% (stipulated amt. for Mecklenburg is 20%) clearly indicates a "stretching" of the sausage mass. The sausage liquor invariably contained protein, in amt. relatively small when compared with the liquid itself, but of sufficient importance when considered in connection with the ratio of brine to sausage. Since the protein of this canning liquor has its source in the sausage mass, the amt. of original fat-free material would be diminished by the amt. of dissolved protein, a fact which would render the excess water content too high and hence require appropriate correction. The corrected excess water content represents the apparent

value detd. *via* Feder when curtailed by five times the amt. protein dissolved out of 100 g. of sausage. The processes underlying the interchange of inorg. substances between the sausage mass and its surrounding liquor are by no means uniform, consequently the original content of inorg. constituents in the sausage mass cannot be detd. In the authors' expts. losses of such constituents in the sausage mass were estd. as high as 40%. Of unquestioned influence in this connection is the degree of permeability of the sausage casing as affected by the manner of curing. W. O. E.

The influence of onions and garlic on the growth of bacteria in sausage. E. DANIELSEN. Univ. Rostock. *Z. Untersuch. Lebensm.* 55, 291-4(1928).—The addn. of garlic or onions to sausage in any practically endurable amt. does not influence the growth of putrefactive or disease-producing bacteria. WILLIAM J. HUSA

The relation between the digestibility of fish cooked by different methods and its water content. B. GLASSMANN. *Z. Untersuch. Lebensm.* 55, 231-5(1928).—Fish cooked by the "dry heat" process contained more H₂O and was more digestible in artificial gastric juice than that cooked by the "boiling oil" method. The presence of fat lowers the rate of digestion in a mechanical way by decreasing the contact between the substrate and the aq. enzyme soln. WILLIAM J. HUSA

The alimentary value of rice and of the principal foods. L. BORASIO. *Giornale risicoltura* 18, 67-70(1928); cf. *C. A.* 22, 1633, 2187.—Analyses, giving H₂O, fats, crude cellulose, ash, carbohydrates, crude protein, calorific values and stomachic digestibilities, are tabulated for 5 types of uncooked rice, boiled rice, bolted wheat, gluten and corn flours, whole wheat, corn and rye breads, powdered sugar, cauliflower, lettuce, cooked asparagus, potato, spinach, kidney beans and peas, apples, cherries, roast beef, beef steak, roast chicken and duck, boiled milk, salmon and chicken eggs. A. R. M.

Vitamin B found in all three parts of rice kernel. HILDA M. CROLL. Illinois Agr. Expt. Sta., *Rept.* 1927, 263-4.—Whole unpolished, or "brown" rice, and both the endosperm and embryo ends of the unpolished rice kernel have been found to contain vitamin B. The embryo end seemed to be richer in vitamin B than the endosperm end of the rice kernel. Not all of the vitamin B was contained in the germ of the rice kernel, as has been found to be true of the corn kernel. Since the outer bran coats are retained in the unpolished rice kernel, the presence of vitamin B in the endosperm end may possibly be due to its presence in bran, rather than in the endosperm itself. E. F. S.

The prolamine of wheat. R. HERZNER. Chem. Lab., Hochschule Bodenkultur Wien. *Z. Untersuch. Lebensm.* 55, 262-74(1928).—By use of different alc.-H₂O mixts., H. extd. proteins from wheat which were sepd. into two main distinct groups. Further differentiation has not yet been accurately accomplished. WILLIAM J. HUSA

Apple by-products and cull utilization. CARL R. FELLERS. *Fruit Products J. and Am. Vinegar Ind.* 7, No. 11, 8-9(1928).—"An insight on a number of apple products that can be made successfully in cider mills—blending apples for a desirable quality of cider." J. A. KENNEDY

Changes produced in apples by the use of cleaning and oil-coating processes. J. R. NELLER. *J. Agr. Res.* 36, 429-36(1928).—Storage tests were made of Winesap and Delicious apples grown under irrigated conditions. Both varieties were tested in an untreated condition, dry-brushed and oil-coated, and dipped in HCl. Oil coating was the most beneficial means of improving the keeping qualities. After 4 months' storage the untreated Winesap apples respired CO₂ at a rate about 40% faster than the dry-brushed oil-coated fruit, and after 8 months storage the respiration was 17% faster. Untreated Delicious apples respired 46% faster than oil-treated ones after 4 months' storage, and 43% faster after 8 months. When exposed to room conditions the uncoiled apples lost weight at a moderately faster rate than the oiled ones. Oiling also tends to reduce the rate of shriveling and softening. An oil film of the character used caused no significant difference in the dessert quality of the fruit. Dipping in 2% HCl for 10 min. had little effect on the subsequent respiration of CO₂; 2% NaOH slightly increased respiration and rate of loss of wt. Brushing the fruit caused a more rapid respiration and loss of wt. M. S. ANDERSON

Jelly strength measurement of fruit jellies by the Bloom gelometer. CARL R. FELLERS and FRANCIS P. GRIFFITHS. *Ind. Eng. Chem.* 20, 857-9(1928).—The modifications and the conditions under which pectin and fruit jellies are best measured by a modified Bloom gelometer are described. Jellies of good consistency tested between 60 and 100 g. Jelly strength ranged from very weak (30 g.) to very tough (200 to 280 g.). The jelly strength decreased rather uniformly with increase of temp. between 10° and 30° and increased with length of storage, the max. change occurring very soon after making. The probable error of any series was within 3 g. The av. deviation between top and bottom readings for 22 series was approx. 5%. C. H. BADGER

Pectin and conserves. GIOVANNI ISSOGLIO. *Atti congresso naz. chim. pura applicata* 2, 1025-9(1926).—A discussion of the application of commercial pectin in the manuf. of jellies. Analyses of various fruits show some to have abundant pectin while others are deficient in this respect. Some commercial preps. of pectin are decidedly deficient in pectin substance. The method of analysis consists in pptg. the pectin with an excess of 96% EtOH, washing with the latter and weighing. From this weight the ash and also the protein must be subtracted in order to obtain a correct figure. L. T. F.

The determination of hydrocyanic acid in lima beans with particular attention to the p_H most favorable for the hydrolysis of the glucoside. S. KÜHNEL HAGEN. *Z. Untersuch. Lebensm.* 55, 284-91(1928).—Treat 50 g. of the finely ground beans for 3 hrs. in a closed 2-l. flask with 400 cc. of a citrate-NaOH buffer of p_H 5.92, prepd. according to Sørensen. Then add 50 cc. of a 30% tartaric acid soln. and steam-distil with the outlet of the condenser dipping into a mixt. of 50 cc. H_2O and 1-2 cc. 2 N NaOH. Collect 250 cc of distillate, add 1 g KI and titrate with 0.05 N $AgNO_3$ soln. The detn. is accurate to 0.1 mg. HCN.

The determination of the ash constituents of honey. E. ELSER. *Swiss Dairy and Bact. Inst., Liebefeld. Z. Untersuch. Lebensm.* 55, 246-51(1928).—Details are given for the detn. of the ash constituents of honey by the following methods. H_3PO_4 is pptd. by a reagent contg. strychnine and molybdic acid, and compared with a standard soln. in a nephelometer. Fe and Mn are detd. colorimetrically, Fe as thiocyanate and Mn as permanganate. Ca is pptd. as oxalate, the ppt. dissolved in H_2SO_4 and titrated with $KMnO_4$. To detn. Cl, 2 to 3 g. of honey is treated with concd. HNO_3 , 0.01 N $AgNO_3$ is added, the mixt. warmed with perhydrol, dild with H_2O , and the excess Ag titrated with NH_4CNS . K is pptd. by Na cobaltinitrite reagent and titrated with $KMnO_4$.

WILLIAM J. HUSA

The role of viscosity in heat penetration—heat penetration in sugar solutions. M. A. JOSLYN. *Fruit Products J. and Am. Vinegar Ind.* 7, No. 9, 16-9; No. 10, 22-4; No. 11, 13-5; 18(1928).—It is possible to make a quant. correlation between viscosity and the rate of heat penetration as measured both by the apparent diffusivity and, in certain cases, by the slope of the semi-log plot. *Acidified sirups.*—Acid reduces the retardation of heat penetration. This is probably due to the reduction in viscosity caused by inversion of the sugar. The decreasing rate of heat penetration is in the direction of increasing viscosity. *Fruit juices and sirups.*—The heat penetration in the fruit juices did not differ noticeably from that of H_2O or from each other. In the fruit sirups studied it was not markedly different from H_2O , although it was slower than in a simple sirup of the same concn. In the viscous lemon concentrate (7 pts. lemon juice concd. to 1 pt. *in vacuo*) it was very markedly different from that of H_2O . With the instrument used it was too plastic for its viscosity to be detd. at 20°. *Effect of various sirups.*—Various sirups had no marked effect on the heat penetration. The retardation is not in the order of increasing concn. The effect of pectins and gums enter here. These colloids increase the viscosity of the sirup. *Effect of pectin.*—Pectin is a reversible colloid and even in solns. of $1/2$ and 1% noticeably retards penetration. Acid, here also, reduces somewhat this retarding effect. The retardation is in the order of increasing viscosity. The viscosity of the pectin solns. used was lower than that found by Wendelmuth. *Effect of pectin and sugar.*—The greater the concn. of pectin, the greater was the retardation. Acid when it did not cause jellying reduced this retarding effect. Once the soln. jellyed, the heat penetration was not influenced markedly by change in pectin content. *Effect of gum tragacanth and sugar.*—Addn. of gum tragacanth to H_2O and sirup markedly retards heat penetration. High concn. of gum tragacanth did not retard heat penetration in sirups as much as did high concns. of pectin. It is evident that the rate of heat penetration decreases with increase in viscosity of the soln. Apparent diffusivity decreases with increasing viscosity.

J. A. KENNEDY

The occurrence of starch in oil-bearing edible nuts. C. GRIEBEL. *Z. Untersuch. Lebensm.* 55, 236-9(1928); cf. *C. A.* 22, 2013.—G. demonstrated the presence of starch in sapucaja, pecan and Swiss pine nuts.

WILLIAM J. HUSA

The preservation of chestnuts in a fresh condition. E. BOTTINI. *Atti congresso naz. chim. pura applicata* 2, 1033-7(1926).—Although chestnuts preserved in an atm. of CO_2 show no change externally nor formation of mold, there is a sensible change in protein content and a loss of about 50% of sugar. Chestnuts treated with hexamethylenetetraamine have a compn. close to that of the fresh product. Part of the sugars are transformed to reducing sugars. Chestnuts held without treatment show a water content and acidity distinctly lower than the fresh product. The optimum condition of preservation consists in treatment with hexamethylenetetraamine. L. T. F.

Wyoming forage plants and their chemical composition. OTTO MCCREARY. Wyoming Agr. Expt. Sta., *Bull.* 157, 91-106(1927).—N in the total solids of the grasses and clover studied is present in largest quantity when the plants are in the stage of growth termed pasture, after which it gradually decreases until the plant is wholly dead. The same is true, in a lesser degree, of the fat and ash. After death of the grasses in the fall the dead plant may remain standing all winter without much change in chem. compn. The feeding value of these dead grasses appears to be little better than oat straw, this value showing little difference in the different species of grasses. At the higher altitudes growth of the grasses starts later, but is more rapid. "Alpine plants appear to bloom and seed almost in a day." On this account the pasture stage is hardly passed when the plants bloom and the chem. compn. of the plants of higher altitude will be nearer the pasture compn. than plants of the lower altitudes at the blooming stage. This would indicate the reason that plants of the higher altitudes contain more N than those of the lower altitudes when collected at the same stage of growth. The shading of the plants causes the prolongation of the pasture stage as indicated by the content of N, fat and ash. The fiber increases with the age of the plant whether shaded or not. The forage of the Red Desert has a very high feeding value; the leaves of the sage brush after drying have the compn. of a concentrate and the leaves of the salt sages have a nutritive value as high as the best alfalfa hay, while the dead grasses serve as roughage. E. F. SNYDER

The nutritive value of grasses, as pasture, hay and aftermath, as shown by their chemical composition. T. W. FAGAN. Univ. College Wales, Aberystwyth *Agr. Dept. Advisory Bull.* 2, 23 pp (1927).—Individual grasses show considerable variation in the % compn. of their pasture cuts, this being almost as great as the seasonal variation. Their yield and chem. compn. are to a large extent influenced by their ability to resist the cutting treatment (grazing) and by the leafiness of the growth. The oftener the grasses are cut (or the harder they are grazed) the more leafy they become and consequently the better the produce from the point of view of chem. compn. Where grazing is hard, the yield of dry matter to the animal is not so great as where the grazing is lenient, but the compn. of that dry matter is superior and does not vary to the same extent as when the interval is longer. The time at which hay is cut is a factor of the highest importance and it is better to err on the side of early rather than late cutting; an interval of a week with some grasses having a very pronounced effect on their chem. compn. Aftermaths are characterized by their leafiness, which has a considerable effect on their nutritive value. Results show that the longer the grazing of the aftermath is delayed, the heavier its yield but the poorer its quality, and that this is especially the case with the leaf portion. E. F. SNYDER

The spontaneous heating of hay. FRITZ HILDEBRANDT. *Centr. Bakt. Parasitenk. II Abt.* 71, 440-90(1927), cf. *C. A.* 21, 3240.—Fungi play a definite role in the heating of hay. It is essential to exclude as much O_2 as possible from fresh hay. J. T. M.

Precipitins obtained by means of proteins coagulated by alcohol and their specificity [distinguishing beef and pork] (NICOLAS, KATRANJEFF) 11B. Rennin coagulation of milk. Effect of hirudin, of heparin, of cephalin and of fat removal (STONE, ALSBERG) 11F. Acids of figs (NELSON) 11D. Volumetric analyses of oil cakes for their oil content and moisture (LAPTEV) 27. Obtaining average samples of oil cake (GOGOLEV) 27. Proteolytic bacteria of milk. I. A medium for the direct isolation of caseolytic milk bacteria (FRAZIER, RUPP) 11C.

COLEMAN, D. A., COLLATZ, F. A., FELLOWS, H. C., MIZE, M. D., AND MORISON, C. B.: **Methods for the Analysis of Cereals and Cereal Products.** Kansas City, Mo.: Am. Assoc. of Cereal Chemists. 176 pp. Price to members, \$3; to non-members, \$3.50. Reviewed in *Ind. Eng. Chem.* 20, 874(1928).

Food. PAO N. WOO. *Fr.* 632,800, Apr. 14, 1927. See *Brit.* 269,576 (*C. A.* 22, 1415).

Agglomerated cream. CHARLES E. NORTH (to The Milk Oil Corp.). U. S. 1,678,476, July 24. Natural cream is washed to remove substantially all non-fatty solids and the washed cream is whipped without substantially increasing its volume.

The resulting stiff pasty product is thicker than ordinary whipped cream. U. S. 1,678,477-8 also relate to whipping cream and obtaining butter fat and describe app.

"Delactating" cream, etc. WILLIAM J. McLAUGHLIN. U. S. 1,677,976, July 24. A gas-forming material such as NaHCO_3 is mixed with water in a closed vessel and steam is introduced into the bottom of the vessel to produce a gas; heated air is also introduced to cleanse the air and the gaseous mixt. thus formed is heated to $60-90^\circ$ and used for deodorizing cream or the like. An app. is described.

Cheese. SANFORD K. ROBINSON (to Kraft-Phenix Cheese Co.). U. S. 1,678,167, July 24. Cheese of a normally solid variety is comminuted, heated and stirred and during the process there is added a small proportion of Na K double tartrate.

Treating cereals. TREUHAND-GES. M. B. H. HARTMANN & Co. Fr. 633,641, Apr. 30, 1927. See Brit. 270,706 (C. A. 22, 1650).

Waste products from cereals. RENÉ A. LEGENDRE. Fr. 632,126, Apr. 2, 1927. Bran and all kinds of waste products from cereals are made alk. by treatment with basic salts or free bases to prevent fermentation.

Curing meat. SALADINE E. COLGIN. U. S. 1,678,056, July 24. A compn. for curing meat is prepd. by mixing NaCl 10 lb., sugar 2 lb., KNO_3 8 oz., black pepper 4 oz. and red pepper 2 oz. and spraying and agitating the mixt. with pyroligneous acid 16 oz. and heating until dry.

Apparatus for regulating the temperature of chocolate. NATIONAL EQUIPMENT Co. Fr. 633,625, Apr. 30, 1927.

Fruit flour. CARTEL COLONIAL. Fr. 632,227, July 9, 1926. The pulp of bananas and other tropical fruits is dried under a high vacuum in very thin layers.

Fruit sirup. ROBERT T. NORTHCUTT. Fr. 632,839, Jan. 16, 1927. A fruit sirup contains a pectin, a carbohydrate such as sugar and an acid such as malic acid, the proportions being such that the pectin does not enter into soln. with the other matters to form a gel but can form a soln. when water or more sugar is added.

Maturing fruits. DYER B. HOLMES. U. S. 1,678,046, July 24. Fruits such as dates are cut when the first of the clusters are approx. ripe and ripening is completed in a closed chamber in which the fruit may be supplied with nutrient soln. and artificial light.

Apparatus for preserving fruit or other foods by heating and treating with circulating sugar solution or other liquids. R. V. JELlicoe. Brit. 281,380, Aug. 31, 1926.

Apparatus for grinding and pressing fruits and vegetables. ÉMILE L. ASSELIN. Fr. 633,430, Aug. 23, 1926.

Pectin. SCHWARTAUER HONIGWERKE UND ZUCKERRAFFINERIE A.-G. Brit. 281,513, Feb. 1, 1927. Apples or other suitable pectin-bearing material is alternately stirred in cold weakly acidulated water and pressed to remove sol. coloring substances and sand and other associated impurities. The pectin is then obtained by repeated hot extrns. with tartaric, citric, lactic or similar acids and the solns. are purified and concd. The p_H of the concd. soln. may be adjusted to facilitate jellification.

Cooking with steam. ALFRED F. BARTLESON (to Fruit Belt Preserving Co.). U. S. 1,677,912, July 24. An app. is provided with agitators which lift the middle portion of the mass of material and expose it to steam from jets in the upper portion of the app.

Cattle food. CHRISTIAN N. KJAERGAARD. Can. 281,904, July 24, 1928. Waste org. residues from industrial plants contg. less than 16% H_2O are compressed with a binder at a pressure of 350 atm. and temp. of 50° .

Food for animals. SOC. DES SUCRERIES TERNYNCK. Fr. 633,463, Sept. 1, 1926. Pulp from sugar factories or other industries is dried and mixed with a binder such as molasses and pressed to briquets which will disintegrate on adding H_2O .

Food for animals. U. S. FARM FEED CORPORATION. Fr. 632,191, April 5, 1927. See Brit. 278,818 (C. A. 22, 2800).

13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

The chemical and allied industries. I. A general introduction to a series of articles. REX FURNESS. *Chemistry & Industry* 47, 765-7 (1928); cf. C. A. 22, 1417. E. H.

Patents and the chemist. A. B. MOULTON. *Catalyst* 13, 8 (June-July, 1928); *Ind. Eng. Chem., News Ed.* 6, No. 15, 7 (1928).—A discussion from the chem. viewpoint of the basic law which specifies the requirements of a patentable invention. E. J. C.

The influence of oil-containing incrustations in the steam chambers of evaporators on the heat transmission and the capacity of the evaporators. W. A. SPOELSTRA. *Arch. Suikerind.* 36, 429-47 (1928).—Expts. were made to find out the difference in heat transmission in clean pipes and pipes of the same material, but with an oil-contg. incrustation on the steam-side. The results showed that the usual way to clean the steam-sides of the evaporators with gasoline is not sufficient, when the incrustations contain 15-30% oil, and after cleaning with gasoline the surface of the pipe remains rough. A calcn. is given to show that the incrustation on the steam-side of the 1st body of an evaporator will cause only a small difference in capacity of the whole plant. Cleaning of the pipes of the other bodies will be necessary also. P. R. PEKELHARING

Gas distribution in liquids by means of a rotating sieve. ED. PSEHNICKA. *Z. Zuckerind. techoslav. Rep.* 52, 227-8 (1928).—When a gaseous medium is to react in a liquid it is necessary to introduce the gas in fine streams that quickly break up into small bubbles. The smaller their vol. the greater is the active contact surface, the more intimate is the contact between gas and liquid and the greater is the spread of reaction resulting in better utilization of the gas. P. achieves this by conducting the gas into the liquid through a turbine-like body, under or above which are placed rotating arms which serve to throw the gas toward a horizontal sieve which is perforated in such a manner as to force the gas through the holes on a tangent. The outflowing gas sets the entire app into rotation. A large float helps to reduce the friction caused by the wt. of the app. When rotation ceases, then the sieve, acting as a standing turbine, continues to give the liquid a rotary motion. With this gas distributor in the first carbonation tanks, P. succeeded in greatly increasing the slicing capacity for beets without having to increase CO₂ production or increasing size of carbonation station. F. R. BACHLER

Alkali, etc., works in Scotland. Report for the year 1927. J. W. YOUNG. *Annual Rept. Alkali Works* 1928, 36-41.—No serious complaints of emission of noxious gases have been made during the year. The results of inspection of alkali works, H₂SO₄, chem. manure, sulfate and chloride of NH₄ and gas liquor, tar and Zn works are outlined. Elimination of discharge of Zn vapors at Zn works seems impossible with present methods. W. H. BOYNTON

Arsenic in wall paper and window shades. K. SCHERINGA. *Pharm. Weekblad* 65, 677-9 (1928).—As is seldom found nowadays in wall paper and window shades in excess of the permissible limit of 5 mg. per sq. m. A peculiar case is reported where the odor of alkylarsines was noticed, but examn. of the outer wall paper gave a negative test for As. The older paper beneath gave, however, a strong test, the As being almost completely sol. in H₂O. It appears that the paperhanger some 15 years previously had mixed rat poison with the paste in order to prevent mice from gnawing the paper. Repapering from time to time had evidently furnished nutrient material for the fungi which converted the As into volatile compds. A. W. DOX

Classification and designation of chemical warfare agents. JULIUS MEYER. *Z. ges. Schiess- Sprengstoffw.* 23, 241-4 (1928).—About 25 chem. warfare agents were used effectively in the World War, 45 others were used exptly. or temporarily in the field, and 50 more were studied in the lab. They have been classified according to (a) chem. structure, (b) physiol. action, (c) tactical uses and (d) state of aggregation. German, French, English and American classifications according to (b) are given. The importance of ease of detection, persistence, immediate or delayed action, and time of disability, as factors in chem. warfare tactics, is discussed. J. S. REICHERT

Limiting uses for gas masks with chemical filters. WILHELM HAASE-LAMPE. *Montan. Rundschau* 20, 405-6 (1928).—See C. A. 22, 1637. W. C. EBAUGH

Operating experience with high-pressure and high-temperature steam (ORROK) 21. Measurement of steam flow in works practice (ARMSTRONG, NORDENSON) 21. Operating experiences with 1300-pound steam pressure (ANDERSON) 21.

BAUSCH, H.: Allgemeine chemische Technologie. Berlin: W. de Gruyter & Co. 155 pp. Cloth, M. 1.50.

DAMER, O.: Chemische Technologie der Newzeit. Vol. III. 2nd ed., revised by F. Peters. Stuttgart: F. Enke. 936 pp. M. 53.

MÜLLER, WOLF JOHANNES: Unterrichtsprobleme in Chemie und chemischer Technologie im Hinblick auf die Anforderungen der Industrie. Berlin: Julius Springer. 17 pp. R. M. 1.

Emulsions. G. BAUME, P. CHAMBIGE and D. BOUYIER. *Brit.* 280,930, Nov. 17, 1926. In prepg. emulsions as described in *Brit.* 255,074 (C. A. 21, 2750) and *Brit.*

256,633 (C. A. 21, 2978) the soap employed may be replaced by ingredients which react together to form soaps or by other substances having soap-like properties, *e. g.*, caustic alkali, carbonates, sulfites, alk. borates or "sulfite leaches." In prepg. emulsions such as those of bituminous materials for use on roads, inert ingredients also may be added such as kieselsguhr, asbestos, clay, wood waste or residues from fermentation processes, bone powder, slags from foundries or blast furnaces or residues from the calcination of offal.

Emulsions. I. G. FARBENINDUSTRIE A.-G. Fr. 633,661, May 2, 1927. To render anhydrous org. compds. or solns. emulsifiable in water, they are added to a compd. sol. in water such as alc. or acetone, along with salts of sulfonated mineral oils.

Separating solids. GEORGE RAW. Fr. 633,524, April 28, 1927. Solid materials are sepd. according to their sp. gr. by static air pressure. To effect this the static pressure which supports the layer of material is approx. equal to the wt. of the layer, and the layer must offer sufficient resistance to the passage of air.

Separating objects according to weight. SOC. ANON ANCIENS ÉTABLISSEMENTS BERNARD, VERRERIE DE BAGNEAUX. Fr. 633,452. Aug. 27, 1926. The objects to be sepd. are put on floats which sink more or less according to the wt. of the object. The object is thus brought opposite one of a series of compartments down which it is caused to slide.

Utilization of liquids for transmitting energy or matter. IMPERIAL CHEM. INDUSTRIES, LTD. Fr. 633,570, April 29, 1927. Turbulence in liquids, produced by causing a liquid distributed on the exterior of a tube to descend under gravity, is used for the exchange of heat or transfer of matter from or to the film or between the film and surrounding space or matter. The method can be applied to the evapn. and distn. of liquids and absorption of gases.

Gases acting on solids. I. G. FARBENIND. A.-G. Fr. 632,528, April 9, 1927. To obtain material in small pieces of uniform size for reaction with gases, drops of water or solns. are caused to fall on a layer of the powdered material and the spherical masses which are formed are sepd. by sifting and dried.

Purification of gases. DEUTSCHE GASGLÜHLICHT-ÄTHER-GESELLSCHAFT M.B.H. Fr. 632,178, Apr. 4, 1927. To indicate that gas filters are nearing exhaustion, substances which are easily perceptible and which behave toward the filter in the same way as the impurity to be removed are added to the gas, or substances which will react with the impurity to form an easily perceptible compd. are placed behind the filter.

Purifying gases. MARCEL C. E. MULO. Fr. 633,499, April 27, 1927. In app. for purifying gases in which the gas is submitted to whirling, the whirling is produced by an Archimedean screw.

Treating gases. RICHARDSONS WESTGARTH AND COMPANY, LIMITED, AND FRANCIS G. INGLIS. Fr. 633,595, Apr. 29, 1927. An app. for cooling, purifying or otherwise treating gases with liquids contains several pairs of perforated disks, one of the disks of each pair being fixed while the other turns. The gas passes through the perforations and is intercepted by a current of liquid passing radially between the disks.

Breaking or deforming a vein of liquid. ÉTABLISSEMENTS GAIFFE-GALLOT ET PILON. Fr. 633,417, Aug. 20, 1926. A vein of liquid carrying an elec. current is broken or deformed by allowing a magnetic field to act on it. The invention is applied to the starting of mercury app. without rocking, and agitating baths or liquids without mechanical means.

Drying meat, hides, wood, paper or other materials in a closed receptacle. JOSEPH P. DEVINE. U. S. 1,678,559, July 24. The material is heated under sustained reduced pressure during the entire drying operation in the presence of vapor of relatively high humidity for an extended period of time and the vapor is removed from the drying receptacle during the process. An app. is described.

Refrigerating apparatus. HELMUTH W. TOHTZ and KIRKE L. BONNELL. U. S. 1,678,171-2, July 24.

Absorption refrigerating apparatus. JENS O. BOVING. U. S. 1,678,242, July 24.

Gas adsorption for refrigerating, separating and drying gases. STUDIENGES. FÜR GASINDUSTRIE. Brit. 281,305, Nov. 23, 1926. Silica gel is produced by introducing CO₂ into a soln. of waterglass, and the gel is cooled to the b. p. of the gas to be adsorbed (the cooling being effected by evapn. of liquefied gases). In obtaining O from liquefied air, the N is used for reactivating the gel.

Refrigerating system of the adsorption type employing alcohol vapor and activated carbon. IVAR AMUNDSEN (to A/S Amundsen Refrigerator Co.). U. S. reissue 17,045, July 24. Original pat. 1,647,208 was issued Nov. 1, 1927.

Refrigerating system of the absorption type. BALTZAR C. VON PLATEN and CARL G. MUNTERS (to Electrolux Servel Corp.). U. S. 1,678,277, July 24.

Refrigerating system of the reversing absorption or adsorption type. I. AMUNDSEN (to A/S Amundsen Refrigerator Co.). Brit. 280,880, Nov. 22, 1926.

Refrigerating system employing air-vapor mixtures. W. H. CARRIER and CARRIER ENGINEERING CORPORATION. Brit. 281,356, July 20, 1926. Mech. features.

Refrigerating system for liquefaction of air or other gases. JOSEPH L. SCHLITT and WILCOTT DENNIS (to Air Reduction Co.). U. S. 1,678,485, July 24.

Compression refrigerating system. R. W. DAVENPORT (to Chicago Pneumatic Tool Co.). Brit. 281,622, Nov. 30, 1926.

Compressor for ammonia for refrigerators. LUIS DE IZAGUIRRE. Fr. 633,662, May, 2, 1927.

Electric insulators. J. E. G. LAHOUSSE. Fr. 633,171, Aug. 12, 1926. See Brit. 275,958 (C. A. 22, 2421).

Insulating cables for high-tension electric currents. BRITISH INSULATED CABLES, LTD., G. H. NISBETT and F. J. BRISLEE. Brit. 281,397, Sept. 3, 1926. Insulation such as paper is dried and the contg. vessel is subjected to as high a vacuum as practicable; the vacuum is then broken by introducing a gas sol. in the impregnating material which is to be subsequently used, e. g., CO_2 when transformer oil, refined cylinder oil or petroleum jelly is to be used; the vessel is again subjected to a vacuum and flooded with the impregnating material which has been degasified. In some cases, resin or "insulating wax" may be added.

Heat-insulation. C. O. GOSSLER. Brit. 281,490, Jan. 4, 1927. Layers of spun glass are arranged with the filaments of each layer parallel with each other but those of different layers at an angle. Some or all the layers may be impregnated with rubber, waterglass, gelatin or other materials. The insulation is suitable for use on pipes and may be wrapped with fabric.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Water supplies of the Mississippi coast. W. A. KRAMER and M. P. HATCHER. *J. Am. Water Works Assoc.* 20, 54-60(1928).—As a general thing these waters are quite soft and of a type to produce foaming troubles and embrittlement rather than scale.

D. K. FRENCH

Red water at Southern Pines, North Carolina. C. O. BUTLER. *J. Am. Water Works Assoc.* 20, 64-77(1928).—Trouble began with the use of a new earthen impounding reservoir. As the raw water could only be coagulated at pH 5.2 to 5.4, the filtered water was very corrosive. Na_2CO_3 and later lime were used and the pH was held near 7.0, and later to 8.8 and 9.0 with improved results. The discussion indicates that the use of Na silicate and CaCl_2 would give good results.

D. K. FRENCH

The water supply of Lourenço Marques, Portuguese, East Africa. R. H. FOX. *Water and Water Eng.* 36, 255-62(1928).—A detailed description of this plant.

J. A. KENNEDY

Torquay corporation water works. REGINALD V. TOMS. *Water and Water Eng.* 30, 247-54(1928).—A detailed description of this plant.

J. A. KENNEDY

Filtration improvements and economics with pre-chlorination. J. S. WHITENER. *J. Am. Water Works Assoc.* 20, 61-3(1928).—Pre-chlorination did not kill *Cyclops* in raw water. In coagulated water it reduced the turbidity, eliminated gas formers, increased filter runs over 3 times, and eliminated cracks in the filter.

D. K. FRENCH

California water chlorination survey shows steady growth. C. G. GILLESPIE. *Eng. News-Record* 100, 847(1928).—Chlorination was first practised in Calif. in 1915 at 7 plants supplying a total of 41 million gals. per day. On January 1, 1928, 68 water works, supplying 107 communities with aggregate population of 3,185,000, employed chlorination, the total vol. treated being 470 million gals. per day. The total no. of water works in the state is 662, supplying 4,340,000 people.

R. E. THOMPSON

Iron removal plant for water supply of Albuquerque, N. M. N. T. VEATCH, JR. *Eng. News-Record* 100, 845-6(1928).—The water supply of Albuquerque is derived from wells intercepting the underflow of the Rio Grande River, the composite water having the following approx. characteristics. CO_2 6 p. p. m.; Fe 0.5 p. p. m.; temporary and permanent hardness 200 and 100 p. p. m., resp. The consumption averages 1.8 million gals. per day, with max. rate of 2.7 million gals. A 5-million gal. per day Fe-removal plant is being constructed which consists of a lime-mixing tank, settling basin, alum-mixing tank and 2 filters. The mixing tanks are circular, with tangential inlets and hopper bottoms, detention period being 10 min. Mixing is effected by the motion of the water

through the tank. The settling tank is 15 feet deep and has a capacity equiv. to $1\frac{1}{2}$ hrs. flow. The filters will be operated at twice the normal rate, functioning principally as roughing filters. The effluent will be chlorinated. R. E. THOMPSON

Experimental water-filtration plant for Chicago. LORAN D. GAYTON. *Eng. News-Record* 100, 861-3(1928).—The elaborate exptl. filter plant recently constructed at Chicago at a cost of \$150,000 is described. The plant, which includes chem. soln. tanks and mixing basins of different types, coagulation and settling basins, and 12 mechanical filters of total capacity of 0.75 million gals. per day, was built to det. the most efficient and economical method of purifying the entire water supply of Chicago, now drawn from Lake Michigan at the rate of 875 million gals. per day and treated by chlorination only. R. E. THOMPSON

Municipal water-softening at St. Louis. AUGUST V. GRAF. *Ind. Eng. Chem.* 20, 758-9(1928).—Details are given on the use of lime, Al sulfate and Fe sulfate at this plant. J. A. KENNEDY

Double coagulation at Cincinnati. CLARENCE BAHLMAN AND E. B. EVANS. *J. Am. Water Works Assoc.* 20, 30-46(1928); cf. *C. A.* 22, 470, 3247. D. K. F.

Remodeling a small water purification plant. JAMES L. BARRON. *Eng. News-Record* 100, 867-8(1928).—The water supply of Burlingame, Kans., derived from an impounding reservoir on Dagoon Creek, has been treated since 1916 in a plant consisting of an alum soln. tank, coagulation basin and rapids and filter. The plant has been recently remodeled and improved by addn. of a cascade aerator, mixing flume, basin stiffing baffle and machines for applying alum, lime and Cl_2 . R. E. THOMPSON

Starting washed filters. AUGUST V. GRAF. *Eng. News-Record* 100, 867(1928).—Newly washed filters at the St. Louis plant are put in service at rate of 0.5 million gals. per day and allowed to run for 1 hr. before the rate is increased to that of the other filters. A great no. of tests have shown that the turbidity of the effluent is lower with this method than when the filter is started at normal rate. When the rate is increased to normal an increase in turbidity occurs, but the max. is less than $\frac{1}{2}$ of that when the filter is placed immediately in service at full rate. At the new Howard Bend plant being constructed on the Missouri River a new device will be employed which will slowly increase the rate of filtration from zero to the desired rate in any period of time up to 1 hr. R. E. THOMPSON

Device for collecting deep water samples. EDWARD S. HOPKINS. *Eng. News-Record* 100, 870(1928).—A brief illustrated description of a sampling app. for water at depths of 10-60 ft., which can be operated from a height of 20-80 ft. above water level. R. E. THOMPSON

Further notes on the colorimetric method for field determinations of the carbon dioxide tension of natural waters. E. B. POWERS AND J. D. BOND. *Univ. of Tennessee. Ecology* 9, 364-6(1928); cf. *C. A.* 22, 471.—An equation is mathematically developed, by means of which the CO_2 tension of a natural H_2O may be calcd. after making 3 pH detns. T. S. CARSWELL

The Gersbach indole method for judging the condition of water. W. BLUMENBERG. *Univ. of Bonn. Centr. Bakt. Parasitenk. I Abt.* 107, 386-92(1928).—Indole production, is not a consistent characteristic of the colon bacillus; hence as a test for fecal contamination it may give false negatives. Other water bacteria, especially *B. cloucae*, may produce indole and give false positives. JOHN T. MYERS

Operating problems of pneumatic alum conveyor system. J. ARTHUR JENSEN. *Eng. News-Record* 100, 931(1928).—When the pneumatic filter alum conveyor was installed at the new Fridley filtration plant in Minneapolis it was equipped with rotary locks for delivery of the alum from the receivers to atm. pressure. These have been found unsatisfactory in that alum dust enters the drum bearings and causes friction. "Stop" or gate locks have been substituted and found satisfactory. An intensely hard scale accumulated at the bends in the iron conveyor line, reducing the capacity of the plant. This difficulty has been eliminated by substituting flanged rubber hose at the bends. R. E. THOMPSON

Use of exchange-silicate (zeolite) water softeners in railroad practice. GEORGE L. BAXTER. *Ind. Eng. Chem.* 20, 755-8(1928).—Exchange-silicate (zeolite) treatment at certain points on the Southern Pacific Lines has been found less expensive than treatment with lime and soda ash and has resulted in more satisfactory operation of stationary and locomotive boilers. J. A. KENNEDY

Deconcentrating treatment of boiler water. H. L. GRIFFIN. *Power Plant Eng.* 32, 869-70(1928).—Continuous blow-down is made economical by utilizing heat of blow-down water to heat fresh feed-water. Regulators make it impossible for blow-down water to leave the deconcentrator before its temp. has reached 65°F. S. D. POARCH

Illinois Central cleans well screens with acids. C. R. KNOWLES. *Railway Engineering and Maintenance* 24, 202-4(1928).—The Ill. Central R. R. recently cleaned the screen in a 16-inch well 258 ft. deep at Pesotum, Ill., with com. HCl, using 800 gal. acid to form 30% soln. The acid was allowed to stand in the well 24 hrs. before the pump was started and the well thoroughly flushed. The yield was increased from 42 to 140 gal. per min.

R. C. BARDWELL

The value of boiler water treatment to the mechanical department. J. F. RAPS. *Proc. Am. Ry. Eng. Assn.* 29, 1022-4(1928).—Review of improvements effected on the Ill. Central R. R., by water treatment.

R. C. BARDWELL

Circulating system in the Coffin Feedwater heater. ANON. *Railway Age* 84, No. 24A, 1420-40(1928).—Diagram and method are shown for installing and operating a feed-water heater on a locomotive.

R. C. BARDWELL

New water supply facilities effect economies on the Southern. ANON. *Railway Age* 84, 1329-32(1928).—The Southern Ry. recently completed extensive improvements to the Yadkin River plant at their Spencer, N. C., terminal. A 2,500,000-gallon sedimentation basin is provided with facilities for alum and dry sodium aluminate treatment. Present consumption averages 1.3 m. g. d. Automatic elec. control is provided for raw water and transfer pumps.

R. C. BARDWELL

The treatment of water for locomotives from the standpoint of chemical engineers. WM. BARR. *Proc. Am. Ry. Eng. Assn.* 29, 1025-31(1928); cf. C. A. 22, 834.—General discussion of railway water treatment problems including compds., lime-soda and zeolite methods.

R. C. BARDWELL

Boiler-feed water treatment from a manufacturer's viewpoint. J. B. ROMER. *Proc. Am. Ry. Eng. Assn.* 29, 1032-7(1928).—A general review of boiler-feed water impurities and their effect.

R. C. BARDWELL

Pretreatment of boiler-feed water. C. R. KNOWLES. *Proc. Am. Ry. Eng. Assn.* 29, 1045-51(1928).—Review of lime-soda and lime-soda-zeolite methods.

R. C. B.

Foaming of locomotive boilers with special reference to the influence of suspended matter on foaming and cost of blow-down. COMM. REPT. *Proc. Am. Ry. Eng. Assn.* 29, 143-52(1928).—General review with charts and tables indicates that foaming in locomotive boilers will vary with type, character and amount of suspended solids, and also with the type of work being handled by the locomotive.

R. C. BARDWELL

Cost of blow-down of locomotive boilers. R. A. TANNER. *Proc. Am. Ry. Eng. Assn.* 29, 152-5(1928).—Foaming point must be detd. for individual district and conditions after which amount of blow-down and cost can be calcd. Formula and chart are included.

R. C. BARDWELL

Carbonate and sulfate waters. Their relative influence on the operation and maintenance of boilers and their comparative costs of purification. COMM. REPT. *Proc. Am. Ry. Eng. Assn.* 29, 156-7(1928).—Cost per lb. for treatment varies from 0.44 c. for CaCO_3 to 1.66 c. for MgSO_4 . Cost in blow-down water for Na_2SO_4 averages 4 c. per lb. and soft sludge and suspended matter about 1 c. per lb. unless blown out by necessity for reducing alk. concn.

R. C. BARDWELL

Drinking water conditions on railroads during the Mississippi flood. COMM. REPT. *Proc. Am. Ry. Eng. Assn.* 29, 126-30(1928).—Emergency liquid-chlorine treatment was installed in larger towns by State Health Departments. Railroads issued bulletins recommending treatment of small supplies with $\text{Ca}(\text{OCl})_2$ on the basis of 1 ounce per 1000 gal. Boiling water was not found reliable. Experienced supervision was provided where possible.

R. C. BARDWELL

Causes of boiler pitting and means of prevention in neutral and alkaline waters. C. H. KOVL. *Proc. Am. Ry. Eng. Assn.* 29, 131-3(1928).—General review.

R. C. BARDWELL

The prevention of boiler pitting in neutral and alkaline waters by the exclusion of dissolved oxygen from the feed-water. C. H. KOVL. *Proc. Am. Ry. Eng. Assn.* 29, 133-5(1928).—Operation of locomotives equipped with an open feed-water heater in the alkali water district on the C. M. & St. P. Ry., during the past 3 years has shown good results in reduction of pitting and corrosion compared with similar engines in similar service not so equipped. The av. removal of dissolved O was 60%. Inaction of the remaining O is accounted for by the surge of water in locomotive boiler. Details and regularity of operation are important.

R. C. BARDWELL

Feedwater heaters reduce pitting. C. H. KOVL. *Railway Age* 84, 629-30(1928).—Weekly examn., over a period of 30 months, of flues in locomotive boiler equipped with open-type feed-water heater operating between Sioux City, Ia., and Mitchell, S. D., on the C. M. & St. P. Ry., developed a practical absence of pitting while similar locomotives not so equipped pitted badly. The test indicates that elimination of O by open-

type locomotive feed-water heater will greatly retard boiler corrosion in water high in alkali salts, which otherwise pit, although NaOH is present. In addition, the fuel saving averaged \$1000 per year.

R. C. BARDWELL

Prevention of pitting and corrosion by electrochemical polarization. L. O. GUNDERSON. *Proc. Am. Ry. Eng. Assn.* 29, 135-9(1928).—Three years' test on the Chicago and Alton R. R., with an electrochem. polarization system installed in locomotive boilers using weak arsenic soln. and e. m. f. of 2 v. and c. d. of 0.001 to 0.002 amp. per sq. ft. protected surface, has shown good results in relieving pitting and corrosion conditions.

R. C. BARDWELL

Sodium aluminate as an aid to water softening. COMM. REPT. *Proc. Am. Ry. Eng. Assn.* 29, 138-9(1928).—Sodium aluminate used in the lime-soda process of water softening hastens reaction time, improves coagulation and sedimentation, and reduces trouble from after-precipitation. Expts. are being conducted with dry Na aluminate.

R. C. BARDWELL

Use of sodium aluminate on the Rock Island Lines. PAUL M. LABACH. *Proc. Am. Ry. Eng. Assn.* 29, 139-42(1928).—Advantages gained by use of sodium aluminate are: (1) Increased plant capacity; (2) less residual hardness in treated water with smaller lime-soda overtreatment; (3) less alkali salts in treated water with reduction in foaming; (4) reduction in after-precipitation and improvement in pipe-line conditions. At 25 plants, Na aluminate is used without addn. of lime or soda ash.

R. C. BARDWELL

Embrittlement of steel. ALEXANDER G. CHRISTIE, et al. *Proc. Am. Ry. Eng. Assn.* 29, 1062-74(1928).—A general review of controversy on the effect of various mineral constituents in boiler-feed water on the embrittlement of boiler metal indicates a need for further study and research.

R. C. BARDWELL

Waste-water distributing devices. A. BATTIGE. *Apparatebau* 40, 162-3(1928).—Description of revolving sprays and trough distributors.

J. H. MOORE

Treatment of waste waters. T. J. LAFRENIÈRE. *Can. Chem. Met.* 12, 196-7(1928). (In French).—An address dealing with the disposal of industrial waste waters and particularly of sewage, and outlining the general policy adopted in the Province of Quebec in this respect.

A. PAPINEAU-COUTURE

The effect of sea water on the development of hookworm ova and larvae (*Necator americanus*). F. C. CALDWELL AND E. L. CALDWELL. *J. Parasitol.* 13, 270-82(1927).—Under conditions of satn., sea water has a marked lethal effect on the development of hookworm ova to the infective larval stage, 600 times that of fresh water under like conditions. Under optimum cultural conditions, the lethal action of sea water was demonstrated by an av. larval yield of 0.1% in contrast with 67.6% from cultures moistened with tap water. From feces contg. viable hookworm ova submerged under sea water for more than one day and transferred to favorable conditions of temp., soil and moisture, the larval yield was consistently low, averaging 0.75% from all cultures. Study of the process in detail showed that sea water does not prevent the development of hookworm ova to the embryo stage, but does retard the hatching of the embryos, and kills the newly hatched larvae.

C. R. FELLERS

Disposal of sludge at water-softening plants. COMM. REPT. *Proc. Am. Ry. Eng. Assn.* 29, 187-93(1928).—Where low land or flowing stream is not available, accumulation in pits with periodic cleaning and removal or direct removal in specially designed sludge cars is necessary. Plans and diagrams of typical installations are shown.

R. C. BARDWELL

Volatile acids in digesting sewage sludge. H. HEUKELEKIAN. *Ind. Eng. Chem.* 20, 752-5(1928).—Various methods for the detn. of volatile acids in digesting sewage solids have been studied. One detn. gives an accurate picture of the course and completion of digestion. When digestion is completed as indicated by solids and ash figures, the volatile acids have practically disappeared. The volatile acids in unseeded and unlimed material reach a high peak shortly after the digestion has started and persists for the whole digestion of 8 to 9 months. About half of the acids are free and can be distd. without acidifying the sample to free them. In the limed unseeded material there are no free volatile acids, but the total volatile acids reach a high peak early in the digestion period and then drop very rapidly to a low level, so that within 100 days when digestion is completed the volatile acids are at a low level. In properly seeded fresh solid mixts. there are no accumulated free volatile acids. The magnitude of the "total" volatile acids is lower than in unseeded limed material and a low point is attained earlier in the limed unseeded material. There is an intimate relation between volatile acids and gas production. Completion of digestion or the ripeness of a sludge can be detd. by measurement of volatile acids in conjunction with the other well-known tests.

J. A. KENNEDY
